showed abnormal physical signs in the chest; of 19 cases with a limited household infection only four were free from signs of the disease, while of 19 cases with a severe household infection five were free from physical signs of the disease. It was found that the reflex bands of impairment suggestive of active lung involvement showed a notably higher incidence in the first two classes than in the last, suggesting that with longer exposure the active processes have time to die down. Enlarged supraclavicular glands were found in a few cases and appeared to be of some value where found. Radiographical examination for the most part accorded with the clinical findings in this series. Wherever clinical evidence of the involvement of the tracheo-bronchial glands existed this was confirmed by the *x*-ray. In a few cases radiograms showed tracheo-bronchial opacity unnoted at the clinical examination. Bifurcation glands were visible in nearly all cases on the oblique radiogram; evidently a definite degree of enlargement is necessary to produce the characteristic right paravertebral dullness observed on clinical examination. The relation of hilum opacities to pulmonary glands could not be clearly established. In commenting on his observations in this series of cases the author expresses the opinion that it serves to increase our sense of the artificiality of the distinction between tuberculous "infection" and tuberculous "disease," and that it not only appears that tuberculous infection is widespread, as has long been known, but also actual tuberculous disease of a degree that can be detected clinically. These facts would seem to call for a readjustment of our clinical concepts.

5. **Treatment of Cloth by Antiseptic Substances in Relation to Wound Infections.**—Mary Davies, in collaboration with Kenneth Taylor, has made an investigation to ascertain whether antiseptic substances incorporated with cloth will have any power to inhibit the growth of bacteria after the cloth so treated has been exposed to the open air for some time before being heavily infected. A variety of antiseptics were tested, the one finally chosen for further experimentation being pyxol, a compound of cresols and soft soap. This compound has the advantages of being easily procurable, fairly inexpensive, and inoffensive as regards color. Garments are saturated with a 5 per cent. solution and worn before the antiseptic has thoroughly dried on them. Experimentally it has been possible to prevent cloth from becoming a focus of infection in the test tube and in wounds by treating it with an antiseptic before it is contaminated with infected material. Some degree of bactericidal value is retained even after a month's constant exposure to hot sun and storms of rain. An open wound coming into contact with antiseptic clothing would be less likely to become badly infected, even if both clothes and skin were extremely dirty at the time, than is the case where neither clothes nor skin have any property of inhibiting the growth of bacteria with which they become saturated during trench fighting. If these deductions prove correct the practice of periodically impregnating the clothing of armies upon active service with an antiseptic would fully repay its cost in reducing the proportion of highly septic wounds. Antiseptics of the cresol type seem to be most useful and practical.

1. Radical Abdominal Operation for Carcinoma of the Cervix Uteri: Result of One Hundred Cases Reckoned on an Absolute Cure Basis. Comyns Berkeley and Victor Bonney.
2. The Use of Insecticides Against Lice. A. Bacot.
3. A Fatal Case of Gastroenteritis Due to *Bacillus Aertrycke vel Suipestifer*. E. J. McWeeney.
4. Perchloride of Mercury Poisoning by Absorption from the Vagina. A. F. Wilkie Millar.
5. Case of Puerperal Septicemia Treated by Autogenous Vaccine, with Recovery. William Grier.
6. A New Solid Medium for the Isolation of the Cholera Vibrio. H. Graeme Gibson.
7. Note on the Value of Hexamine in Aural Suppuration and in Meningitis. Douglas Guthrie.

1. **The Radical Abdominal Operation for Carcinoma of the Cervix Uteri.**—Comyns Berkeley and Victor Bonney report their experience with a series of 100 cases of carconoma of the cervic uteri operated on between April, 1907, and September, 1911, by the radical abdominal method, using a very thorough operation consisting of the removal of the uterus with its cervix contained in a bag formed of the upper half or two-thirds of the vagina, closed by a clamp, designed for this purpose. The ovaries are removed with the uterus and upper portion of the vagina, also the Fallopian tubes, broad ligaments, parametric and paravaginal tissue down to the upper surface of the levator ani, and the glands and cellular tissue occupying the obturator fossæ and investing the external and internal iliac arteries and veins. In cases in which the glands about the external iliac artery and vein are obviously carcinomatous, the dissection is carried up to the bifurcation of the aorta. The results of the operation in this 100 cases, among which were many who had been dismissed from other hospitals as inoperable, were as follows: Died of the operation, 20; died of recurrent growth, 32; died of other diseases, 2; lost sight of, 7; cured, 39. In every case the regional glands removed at operation were microscopically examined, and in thirty-five were found to be malignant. Of the thirty-nine cured cases all were known to be well at the present time. These writers report an operability rate of 62.5 per cent. and have found from the large number of cases they have dealt with that patients suitable for operation presenting themselves to the surgeon for the first time have, on an average, had symptoms for six months. The life expectation of these women is, therefore, on an average one year and three months. It may, therefore, be stated with confidence that where the patient survives the operation for three years or over, her life has been prolonged by the operation. On this basis the present series showed that out of eighty cases that survived the operation, forty-nine, or 61.2 per cent., had their lives prolonged.

2. **The Use of Insecticides Against Lice.**—A. Bacot describes the various experiments that he has made to determine the insecticidal effect when substances were used in diluted condition to impregnate cloth. Cytisine was found satisfactory from an experimental point of view, but offered the objections that in the concentration in which it was effective it might have a toxic effect and the cost of production would make it an expensive remedy. Further experiments suggest that a practical remedy may be found for preventing the spread of lice among troops by the use of a crude liquid carbolic acid and soft soap emulsion for the impregnation of shirts and underclothing. The emulsion should consist of 45 to 50 per cent. of soft soap, combined by heating with 50 to 55 per cent. of the crude carbolic. A 5 per cent. solution in warm water should be used to impregnate the garments. To determine the practicability of this suggestion tests should be made to ascertain the percentage of men likely to have irritable skins which might be susceptible to this percentage of cresol and the efficacy of the remedy to keep the men free from lice in the field.

4. **Perchloride of Mercury Poisoning by Absorption from the Vagina.**—A. F. Wilkie Millar reports a case of perchloride of mercury poisoning which occurred as the result of placing a tablet in the vagina under the impression that it would serve the same surpose as when

dissolved and used as a douche. Twelve hours later the symptoms of poisoning appeared and progressed rapidly to a fatal termination. Particular interest attaches to the typical nature of the symptoms produced and the manner in which mercury picks out the lower end of the small intestine, the cecum, and the ascending colon as its selective site. The changes found in the kidneys showed the marked action of the mercury on this organ. This case is also interesting from its medicolegal aspect.

6. **A New Solid Medium for the Isolation of the Cholera Vibrio.**—H. Graeme Gibson describes his method of preparing an alkaline medium, which possesses differentiating properties which should be especially useful in the detection of cholera carriers, as the feces emulsified in broth can be plated directly on it. The method is based on the fact the cholera vibrio alone of all the intestinal organisms acidifies starch. In the case of water examination, after enrichment in peptone water for a few hours, a drop or two of the peptone water is plated and a tentative diagnosis can then be arrived at in eighteen hours owing to the allied vibrios taking a longer time than the true cholera vibrio to bring about acid production. After forty-eight hours, if the cholera colonies are in excess and the plate spread somewhat thickly, the medium itself becomes distinctly acid, and colonies other than those of cholera take on a distinctly pink tinge; the cholera colonies, however, can still be distinguished by their deeper red center which other colonies lack.

7. **Note on the Value of Hexamine in Aural Suppuration and in Meningitis.**—Douglas Guthrie has made a number of experiments to determine the correctness of the findings reported by Crowe that hexamine given by the mouth could be detected in the cerebrospinal fluid withdrawn by lumbar puncture one hour later, and that after the subdural inoculation of dogs and rabbits with streptococci the administration of hexamine appeared in many cases to avert the onset of meningitis. Barton, following up these observations, suggested that the drug might be useful in middle ear suppuration as he had been able to recover it from aural discharges. The writer finds two sources of fallacy in the results and deduction of these workers. First they employed Hener's sulphuric acid test, which does not differentiate between the drug hexamine and its decomposition product formaldehyde. Secondly, hexamine is not split up and hence can be of no antiseptic value in any but an acid medium. Ear discharges and cerebrospinal fluid are alkaline. His experiments show that after the administration of hexamine it appeared in the urine in all cases, but in no instance could it be detected in the aural discharge even when the most delicate test, the Rimini-Burnam reaction, was employed. The drug was given in large doses and symptoms of intolerance appeared in two cases. With regard to the cerebrospinal fluid, results seem to point to a similar conclusion, either that the drug does not make its way into the fluid at all or appears in such small quantities as to be of no therapeutic value. Intradural injections of hexamine may conceivably have some effect on the meninges near the site of injection, but oral administration is useless.

Revue Médicale de la Suisse Romande.

The Von Pirquet Reaction in the Schools of Lausanne.—Weith, after a general outline of the results of this reaction and of the incidence of tuberculosis, states that Lausanne has a comparatively low death rate for this affection, one, moreover, which is virtually stationary. In comparison with other Swiss cities, however, it is high, and it has been proposed to use the von Pirquet in the schools. Is it wise to test thousands of children with the result that a few more lives may be saved? According to authorities 95 per cent. of all children are tuberculous, *i.e.* have the condition in a latent form. What would be the good if all were "pirquetized?" By rights, according to theoretic conditions, one would need to be "pirquetized" weekly, for those not infected could readily become so. Would a negative reaction guarantee that a child was not tuberculous? The advocates of the test admit that such children as are candidates for tuberculosis betray this lack of resistance in many ways. These are the real suspects. Nevertheless should universal tests be practised? To cause a reduction in the incidence of tuberculosis prophylaxis seems the logical course. This means general sanitation, rigidly carried out, plus school hygiene. The author and other opponents of "pirquetization" are not opposed to the test *per se*, *i.e.* they have no fear of complications, nor do they shrink from the physical effort, nor are they old fogies. The task, however, increases with each year because both positives and negatives must be followed up, along with all new pupils. There can be no common ground between "pirquetization" and vaccination for smallpox, for the latter is meant to protect directly the individual and the public.

Progressive Lipodystrophy in a Child.—Boissonnas relates the case of a boy of six years, of good antecedents, and normal in appearance until three and one-half years of age, when he developed whooping-cough, with sequential emaciation of the face. Later he was attacked by influenza, as a consequence, perhaps, of which he developed a nephritis. The lipodystrophy may or may not have been determined or aggravated by some of these illnesses, but only the pertussis seemed responsible for its onset. Examined he showed normal growth, skeletal configuration, etc., but the face showed a remarkable contrast to the rest of the physique, which in general was in a flourishing state. The face was thin and pinched, the cheeks furrowed, the eyes sunken. The skin of the face was supple and normal, but contained no subcutaneous fat. The muscles of the face were all intact as were those of the tongue. The neck was thin, and one did not encounter a panniculus until the level of the clavicles and upper border of the scapulæ. The panniculus of the trunk was normal. There was an accumulation of adipose on the buttocks and upper portion of the thighs. The genitals were well developed. The legs were plump, but there was no obliteration of the knees and malleoli or dorsum of the foot. Of the cases of this malady on record the majority have been in females. Thus far treatment is without influence on the progress of this dystrophy.

Hydrophobia in the Foxes of Alaska.—Captain Ferenbaugh, U. S. Army, mentions the fact that so-called crazy foxes were seen in the Yukon Delta region in the spring of 1915. With mouths hanging open and dripping with foam they would approach settlements and try to bite the dogs. Demented, stiff, and emaciated, they were easily killed. Nevertheless five dogs were bitten and succumbed to rabies. In the interior of Alaska the disease seems to have been unknown until 1914, when a man died of the disease three weeks after the bite of an Esquimaux dog. During the crazy fox episode a soldier was bitten by one of the infected dogs. He was hurried to San Francisco, took a Pasteur cure and has since remained well. The Esquimaux have in general regarded the craziness of the fox as the result of starvation. But any naturally shy animal which unprovoked attacks men and dogs is best regarded as rabid.—*The Military Surgeon.*

Book Reviews.

THE INFLUENCE OF JOY. By GEORGE VAN NESS DEARBORN, Instructor in Psychology and in Education, Sargent Normal School, Cambridge, Mass., etc. (Mind and Health Series. Edited by H. ADDINGTON BRUCE, A.M.) Price, $1 net. Boston: Little, Brown & Co., 1916.

SEVERAL books have already appeared in this series, which might be called one of popular psychology. This volume is based chiefly on certain experiments made by the author and others demonstrating the physiological effect of certain emotions, particularly the benign one of joy, on bodily systems. The whole theory is, of course, a further application of the conditioned reflex as discovered by Pavlov in the last decade of the Nineteenth century. It is, in fact, a scientific support of the "New Thought" doctrines formulated for popular reading. The only defect is that while admittedly a book primarily for popular consumption, the writer finds difficulty in reaching the level of his audience. Thus we have such statements as "Kinesthesia may be considered the dynamic index of organism always in motion in relation to mind, and in emotion this principle is more obvious than elsewhere" (p. 21). And again, "Suggestion then is the more or less impulsive determination of a motive through influence exerted on the associative 'resultants' of the cortex, and implies a lessened control from the more purely voluntary and personal correlations as well usually as a narrowing of the field of consciousness" (p. 139).

Dr. Dearborn in the first part of his book describes the action of joy in stimulating secretions in the gastro-intestinal tract, its influence on the circulation; he describes the effect of good humor and enthusiasm on the nervous system, and finally its beneficent effects on the love-life. In the second part he lays down a philosophy of life something after the style of the Cheeryble brothers. He indicts in somewhat familiar phraseology the fiends of indolence and worry and praises work and play, both to be done of course with an ostentatious joyousness. Finally he alludes to the pragmatic side and points out the economic value of joy to the world.

The latter part of the book has a much wider appeal than the earlier part and is much easier for the lay reader to understand. The book as a whole should find its audience chiefly among physicians, educators, nurses, and employers of labor.

DIET FOR CHILDREN, A Complete System of Nursery Diet with Numerous Recipes; Also Many Menus for Young and Older School Children; A Home and School Guide for Mothers, Teachers, Nurses and Physicians. By LOUISE E. HOGAN (Mrs. JOHN L. HOGAN). Author of "How to Feed Children," "A Study of a Child," "The Introduction of Domestic Science in the Schools of New York City," U. S. Government Bulletin No. 56, etc. Price $.75. Indianapolis: The Bobbs-Merrill Company, 1916.

ONE of the most hopeful signs in these times of restless feminine activity is the awakening to the needs of rational and thoroughly intelligent feeding not only of babies but of children and older boys and girls, by the mothers and other women engaged in caring for the young of the race. Louise Hogan has made a successful attempt to meet this demand. She quotes the great Abernathy in saying that one-fourth of what we eat keeps us and the other three-fourths we keep at the peril of our lives. This book is a wise endeavor to reduce this peril.

OBSTETRICS NORMAL AND OPERATIVE. By GEORGE PEASLEE SHEARS, B.S., M.D. Professor of Obstetrics and Attending Obstetrician at the New York Polyclinic Medical School and Hospital; formerly Instructor in Obstetrics, Cornell University Medical College; Attending Obstetrician at the New York City Hospital; Senior Attending Obstetrician at the Misericordia Hospital. With 419 illustrations. Price, $6.00. Philadelphia and London: J. B. Lippincott Co., 1916.

THROUGH the irony of circumstances, the author of this work died suddenly while the result of his labors was going through the press. His aim, although he was of scholarly cast of mind, was to produce a purely practical book and in this he has succeeded well, although not a few treatises on obstetrics are written with this very aim. The more practical a book the more individualized it must be, for it is certainly not altogether practical to cite the teachings of other men save when the latter are endorsed fully by the author from his own experience; and the author has certainly written a personal book. In turning over the pages we see relatively few citations. As a test, under obstetric surgery, we do not find mention of a single contemporary author in forty consecutive pages of text, and this is not an isolated instance. On the other hand he has borrowed illustrations very freely, with due credit to the source. In regard to the burning questions of the day he advocates a partial substitute for twilight sleep —two small injections of morphin-hyoscin in the first stage. He does not even mention nitrous oxide under anesthesia, save that in obstetric operations "it should never be given until after delivery." In puerperal sepsis he is a strong advocate of the serum treatment. He prefers Dew's method in asphyxia neonatorum and of mechanical methods Holden's apparatus. The general attitude of the author is conservative, which is no doubt wise from the teaching standpoint. Still the public is entitled to a full mention of recent matter of importance, which might be given in fine print, or in some other way which would not interfere with a conservative attitude in the principal text. There is a very large per cent. of students who wish to lean, and rather heavily, upon a one-man text-book while others differently constituted, find the study of such a work a useful discipline, for they too must in time depend chiefly upon the results of their own experience for practice and teaching. Hence Dr. Shear's book should meet with a ready sale.

OPERATIVE MIDWIFERY. A Guide to the Difficulties and Complications of Midwifery Practice. By J. M. MUNRO KERR, M.D., C.M., Glas. Fellow of the Royal Faculty of Physicians and Surgeons, Glasgow; Hon. Fellow, American Gynecological Society; Professor of Obstetrics and Gynecology, Glasgow University (Muirhead Chair); Obstetric Physician, Glasgow Maternity Hospital; Gynecologist, Royal Infirmary, etc. Third edition. Price, $6. New York: William Wood & Company, 1916.

THE first edition of this work appeared in 1908 as a successor to the volumes on the same subject by Barnes and Herman. The present edition contains twenty more pages of text and fourteen more cuts than the original book. When we bear in mind that the work is for all practical purposes a manual of operations and that only accredited procedures can be recommended, and also that it is very largely a personal book, we can understand why numerous remedies are omitted, such as mechanical methods of reanimating the newly born, lumbar puncture in eclampsia, etc. On the other hand, the new edition is particularly full on cesarean section, the number of indications for the latter being now very large. The book is a worthy successor of Barnes's "Obstetric Operations" and Herman's "Difficult Labor."

ABNORMAL CHILDREN (Nervous, Mischievous, Precocious, and Backward). A book for Parents, Teachers, and Medical Officers of Schools. By BERNARD HOLLANDER, M. D., Author of "The Mental Functions of the Brain." Price, $1.25 net. London: Kegan Paul, French, Trubner & Co., Ltd. New York: E. P. Dutton & Co., 1916.

AS noted on the title page, this book is addressed to an audience chiefly lay in character, and is subject to the implied limitations. It is, as a matter of fact, a brief description of feeblemindedness, precocity, and neurotic manifestations in children, with some glittering generalities offered in the way of treatment. As often happens to the writer who attempts to present medical matters in a popular vein, the author is obliged to be superficial and dogmatic, at times even to the verge of misrepresentation. Thus he says, "Heredity is by far the most frequent and the most potent predisposing cause of nervous and mental disease." And again, "A man who can drink continually for a number of years and keep out of a lunatic asylum, a prison, or a hospital, must possess an inherently stable physical and mental organization." Like most English writers, he uses the unfortunate terms "lunatic" and "insane" freely. He also speaks of sexual immorality as if it were peculiar to urban life, says that somnambulists can read, and after alluding to the Binet-Simon tests in a paragraph, makes the interesting observation that they have been criticized as not being individual enough, and concludes by saying, "Anyhow, the principle is right, and it should be easy to improve upon the details." Goddard, Yerkes, Bridges, Healy, et al., take notice! But aside from these statements, to which the hypercritical might take exception, as they might to his individual phrenology, the book is quite readable, and we should imagine could not be read by the parent or teacher without benefit.

Society Reports.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Sixty-sixth Annual Session, Held at Scranton, September 18, 19, 20, *and* 21, 1916.

(Special Report to the MEDICAL RECORD.)

(*Continued from page* 701.)

SECTION ON MEDICINE.

Chairman's Address.—Dr. J. WESLEY ELLENBERGER of Harrisburg referred to the average increase of human life from twenty-five years in the sixteenth century to forty-seven years at the present time, which increase he attributed to the work of the medical profession. He suggested as possibly an ideal system for the better service of the many the grouping in one building of an internist, a surgeon, a laboratory man, and other specialists with individual offices; the fees to be divided according to the amount of service given and in harmony with established prices. Attention was called to the prospective health insurance bill and the co-operation of physicians urged that a satisfactory bill might be presented to the Legislature.

Types of Pneumococci in Infants and Children.—Dr. A. GRAEME MITCHELL of Philadelphia said the present study was undertaken to ascertain whether the same types of pneumococci were present in infants and children with pneumonia as in adults. He found that the so-called fixed types of pneumococci were of infrequent occurrence in infants and children as compared with adults; that the pneumococci without definite agglutination reactions and classed as Type IV were of more frequent occurrence in infants and children than in adults; that the mortality of infants and children infected with the fixed types (I, II, III) seemed to be lower than in adults. The fixed type occurred at all ages from six months to eleven years. Type IV was found often to cause as severe an infection as the fixed types. Type I seemed to cause a mild infection. Type IV was found to be the most frequent infecting organism in bronchopneumonia, although the fixed types might be found. Complications were found more frequently with Type IV.

The Specific Treatment of Acute Lobar Pneumonia.—Dr. RUFUS COLE of New York stated that the specific treatment of a disease consisted in treatment directed toward the destruction or inhibition of the growth of the etiological agent in the body, or neutralization of the injurious substances produced by this agent. With present knowledge, specific treatment might consist in the employment of drugs having a specific action (chemotherapy) or the use of measures based on established principles of immunity (immunotherapy). In the latter case, at least, exact knowledge of the etiologic agent in each individual case must be obtained. This, he said, was especially important in pneumonia, for different races of pneumococci showed well-marked immunological differences, there being at least four different types of pneumococci. Methods were now known for determining quickly in each individual case the type of pneumococci concerned. To increase the patient's resistance, it was observed that he might be stimulated to produce immune bodies himself (by the employment of vaccines) or immune bodies might be administered to him by giving him immune serum. At present the author stated that there was no experimental evidence and no conclusive clinical evidence indicating that the first method was effective. There was reason for believing, however, that the use of immune serum would be of value. Clinical experience indicated that an immune serum effective against Type I pneumococci had great clinical value. Immune sera against the other types, however, were at present not of therapeutic importance. The only specific chemotherapeutic agent against pneumococci now known was ethylhydrocuprein (optochin.) In the employment of this drug proper dosage was said to be of fundamental importance. The proper dosage had been determined through experimental and clinical studies. Clinical studies, employing this proper dosage, suggested that this drug might be of considerable therapeutic value.

The Treatment of Pneumonia by Other Than Specific Methods.—Dr. M. HOWARD FUSSELL of Philadelphia regarded fresh air, rest and most vigilant watchfulness as the principal factors in the care of croupous pneumonia. Cardiac weakness demanded digitalis, caffeine, camphor. Food should be nourishing and of moderate amount. Alcohol was of use when there had been addiction during health. It was useful as a food in small quantities, not more than 2 or 3 ounces in twenty-four hours. Strychnine might be given fairly continuously.

Dr. LAWRENCE LITCHFIELD of Pittsburgh, discussing Dr. Mitchell's paper, referred to Type IV being the infection most frequently found in children, and suggested in this type the term "Group" rather than Type, since this group was made up of different types. Regarding Dr. Fussell's paper he emphasized especially the importance of keeping the patient warm when he was being cared for in a cold room or on the porch. There should be plenty of woolen blankets under the patient as well as sufficient covering over him, and if the weather were very cold he would put the patient between blankets. He also emphasized the value of using abundance of water. If not readily taken by the mouth it should be used intravenously and with dextrose rather than sodium chloride.

Osteomalacia.—Dr. LAWRENCE LITCHFIELD of Pittsburgh gave a brief consideration of skeletal disorders more or less closely related to osteomalacia; different theories as to etiology—disorders of the ductless glands, acidosis, calcium metabolism and infection, with report of a case. In conclusion the author said that it would seem that at the present time the rational procedure is a case of osteomalacia should be an attempt to secure the best possible hygienic environment, a generous diet, rich in phosphorus and calcium, the avoidance of termination of lactation, the avoidance of pregnancy, adrenalin therapy, and if no improvement were noted, sterilization of the patient by the *x*-ray; if then no improvement, ovariectomy, possibly followed by a return to the administration of phosphorus and the hypodermic use of adrenalin.

Acidosis.—Dr. J. HAROLD AUSTIN of Philadelphia defined acidosis as an abnormal diminution in the amount of carbonates and phosphates of the blood. To the severe grades of acidosis having the peculiar hyperpnea without cyanosis he applied the term acid intoxication. For determining the mild forms of acidosis and the more accurate diagnosis of all forms mention was made of several of the newer laboratory methods. The depleted base in the blood should be replaced and this was best accomplished by the administration of bicarbonate of soda. Alkali might bring about a cessation of the hyperpnea of acid intoxication and diminish the laboratory evidence of acidosis. In the severest cases of acid intoxication, however, death occurred even when the urine had been rendered alkaline.

Dr. ALFRED STENGEL of Philadelphia called attention to the tendency of overlooking subsidiary conditions of greater importance perhaps than the definite ascertained disease under treatment. This tendency was particularly to be remembered in the treatment of acidosis so frequently associated with other diseases. For example, a patient might be more seriously threatened by an accompanying cardiac decompensation than the acidosis. Similarly in renal disease the accompanying acidosis might be the more serious condition. He felt that the general impression that cases of acid intoxication were necessarily fatal was not correct. He, personally, had seen two cases recover.

The Failing Heart; Recognition and Care of Certain Types.—Dr. HOWARD S. ANDERS of Philadelphia regarded the relation of the failing heart to heart failure as that of incipient tuberculosis to the advanced stage of the disease. He believed the failing heart to be almost invariably curable. One of the best danger signals of the condition was a ventricular flutter, palpable and audible near the apex beat and limited to the area bounded above by the third interspace and within by the left parasternal line. Intestinal autotoxemia he regarded as one of the most palpable causes of a heart that is failing functionally. Digestive disturbances with gastric and colonic distention and acidosis were also frequent elements in failing heart.

Dr. JAMES D. HEARD of Pittsburgh cited two cases demonstrating the inability at times to discover the underlying pathology in cardiac failure. The first case was an instance of auricular fibrillation in which autopsy showed a lesion of the sino-auricular node; the second, one of complete heart block without demonstrable causative organic lesion. Emphasis was given to the great prognostic value of early recognition of alternation of the pulse. The longest survival of any patient recorded was in a patient of Tabora who was alive six years after the arrhythmia was noted. Dr.

Heard regarded it as improbable that the majority of such patients would live more than a year.

The Curability of Certain Cases of Chronic Nephritis.—Dr. ALFRED STENGEL of Philadelphia discussed the question of chronic nephritis as a chronic condition, offering the proposition which he believed to be in keeping with the teaching of most pathologists, that chronic nephritis, like some other so-called chronic diseases, is not at all a chronic disease in the sense that it is a process which once initiated through the impetus originally given goes on and on as a progressive malady. Chronic arthritis, chronic myocarditis, and sclerosis of the liver were cited as not being in a strict sense chronic diseases in that they had inherent tendency to progressive deterioration as a result of the original impetus. They required for their increase a repetition of stimuli or of assault similar to the original one or the same as the original one. This he regarded as an important fundamental principle and defensible in regard to chronic nephritis. Evidence was submitted to show the relation of nephritis to infections and the probability that repeated reinfections occasion a gradually increasing involvement of the kidneys. Clinical evidence was cited as showing that removal of foci of infections is sometimes followed by an arrest of the disease, or, if not too far advanced, by complete disappearance of the evidences.

Dr. DAVIS RIESMAN of Philadelphia suggested the possibility of the over-emphasis at present of the subject of focal infection. This, however, was not entirely without merit, since subsequent to the over-emphasis, the little that was useful would remain. He believed that heredity was an etiological factor in nephritis and cited the case of a child dying from chronic parenchymatous nephritis. The father of the child had had chronic interstitial nephritis. He believed that the mistaken diagnosis of nephritis is sometimes given upon the discovery of albumen. A stone, while giving no classical symptoms, might be the focal cause of albumen and casts. Such had been proved to be the condition in a man who had been refused life insurance because of the urinary findings. In a boy of eight years of age regarded as a case of hopeless chronic nephritis perfect recovery followed removal of the tonsils, which apparently were the site of focal infection.

Dr. JAMES D. HEARD expressed his belief that the question of focal infection was not sufficiently considered in connection with the so-called degenerative conditions of kidney, heart, and blood vessels. Removal of sources of infection from the cardiac mechanism offered corroborative evidence of the influence of focal infection; a case in point was one of temporary fibrillary auricle in a diabetic patient in which upon the Allen treatment the urine became sugar free and the blood picture returned to normal.

Dr. GEORGE E. HOLTZAPPLE of York regarded the relationship between focal infection and chronic nephritis and other degenerative diseases so important and yet so apt to be overlooked that it should be continually emphasized. Carefully taken histories would frequently reveal evidence of chronic interstitial nephritis with but little to account for it beyond the presence of some infection, such as scarlet fever, in childhood. He emphasized the fact that focal infection might exist without local manifestation at the portal of entry and was discoverable only by the *x*-ray. Even when not found he was not unmindful that focal infection might exist.

Dr. HARRY M. KELLER of Hazleton agreed with Dr. Stengel concerning the relationship of focal infection of the teeth and tonsils to disease of the kidneys and other degenerative affections. The point confronting the general practitioner, however, was that of deciding when to pull out all the teeth of his patients, which decision might be rendered increasingly difficult by the opposing views of two or more *x*-ray specialists.

Dr. STENGEL, in closing, observed that nephritic patients were liable to local diseases, secondary to the nephritis and that a discovered focus might be the result of an existing nephritis rather than the cause of it. No harm could be done, however, in treating the lesion known to exist. Replying to Dr. Keller, it was obvious that sundry healthy teeth would have to seek that Valhalla where some of the appendices of surgical patients had found their place. Mistakes would be made by the over-enthusiastic and uninformed. He was not, however, addressing himself to that sort of practitioner, but calling attention rather to the importance of the proper investigation in all chronic diseases in which should be included nephritis.

Typhoid and Typhophors.—Dr. SAMUEL G. DIXON, Commissioner of Health of Pennsylvania, reviewed the work of the Bureau of Health in the prevention of typhoid fever and quoted its statistics of 3917 deaths from typhoid fever in 1906 and 1025 in 1915. There were reported in 1906 sick of typhoid fever 24,471; in 1915, the number was 8048. The name of typhophor was suggested as brief and distinctive for the "carrier" of typhoid fever. The history of a "carrier" was given who had been traced in an outbreak of typhoid fever in Perry County in the spring of last year. Under treatment with kaolin and autogenous vac. in the Hospital of the University of Pennsylvania in the service of Dr. Alfred Stengel the patient had regained her normal health. Emphasis was given to the importance of the protection of watersheds against pollution and possible carriers among construction and repair workers.

Dr. ALFRED STENGEL referred to the use of kaolin in the case under discussion as a beautiful illustration of the introduction of physical chemistry into medicine and surgery, the credit of which was due to the bacteriologists. After six negative cultures had been secured he had regarded the patient as *probably* cured. Three negative cultures required by some health boards he did not believe were adequate.

The Attitude of the Department of Labor and Industry Toward the Problem of Occupational Diseases.—Mr. JOHN PRICE JACKSON of the Department of Labor and Industry of Pennsylvania reviewed the results of the Workmen's Compensation Act since its inauguration on Jan. 1. and called attention to the proposed amendments of the law, notable the problem of what should constitute an occupational disease. He urged the importance of reports upon occupational diseases being forwarded to the department and of the holding of clinics of such diseases that the question might be adequately considered in the preparation of the proposed amendments. The profession was urged also to give thoughtful consideration to the proposed compulsory health insurance, and to its corrollary, old age insurance. Were such attention not given the possibility was mentioned of a resultant paternalistic and injurious governmental system.

Dr. J. W. SCHERESCHEWSKY of the United States Public Health Service called attention to inconsistencies arising in the general objection to industry bearing the economic loss due to certain forms of occupational disease. Such an instance was to be observed in the case of a man being suddenly overcome by benzol fumes while waterproofing a tank; in contrast to which a girl working in a cannery might become chronically poisoned by benzol fumes and death result. The only difference in the two cases would be the period of time in which death ensued. The inference was logical that if compensation were due in the first instance it was equally so in the second. Social insurance was to be regarded as the next most important social advance. Were the cost of such social insurance conditioned in a special locality or industry by the general prevalence of disease, obviously it would create a strong financial stimulus to preventive measures.

Dr. H. F. SMYTH of Philadelphia said that in defining an occupational disease there must be considered the patient's previous occupation, general health and physique, personal habits and home hygiene as well as the general hygiene of the plant where he was employed and precautions taken to minimize the particular hazard. To increase the number of compensable diseases full reports upon all occupational diseases he felt should be compulsory, such tabulation showing also the proportion of diseased to healthy individuals in the industry. He had had occasion to note the entire lack of such statistics throughout the United States.

Dr. JAMES I. JOHNSTON of Pittsburgh cited as illustrating complexities arising under the administration of the act the case of a coal miner who had had a fracture of the rib and in whom tuberculosis had become established. It was suggested as not improbable that the man had had tuberculosis and that his resistance to the disease had been lowered by the accident. How to settle the question equitably to all concerned offered some difficulties.

Dr. FRANCIS D. PATTERSON of the Department of Labor and Industry, in closing the discussion for Commissioner Jackson, urged that the medical profession of Pennsylvania formulate a definition of occupational disease which would stand an "acid test."

Some Phases of Chronic Colitis.—Dr. EDWIN ZUGSMITH of Pittsburgh considered the more common forms

of mucous and membranous colitis. Usually the discovery of mucus in the stools would establish the diagnosis. The amount of mucus varied from microscopic quantities to great masses constituting the entire discharge. Record had been made of a single evacuation of several pounds. The anemia and nervous irritability often present in colitis, the author stated, were frequently responsible for the diagnosis of neurasthenia. Pain, fatigue and meager endurance were mentioned as prominent features of the disease. Colitis was said to be often a secondary process resulting from infectious states of the gums and teeth and other focal infection. The relief of the bowel condition subsequent to the cure of pus was mentioned as an indication of the septic origin of colitis. In the absence of the pancreatic juice and bile or their diminution or alteration colitis was practically certain to follow. Ptosis, said by some to be invariably present in colitis, was considered a predisposing cause. The relationship of colitis and appendicitis was said to be very close, and special attention to the colon following appendectomy was advised. Colitis, while often a secondary process, might give rise to other conditions, such as neurasthenic symptoms and joint affections. Severe inflammatory rheumatism was considered as a frequent resultant of a diseased colon. Confusion in diagnosis was said to occur from absence of examination of the stools. The proximity of the hepatic flexure also caused confusion in diagnosis. Because of the widespread teaching that pain after eating indicated ulcer colitis was sometimes mistaken for ulcer of the stomach or duodenum. Such teaching Dr. Zugsmith regarded as fallacious. With proper food and under hygiene and medication many cases of colitis were cured, while most of the cases were helped to the point of complete comfort.

Dr. Samuel G. Gant of New York regarded colitis and constipation as much more frequently of rectal than of abdominal origin. He believed that such patients were often over-treated. Local treatment should be given in chronic ulcerative colitis, catarrhal or specific. The *x*-ray and the microscope he believed to be overrated, since in chronic ulceration and diarrhea diagnosis could be made by the symptoms, proctoscopic inspection of the rectum and microscopic examination of the stools. Care should be taken to see during irrigation that the medicament came in contact with all sides of the bowel. He advised as the best non-operative treatment the placing of the patient in the inverted position and filling the colon with about a quart of coal oil. Flushing of the colon with a solution of 20 grains of nitrate of silver and a quart of water would reduce the number of stools. Resultant pain was to be treated by washing out the colon with a saline solution. Such a patient should be placed upon a diet of baked potatoes and unsalted butter.

Dr. Lawrence Litchfield of Pittsburgh regarded the giving of too many enemas one of the commonest causes in the mild type of chronic colitis. He had found one of the heavier forms of liquid paraffin useful in the constipation, and has been particularly impressed with the association of chronic colitis and neurasthenia and hysterical conditions. In cases enteroptotic, congenital or acquired, he had seen the greatest benefit from a course of rest and feeding as suggested by William Gerry Morgan in Washington.

Dr. Zugsmith, in closing, said that the association of colitis with ptosis was so frequent that it was of necessity found in many patients who were nervous. This nervousness was increased by the absorption from the bowel with the consequent irritation; as these conditions improved the nervousness disappeared to a very great degree.

The Chemical Diagnosis of Gall-Bladder Disease.—Dr. Martin E. Rehfuss considered the diagnosis of gall-bladder disease, and particularly stone, from the standpoint of the examination of the blood serum for the cholesterol content, examination of the bile obtained by means of duodenal intubation, and the microchemical studies of the feces. Attention was directed to the importance of a definite increase of serum cholesterol in the causation of calculi. He had found in thirty cases of various conditions, sixteen being stone, a positive increase of serum cholesterol in every one. In the majority of another series of forty cases hypercholesteolemia was found. The importance of the microchemical examination of the feces was emphasized, inasmuch as gall-bladder and hepatic disturbances were, as a rule, accompanied by disturbances in fat digestion and in bile elimination.

The Diagnosis and Treatment of Chronic Intestinal Indigestion in Children.—Dr. Robert K. Rewalt of Williamsport emphasized the importance of recognition and treatment of this most frequent condition found in children to which too little attention was paid. The diagnosis was to be based upon the symptomatology which was rather comprehensive, and included irritability, capricious appetite, coated tongue, irregular fever, abdominal pain, tympanites and flatulence, constipation, poor physical condition, secondary anemia, indicanuria, and peculiar nervous phenomena. Treatment was to be based upon general management, strict diet with intelligent co-operation of mother and nurse, and drugs.

Dr. Harry Lowenburg of Philadelphia said it was not always possible to determine whether the digestive features present in these cases were primary, or the secondary effects of an underlying etiological factor. Such factor might be assumed to be a biochemical toxin which, interfering with the nervous mechanism of the gut prevented digestion and assimilation of food. It was also true that this toxin might be secondary to a disturbance of the digestive function as the result of prolonged injudicious feeding or of psychic shock incident to vicious environment. The non-digestion and subsequent fermentation, however, were dependent upon the character of food and the intestinal bacterial flora, and not upon the inherent defect in the gut. The term toxic diathesis in Dr. Lowenburg's opinion would better describe the condition discussed than chronic intestinal indigestion. Cases exhibiting irregular temperature extending over some time Dr. Lowenburg would attribute in all probability to chronically diseased caseous tonsils or to some other focus of suppuration in which case the digestive symptoms would be secondary. He would urge a systematic examination of the urine and of the stools in all of these cases. Diet was to be considered individually. In his experience the elimination of milk for a month or so was beneficial. Milk and scraped beef he believed to be incompatible, and he would substitute the term pancreatization for peptonization, being more comprehensive and self-explanatory. Evacuation of the bowels was better secured by the use of general measures, the local use of suppositories, glycerin and water enemas and the administration of toxic laxatives, than by purgation.

The Value of Roentgen Rays in the Diagnosis of Pulmonary Tuberculosis.—Dr. Willis F. Manges of Philadelphia presented this paper, and among the conclusions from his study the following are noted: That tubercles of macroscopic size, miliary or conglomerate, cast recognizable shadows on the sensitive plate; that the presence of tubercle shadows was essential to definite *x*-ray diagnosis, regardless of the variety, stage or extent of the lesion; that the lesion in the depth of the lung was as easily recognized as one at the surface; that in the acute exudative stage of bronchopneumonic phthisis the tubercle shadows might be obscured by the exudate shadows, and that there might be other cause of localized exudate than tuberculosis; that the roentgenogram frequently revealed tuberculosis overlooked clinically, and that in the Roentgen rays there was at hand a means of diagnosis as positive as the findings of tubercle bacilli in the sputum and available at a much earlier period in the disease.

Dr. George E. Pfahler of Philadelphia said that by means of well prepared stereoscopic plates the skilled roentgenologist could detect tubercles in the lungs when no larger than a pin head. In every case, however, there should be careful physical diagnosis as well as Roentgen study. The old idea that tuberculosis could not be definitely diagnosed until tubercle bacilli were found in the sputum must be abandoned in the interest of this class of patients. While a Roentgen study was valuable in all cases it was especially so in early and recurrent cases and in the chests of children. The difficulty in *x*-ray diagnosis of pulmonary disease, he said, was not so much in not detecting the disease as in determining its nature when recorded upon the photographic plate. Here even the most expert must still be in doubt upon certain points. By co-operation of physician and Roentgenologist, however, these points would be illuminated and a decided advance made in the diagnosis and treatment of pulmonary tuberculosis.

Dr. James I. Johnston of Pittsburgh emphasized the importance of supplementing the physical study of suspected tuberculosis with the *x*-ray plate. In the very early cases and in the determination of the activity of the lesion it would seem to an internist that the opportunity of the medical man were greater than that of the Roentgenologist.

Epidemiology and Clinical Features of Infantile

Paralysis.—Dr. Charles A. Fife of Philadelphia said that the epidemicity of infantile paralysis was first recognized in 1890. The disease had evidently been observed, however, by Underwood in 1774 and by Jork in 1816. While the theory of contagion by personal contact he said was supported by more evidence than any other he thought it probable that a specific carrier would be found. He regarded infantile paralysis as essentially a general infection in which the organisms and possibly toxins had a special affinity for the nervous system. Such a disease might cause innumerable combinations of signs and symptoms. The importance of the so-called abortive type and the preparalytic stage of the other types were emphasized in connection with public health considerations. Many children, he said, had developed paralysis some days after "an attack of indigestion" which might have been prevented by rest.

Dr. Alfred Hand, Jr., of Philadelphia described several widely varying cases of infantile paralysis which had been under his care. One was that of a man aged 48 who had sore throat, restlessness, inability to sleep, loss of appetite, with twitching of the muscles of the left side of the face. Bell's palsy of the left side of the face developed, and two days later paralysis of the right shoulder spreading to the leg. Unconsciousness and paralysis of the bladder and rectum followed, and death occurred in nine days. Sections of the medulla studied by Dr. Spiller showed lesions of acute anterior poliomyelitis.

Dr. Theodore H. Weisenburg of Philadelphia referred to his study of infantile paralysis from the neurological standpoint. Practically all deaths had been due to respiratory paralysis. The meningeal cases had been very numerous. In the meningeal cases there was in most instances marked increase of cerebrospinal fluid, although in one or two cases a dry tap had been obtained. He had seen a large number of bulbar cases; blindness, but once. He regarded lumbar puncture the best treatment, to be repeated as frequently as indicated. He was not enthusiastic concerning serum treatment; he believed that adrenalin offered a little more hope. He placed much emphasis upon the importance of rest.

Dr. Theodore LeBoutillier of Philadelphia believed the number of abortive cases of infantile paralysis in the present epidemic to be quite large. While he believed that the abortive type would give acquired immunity to a child for life, the case of one child had been observed who had an apparently authentic history of a second attack of the disease. In the transmission of the disease he was inclined to believe that dirt and dust, especially the latter, might be as great a carrier as direct or indirect contact. This was particularly emphasized to him in recalling that the rainfall during August in Philadelphia was .84 of an inch rather than the usual amount of 4½ inches. The mortality percentage also had been highest during August. In treatment lumbar puncture had been more effective than any other agent.

Some Phases of the Drug Habit Problem, Especially in Relation to the Harrison Act.—Dr. John H. W. Rhein of Philadelphia urged the enforcement of legislation in the control of the use of opium as a drug habit. The sale also of the hypodermic syringe should, in his opinion, be legally forbidden. The ill effects of the drug habit were said to be more apparent in character and psychic decline than in the physical deterioration. Treatment relative to the removal of the drug was given. A cold pack was of value for the nervous manifestations. The need of special wards in which these patients might be treated was emphasized. He believed it the duty of the State to care for drug addicts as for the insane, epileptic and feeble-minded. He believed that the distribution of habit forming drugs should be legally prohibited except legitimately by physicians.

(*To be continued.*)

A Certain Immunity of Arabs to Syphilis.—Sicard and Levy have noted the fact that wounded interned Arabs very often give positive seroreactions of syphilis, and especially the cerebrospinal-fluid reactions which point to localization in the nerve centers. The majority of those tested are by these criteria latent syphilitics. On the other hand, there is not the slightest clinical evidence of the disease. The nervous parenchyma, like the other tissues, is thus enabled to protect itself from the syphilitic virus, as are also the meninges. The only explanation of this phenomenon is racial immunity.—*Gaceta Médica Catalana.*

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS.

Twenty-Ninth Annual Meeting, Held at Indianapolis September 25, 26 and 27, 1916.

The President, Dr. Hugo O. Pantzer, Indianapolis, in the Chair.

(*Continued from page* 788.)

Prolapse of the Uterus in Nulliparous Women. — Dr. Palmer Findley of Omaha said that in several of the reported cases the procidentia occurred about the time of puberty and in these cases it was recorded that the girls were poorly nourished; some with tuberculosis of the lungs associated with persistent coughing, others who were compelled to do hard labor. A suggestion of the rarity of the lesion in the nulliparous women was found in the excellent contribution of Kepler, who collected 70 cases in the literature up to 1911. To this number he added one of his own and 80 from personal correspondence, making in all 151 cases of procidentia uteri in nulliparous women. He classified these cases as follows: (1) Cases due to congenital defects which occurred in the new born or at the time of puberty. (2) Cases not due to congenital defects, occurring later in life. In his judgment there was an element of infantilism in most if not all the cases of procidentia in nulliparous women. The fact that these women were sterile was highly suggestive. In support of the theory of infantilism as an underlying factor in the development of procidentia, he had two cases on record. The relation of mental defects to prolapsus uteri was forcibly illustrated by the observations of Kepler, who found 38 mental defectives in 80 cases of procidentia in nulliparous women. In this group were dementia precox, imbecility, idiocy, chronic mania, hysterical insanity, cretinism, and nervousness of high degree. It had long been recognized that defective mental and physical development went hand in hand and the casual relation of mental defects or prolapsus uteri was readily conceived.

Radium, a Palliative.—Dr. Douglas C. Moriarta of Saratoga Springs said that radium possessed a power to correct the disagreeable odor which accompanied the breaking down of cancerous tissue. This was a very great boon to the patient as well as to the household. Further, radium controlled hemorrhage. In six cases in which he used radium pain was relieved, the odor was markedly controlled, hemorrhage ceased, and there was a change in or a disappearance of the local pathological tissues. Two patients died in coma two months after the treatment; four were alive and hopeful. In one case the uterine hemorrhage was not of cancerous origin, but the condition was a terminal one. He was sure the patient would have died had it not been for radium. In using radium in these cases he believed it was possible to produce a toxemia which might prove fatal, and he was sure he had seen the end hastened in this way. He would suggest two precautions when applying radium locally; first, a patient with a low leucocyte count should not be given prolonged applications of radium and, second, when radium was used it should be accompanied by the liberal administration of alkalies. He wished to emphasize his conviction that no case of this type was so desperate, and no postoperative condition so hopeless that radium should not be used with an expectation of the alleviation of the distressing symptoms.

A Modified Gillian Operation and Its Ultimate Results. —Dr. Albert Goldspohn of Chicago said those who denied the pathological nature of retroversio-flexion affirmed it by their acts when they corrected it in connection with operations for its complications. The harm of retroversion was mostly brought about through embarrassment of the venous circulation by torsion of the broad ligaments and by traction in descent of the uterus. Clinical observation and experience indicated that the competency of the veins becomes impaired. Admitting this as a probable factor in the pathology, an effective and lasting as well as innocent cure was best obtained through an overcorrection, by suspending the uterus at a higher plane than it naturally or normally occupied, by a substantial implantation of round ligament loops, reinforced by their peritoneal covering, into the recti muscles and their aponeurosis, best after the Gillian technique, in addition to correction of the version. To secure the desirable degree of anteversion, and also to avoid intestinal complications, the implanta-

tion should not be more than 3 to 4 cm. from the edge of the symphysis pubis, and it should bring the distal unused segment of the ligament and its uterine origin both in contact with the abdominal wall. The efficiency of this modification of the Gillian operation was shown in the 127 examined cases, including the double test of pregnancy of 21, nearly all natural and mature births, with a return of displacement of only 1 3/5 per cent.; with both pelvic and general health "good" or "excellent" in 88 per cent.; improved in 10 1/5 per cent., and unimproved in only 1 3/5 per cent. in a total number of 164 cases observed from 2 to 7 years or over 3½ years on the average. Its harmlessness was shown by the utter absence of any deleterious effects at all traceable to it in the 21 births noted; likewise from the absence of intestinal complications and of discomfort to the patients.

Pathology of the Vulvovaginal Ducts and Glands.—Dr. JAMES E. DAVIS of Detroit gave the history of the literature of the vulvovaginal glands, with a short outline of the physiology, gross and microscopical anatomy. The special pathology as reviewed in the literature was at many points incomplete. The abundance of material for exhaustive study of these parts had been limited by clinical inattention to the details of the external genitalia examinations. A better definition of the gross pathology and frequent correlation with the microscopic changes in the ducts and glands was desired. The vulvovaginitis of school-girls, when of gonococcal origin, might exhibit remarkable chronicity. The unhealed lesions during puberty and adult life exhibited marked infectious potentialities with a much wider range of pathological changes than was commonly observed in cysts and abscesses. Primary malignancy, while not at all frequent, was significant and offered an unusual fatality when not recognized early.

The Standardization of Definite Procedures During Gynecological Operations.—Dr. E. A. WEISS of Pittsburgh said that his own deductions were that: (1) Many mistakes that were made during gynecological operations were preventable. (2) While the operator was legally responsible for every action in the operating room, the average surgeon did not take adequate measures to safeguard the patient and himself. (3) By adopting a definite routine or standardized method both for himself and his assistants, better team-work was accomplished, and consequently lessened mortality and morbidity.

The Surgical Treatment of Uterine Cancer.—Dr. J. H. JACOBSON of Toledo, Ohio, summarized as follows: The prophylaxis and especially the early diagnosis presented the greatest problem in dealing with uterine cancer. The radical abdominal operation thus far had given the highest percentage of cures in operable cases. Until radium, *x*-ray, and Percy's method shall have proved their superiority to operation, their use should be limited to the inoperable cases. There was abundant clinical evidence at hand to prove the value of radiotherapy; it therefore seemed logical to follow every palliative or radical operation with radiotherapy.

Practical Consideration of Surgery of the Stomach—Dr. GEORGE W. CRILE of Cleveland said that despite the mechanical perfection of operative technique, the first contact with the bad risk patient with gastric cancer was still menacing because of the narrow margin of safety due to starvation. In these cases the reserve alkalinity of the body had been reduced, nutrition was impaired and the reserve stores of water and of potential energy had been diminished. The purpose of his paper was to describe a plan of surgical treatment by which these dangerous factors might be obviated or diminished. As a result of these procedures in his clinic the mortality rate of operations upon the stomach, including explorations in cases of inoperable cancer, resections, and gastroenterostomies had been reduced approximately two-thirds.

The Mechanics of the Stomach After Gastroenterostomy.—Drs. J. H. JACOBSON and JOHN T. MURPHY of Toledo drew the following conclusions: "(1) That all patients examined in this series were uniformly well. (2) That gastroenterostomy openings properly made and placed do not obliterate. (3) That the gastroenterostomy openings functionate equally as well in the presence of either an open or closed pylorus. (4) That it is not necessary to artificially occlude the pylorus in gastroenterostomy. (5) That the gastroenterostomy opening to secure the maximum amount of drainage must be of ample size and placed as near the pylorus as possible, preferably in the antrum pylori. Such openings must not be made on the fundus of the stomach nor on the lesser curvature. (6) That gastroenterostomy is essentially a drainage operation. (7) That serious distention in the jejenum does not occur after gastroenterostomy; the food is seen to pass rapidly through the many loops of the small intestine before it finally stops. Even in those patients who are entirely relieved of their former symptoms food can be forced backward into the stomach from the jejenum and, although this can be done easily, such regurgitations do not seem to make any difference."

Value of Pain, Jaundice, and Tumor Mass in the Differential Diagnosis of Diseases of the Right Upper Quadrant of the Abdomen—Dr. J. D. S. DAVIS of Birmingham, Alabama, stated that the usual symptoms of peptic ulcer were pain, vomiting, and hemorrhage; the most important of which was pain. Pain was the earliest definite symptom. It was usually aggravated by large amounts of food and often relieved by small amounts. Pain might come on during ingestion of food, but more frequently came on a few hours after meals and at night. Gastric ulcers were often characterized by periods of long remission, intermittency taking place for long periods of time, during which the patient often believed himself well. The *x*-ray examination would often be helpful in determining the presence of peptic ulcer. Much valuable information might be secured by the roentgenologist, many of whom claimed to diagnose seventy-five per cent. of ulcers. In appendicitis the pain in a large number of cases occurred at the epigastrium and then was diffused over the abdomen and generally localized at or near McBurney's point. If the appendix was long enough to extend into the region of the gall-bladder and ducts its inflammation might excite symptoms of cholecystitis or choleodochitis and the pain might be at the rib border. If located behind the cecum pain might be referred to the loin or to the right rib margin. Jaundice was a valuable diagnostic sign. It appeared in appendicitis and renal disease only as a result of sepsis. Obstructive edema due to a duodenal ulcer near the ampulla of Vater sometimes resulted in a closure of the common bile duct and might cause pancreatitis and jaundice. Choledochitis and cholelithiasis was accompanied with slight or marked jaundice which might be of an intermittent or transient type. It might be so slight that an examination of the conjunctiva or a chemical examination of the urine was necessary to detect it. Appendical tumors might be located anywhere in the abdomen. It was sometimes six or more inches long and might become attached to any other abdominal organ. When inflamed it might become fixed by adhesions to some surrounding tissue. Floating kidney tumors were usually marked by smooth, sharp outlines and mobility. They were usually free from pain and tenderness unless obstruction resulted from ureteral pressure. A hydronephritic or pyonephritic kidney was usually stationary or fixed well back into the loin and did not move with the diaphragm. The hydronephritic kidney usually presented no urinary findings, while the pyonephritic kidney was usually accompanied by septic symptoms—the urine showing blood, pus, albumin, and casts. Pain was the most prominent symptom in all conditions of the right upper quadrant, and was of great value in a differential diagnosis, if the peculiarities and characteristics of pain common to each condition were kept in mind. Regardless of every aid in diagnosis, it was often difficult to differentiate and, instead of waiting months or years for the trouble to clear up, an exploratory diagnosis under nitrous oxide, gas-oxygen, or novocaine should be made.

Excessive Drainage Complicating Surgery Upon the Common Bile Duct.—Dr. J. E. SADLIER of Poughkeepsie, N. Y., said that in analyzing the histories of the two cases herewith reported, he noted certain points of similarity, namely, they both were long standing cases of common duct infection and incomplete obstruction; the latter was a result of the ducts being filled with gallstones to such a degree that they must have constituted an impediment to the normal and usual outflow of bile resulting from the obstruction, he had in each case well marked dilatation of the common duct. In only one case was there an alcoholic history and likewise in but one case was there involvement of the pancreas. Hence, these two conditions could be eliminated as complete causative factors. They could not be disregarded as partially influencing conditions in provoking the excessive drainage. He was unable to state the positive cause for this peculiar and serious complication, but he was disposed to be-

lieve that we had a condition somewhat analogous to that seen in the surgery of the hypertrophied prostate gland, where as a result of incomplete emptying of the urinary bladder, we got back pressure upon the ureters and kidneys, which, when suddenly relieved through operative intervention, resulted in an excess outflow of urine of low specific gravity, which was a well known source of danger in a person debilitated by long continuation of the pre-existing disease. Was it not quite probable that in partial obstruction to the outflow of the bile, by reason of the common duct obstruction from stone, we had a dilatation of the smaller biliary radicles in the liver? Increased back pressure, which, when suddenly relieved by operative removal of the obstruction, produced a condition of venous engorgement of the liver with resulting outflow of fluid which was more in the nature of a transudation than an actual biliary secretion, and this coupled with a back flow of pancreatic fluid through the dilated duct, would account for the excessive drainage. Yet he would not presume to definitely determine the causative factor, for the object of this paper was not to analyze the condition, but to suggest that in our operative work upon the common bile duct we must consider the possibility of excessive drainage and be prepared to combat it before the patient became dehydrated to the danger point.

Diverticulitis of the Descending and Pelvic Colon.—Dr. JOHN W. KEEFE of Providence, R. I., after reporting two cases in detail, emphasized the following points in connection with them: The symptoms found resembled those of appendicitis, but with the local manifestations on the left side. He pointed out the value of roentgenological examination, and also laid stress on the importance of differentiating diverticulitis of the colon from carcinoma, tuberculous or luetic growths. One should not attempt too much at the primary operation. The two-stage operation was often preferable. Temporary colostomy might be desirable. Conservative surgery was of the greatest value in this disease.

Appendicular Abscess, Complicated by Hemorrhage and Death.—Dr. MAGNUS A. TATE of Cincinnati spoke of this condition as rare. The patient was a young woman who had her first attack. Her abdomen was opened through the right rectus, and drainage was profuse for six days. At the end of the tenth and eleventh days her condition was good. On the twelfth day she complained of pain and nausea. On the morning of the thirteenth day there was hemorrhage from the wound, and on the fourteenth day her condition was alarming, death occurring the same evening. Autopsy revealed a gangrenous sac, the size of a dollar, which was found in the mesentery, probably the site of hemorrhage.

Inguinal Hernia Attached to the Cord, Undescended Testicle, Uterus, Tubes, and Broad Ligament.—Dr. EDMUND D. CLARK of Indianapolis reported a case which was a very good example of hermaphroditism in a man. The external conformation of the patient was that of a normal male. The hernial sac contained a uterus, broad ligament, and Fallopian tubes. Although married to an apparently normal woman for six years, no pregnancy had resulted.

Absence of Muscular Tone an Important Factor in the Etiology of Postoperative Paralytic Ileus.—Dr. R. R. HUGGINS of Pittsburgh stated that distention and stasis, varying in degree, followed most laparotomies. This was usually a temporary paralysis, a reflex action through the plexuses of Auerbach and Meissner, the result of manipulation and trauma. There were cases where infection could be excluded and patients died of paralytic ileus. The comparative frequency in vaginal hysterectomy was significant. There was little exposure and handling of intestines. Careful preoperative, operative and postoperative treatment was important in lessening postoperative paresis, but we were occasionally confronted with an aggravated form of this condition and death ensued. He believed that in certain instances, where death occurred from so-called paralytic ileus, it was primarily due to lack of muscular strength in the walls of the stomach and intestines. This depended largely upon the general muscular tone in the individual previous to operation, the amount of exhaustion incident to the operative procedure, and the effects of the anesthetic. Keith had called attention to the presence of nodal tissue, neuromuscular in character, in the bowels, which was similar to that in the heart. This was located at various points in the intestinal tract and acted as a local pacemaker. A block might occur, as in the heart, at any point where one rhythmical zone passed into another. Magnus demonstrated that the strips beat more actively when removed from a normally fed animal than from one that was not digesting. The intestinal tract had an intrinsic tone, which was regulated by extrinsic nerves. Tonic contraction and rhythmical peristalsis disappeared when there was general bodily weakness, and when the depleted central nervous system failed to deliver the necessary tonic impulses. Postoperative distention varied in direct proportion to the strength and tone of the general muscular system. Patients with poor general muscular tone required more careful preparation, and greater efforts to minimize exhaustion from anesthetic and operative effects.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, Held October 19, 1916.

THE PRESIDENT, DR. WALTER B. JAMES, IN THE CHAIR.

THIS meeting was devoted to the Wesley M. Carpenter Lecture and an appreciation of Dr. John B. Murphy.

Dr. WALTER B. JAMES, in opening the meeting, stated that the first Wesley M. Carpenter Lecture was delivered in 1892 and one had been delivered annually ever since. The lecturers had all been men who stood in the foremost rank of physicians and surgeons in the United States. In considering who should be selected to deliver the lecture this year Dr. Murphy had been chosen. He had accepted the invitation last spring and had intimated along what lines his paper would be. Dr. James said he heard nothing more from Dr. Murphy until August 9 when he received a letter telling him how much he had looked forward to coming, but stating that he had been overtaken by the disease to which he had devoted so much study, an acute metastatic aortitis. He died suddenly on August 11. On the forenoon of the day of his death, while suffering intensely and unable to speak, he wrote that he had placques in the aorta and requested that an autopsy be done to verify his diagnosis. This diagnosis was fully verified; it was found that he had acute, ulcerating placques in the aorta. He died as he had lived trying to help the medical profession in its task.

An appreciation of Dr. John B. Murphy.—Dr. GEORGE E. BREWER made this address. He said in part that on the 11th of last August the medical profession of America had been shocked by the sudden and unexpected news of Dr. Murphy's death. This news brought to all of them a sense of deep personal grief. It was fitting before listening to his last piece of scientific work that they should pay tribute to the memory of this remarkable man. Dr. Brewer then briefly reviewed the life and work of Dr. Murphy and enumerated the many honors that had been conferred upon him. He stated that early in his career Dr. Murphy had gone abroad to study and had been greatly impressed by the work of Billroth, Albert, and von Bergmann. At that time the scientific spirit in America had not been aroused. Dr. Murphy returned fired with enthusiasm and did much to give an impetus to scientific work in medicine and surgery in this country. He possessed all the elements of the successful surgeon, knowledge, originality, imagination, admirable technique, sober judgment untiring enery, and optimistic enthusiasm. He attacked by preference the great problem in surgery. By unwearying industry he opened the path and blazed the trail from one achievement to another. Among the first of his discoveries and one of the greatest contributions to modern surgery was the Murphy button. This was followed by his work on the problems of thoracic surgery in the broader sense; he saw conditions that had not come under the observation of other surgeons. In 1898, he gave the results of his observations in this field of surgery and to-day they still stood as surgical gospel on this subject. He then became interested in neurological surgery. It might be remembered that at this time a great deal of futile neurological surgical work was being done, because the anatomy and physiology of the nervous system were not understood. Dr. Murphy devoted two years to the study of the anatomy and physiology of the nervous system. The work that he did in this field was not appreciated at that time, but it was to-day. He next attacked the problem of ankylosed joints. Up to this time, as a rule, these patients passed from one surgeon to another without receiving any benefit. When Dr. Murphy announced the results that he had obtained in apparently hopelessly ankylosed

joints and showed that these joints could be returned to normal function the profession was astounded. Following this came his familiar work in bone grafting and now, to-night, his work on septic arthritis. Those were but a few of the contributions Dr. Murphy gave to surgery which marked distinct advances. In all of these he departed far from the beaten track. He valued the advantages of animal experimentation and of laboratory investigation. Every operative procedure was first tried on animals; he never experimented on his patients, but always kept uppermost in his mind the welfare of those who entrusted their lives to his care. As a teacher he was no less great than as a surgeon. His pupils looked upon him as a great master of surgery. In teaching the profession at large he was equally as successful as in undergraduate work. He was not only a master in surgical technique, but a clear and logical thinker, and a powerful and interesting debater on medical subjects. He was quick and alert physically and even more so in his mental processes. He despised sham, hypocrisy, indolence, and all low standards of living. He lived his religion in his daily life. He was a fair man alike to friend and enemy. In closing, Dr. Brewer said it might be well to ask what lessons might be learned from the contemplation of this singularly gifted man. His life work refuted what was held by many in the profession, that was, that if one wanted to succeed in his profession in the community in which he lived and to become a great surgeon, he should not waste too much time in purely scientific or laboratory work. Dr. Murphy made his great contributions to surgery because he was willing to devote a large measure of time to laborious, painstaking work in the laboratory. Dr. Murphy was revered for his qualities of mind and heart and his devotion to duty, and also for the results of his achievements that made it possible to give relief to suffering humanity.

Wesley M. Carpenter Lecture—A Clinical and Experimental Study of the Metastatic Arthritides.—Dr. PHILIP H. KREUSCHER of Chicago delivered this lecture which was based on the study of over 800 clinical cases and was illustrated with lantern slides. He stated that on the last page of his day book Dr. Murphy had written the following quotation: "He went away as he had come, nobly careless of himself, thinking only of the things he had tried to do." Dr. Murphy's work had been splendidly conceived and it was with reluctance and a recognition of his great responsibility as well as his great privilege that the speaker brought the message committed to him.

Coming to the subject of the paper, he said that by metastatic infection was meant an infection in or about joints due to the invasion of pathogenic organisms which had been harbored and were capable of multiplying in the tissues of the host. They were classified as acute, subacute, and chronic; as uniarticular, biarticular, and multiarticular. Etiologically they were classified as those due to a known organism and those in which the origin could not be found. Pathologically they recognized acute or chronic serous, chronic suppurative, and fibrinous or plastic arthritis. They did not include those due to tuberculosis or the bone involvements of syphilis. Particular stress was laid on the following points: "(1) Every case of acute general infection is surgical and must be treated surgically. (2) Those lesions thought to be infections in the joint cavities are in reality infections about the joints, outside of the joint cavity. (3) There is a definite incubation period for every metastatis arthritis. (4) The joint fluid does not contain bacteria in a large percentage of the cases. (5) Metastases to the joints occur because of a definite logical reason." To appreciate the many problems, mechanical and pathological and the management of infection, one should recall the anatomy of the synovial membrane with its layers, pockets, and diverticula, and the blood supply of the joints. One must consider the specific, exciting, and predisposing causes as well as the atria of infection. An analysis of 849 cases showed that the source had occurred in the following sites and with the frequency designated: In the tonsils in 25.5 per cent. of the cases; the teeth, 18 per cent.; urethra, 17 per cent.; sinuses, 17 per cent.; lungs and bronchi, 5 per cent.; bladder, 4 per cent.; kidney pelvis, 4 per cent.; appendix, 2 per cent.; gall-bladder, 2 per cent.; furunculosis, typhoid fever, scarlet fever, tetanus, and dysentery, each 6 per cent. The following organisms were found: The streptococcus in 31 per cent. of the cases, gonococcus, 14 per cent.; staphylococcus, 8 per ent.; colon bacillus, 4 per cent, and a combination of two or more organisms in 38 per cent. of the cases. The infection was uniarticular in 9 per cent. of the cases; biarticular in 13 per cent., and multiarticular in 78 per cent. It was acute in 13 per cent., subacute in 21 per cent., and chronic in 66 per cent. Both extremities and the spine were involved in 73 per cent. of the cases. Seventy-five per cent. of the general infections occurred between the ages of 10 and 40 years, and 11 per cent. from 50 to 80 years. The greatest susceptibility was between the ages of 30 and 40 years. In this series approximately 60 per cent. were females. Three-fourths of the infections occurred during the late fall, winter, and early spring. There was a definite history of trauma in 90 per cent. of the cases. Ankylosis occurred in practically 4 per cent. of the cases. The total of those who were partially incapacitated was 85 per cent., and there were only 15 per cent. that could continue to do their customary work without any interference with function. There was a definite period of incubation for every infection. For the Neisserian infection it was 18 to 24 days after the primary infection; for the staphylococcus 8 to 14 days, while a streptococcus infection might occur within 48 hours. In typhoid fever the secondary infection might occur four, six, or eight weeks after the beginning of the typhoid. The diagnosis was not complete until one had determined the atrium of the infection. This was sometimes easy, as when there was a definite history of tonsilitis, but in other cases it might be very difficult to trace a connection between a metastatic infection and the original infection. One could not make a diagnosis from the fluid taken from a joint. In the last 37 consecutive cases which they had examined only one showed a positive bacterial growth on the cover; this was in a series of untreated cases and included every kind of infection; several were uniarticular and several multiarticular. Dr. Kreutscher said he could not understand why certain authors reported positive cultures from the joint fluids in from 5 to 87 per cent. of their cases. Dr. Murphy and he believed that the infection was periarticular and that only in rare instances did bacteria pass directly into the joint cavity. Three cases of hypertrophic villous synovitis all gave negative bacterial findings. The reason for the absence of bacteria from the fluid of the joints was explained by assuming that the bacteria were carried by the blood stream and lymph channels. There were important arterial anastomoses surrounding the large articulations. The diaphysis and epiphysis were supplied by the larger vessels, branches of which passed around these structures, passing inward to the ends of the bones, to the perichondrium, and the synovial membrane. The synovial membrane and fringes were supplied with a rich network of capillaries from smaller synovial branches. Dr. Murphy, in 1912, expressed the opinion that the infecting microorganisms found lodgment in the terminal loops of these synovial branches, but did not ordinarily penetrate to the synovial fluid.

The treatment of metastatic arthritis was surgical. Arthritis no more belonged to the domain of internal medicine than did acute fulminating appendicitis. Treatment by internal medication and external applications was as irrational as the same treatment applied to a perforating gastric ulcer. One must put into effect masterly, preconceived, accurately directed and timely activity. Such treatment consisted first in aspiration. Drainage tubes were to be condemned. They were the cause of ankylosis in 96 per cent. of the cases in which they were employed. Second, a Buck's extension must be applied the first day in every case of acute arthritis. The patients found this apparatus comfortable and wore it at night. It gave relief by removing the intraarticular pressure. Third, cofferdamming of the infiltration of the lymph spaces must be accomplished by injecting an antiseptic solution into the joint. Fourth, the primary focus of infection must be removed if it could be found, whether it was in the tonsils, the teeth, the nasal sinuses, or the gastrointestinal tract. Fifth, deformities should be treated by extension, the Travois splint, plaster casts, and other appliances. Sixth, autogenous vaccines were of great value if used for the lesions for which they were intended. They should be made from the bacteria grown from the patient's blood in accordance with recognized and approved methods. Seventh, in the way of prevention, it was the duty of every physician to advise his patients in regard to the danger arising from a focus of infection in the teeth, the tonsils, or elsewhere in the body.

Dr. Kreuscher said that during the course of this study many problems had come up and five of these had

been the subject of investigation. These were as follows: (1) Experiments to determine the intraarticular pressure resistance of human joints. (2) Experiments to find a suitable antiseptic for joint injections. (3) Investigations to determine the localization of pathogenic organisms following the injection of bacteria into the blood stream of rabbits, and to find out why they did not pass directly into the joint fluid. (4) An endeavor to find out why metastases occurred. (5) An investigation to find out whether the rapidity of metastasis depended upon the type of organism or upon the variety and virulence of the mixed infection. It was shown that the capsule of the adult hip would withstand a pressure of from 35 to 50 pounds per square inch; the capsular ligament of the adult knee in the cadaver would withstand 60 to 120 pounds pressure per square inch before rupturing. It was noted that when an inactive joint was subjected to severe internal pressure, the leg tended to become slightly rotated inward, and adducted and flexed, as in acute infection with effusion. A large number of experiments were made with a variety of antiseptics from which it was found that a solution of 2 per cent. formalin in glycerin, which had been made twenty-four hours before using, was most effective. From their experiments to determine the localization of pathogenic organisms following their injection into the free blood stream, they had concluded that the bacteria localized in the terminal loops of the synovial branches and did not enter the joint fluid. Among experiments made along this line, *B. pyocyaneus* from postoperative wounds were injected into rabbits, the dose being two billion bacteria. All of these rabbits died at the end of four days without joint manifestations. Cultures were taken from the heart blood of these animals and the *B. pyocyaneus* was present in pure culture. Two billion bacteria were then taken from the cultures of the heart blood of these rabbits and injected into the ear veins of a new series of rabbits and these died in eighteen hours. A third series of rabbits were injected with a smaller dose of the bacteria, and some of these were sick for several days and recovered; others showed no illness at all. They had concluded from this that the *B. pyocyaneus*, usually considered a low-grade pathogenic organism, might cause death quite as quickly as the streptococcus and occasionally might cause joint involvement. Experiments were made with hemolytic streptococci by injecting two billion bacteria in the ear veins of rabbits. Some of the rabbits died in twenty-four hours, others recovered after twenty-seven days, having shown positive joint manifestations on the fourth and fifth days. Sixty-five per cent. of the animals showed involvement of one or more joints; 4 per cent. showed suspicious joint lesions, and 30.5 per cent. showed no involvement up to date. In 4 per cent. of the animals the joint localization did not take place until the fifteenth day after the injection. At autopsy a smaller percentage of joints than was expected were found free from pus containing bacteria. In a larger percentage than was expected abscesses occurred around the joints and along the shafts of the bones in the soft tissues. They therefore concluded that a metastatic infection in a large percentage of the cases occurred outside the joint, a conclusion Dr. Murphy reached a number of years ago. There was a definite reason for the occurrence of metastases. A metastasis did not usually take place unless there was a mixed infection or a secondary infection was superimposed on a primary one. A metastasis from a strepococcic pyorrhea alveolaris did not usually take place until a foreign streptococcus was superimposed on the primary infection. Experimentally they had found that a guinea pig did not ordinarily show metastases in the distal organs even after large quantities of microorganisms had been injected directly into the heart, but if these injections were preceded or followed by an injection of organisms of another strain, metastases occurred in the liver, kidneys, endocardium and joints. Rabbits injected with streptococci and then with a quantity of staphylococci, or other pathogenic organisms, showed a rapid and multiple joint infection in 90 per cent. of the cases. The lesson to be learned from this was that if they were going to prevent metastases it would have to be done by the early removal of the focus of infection. The laity would have to be taught that if this were not done the condition might become chronic and metastases and deformity might follow. When this occurred they would have to resort to arthroplastic treatment of the kind Dr. Murphy had devised and carried out with such success. The fifth problem proposed, namely, did the rapidity of metastases depend upon the specific infectious organism, or did it depend upon the variety and virulence of the mixed infection, they were still working upon, but as yet had not reached definite conclusions.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

Kentucky State Medical Board.

June 13, 14, 15, 1916.

(*Continued from page* 750.)

SURGERY.

1. (*a*) Differentiate between hydrocele, scrotal hernia, and varicocele. (*b*) What treatment would you advise in each?
2. How would you treat a compound, comminuted fracture of the olecranon process?
3. (*a*) Differentiate between fracture of the vault and base of the skull. (*b*) What treatment would you advise in each?
4. (*a*) How would you diagnose an hypertrophied prostate gland? (*b*) What treatment would you advise?
5. Differentiate between intestinal obstruction, acute appendicitis and tubercular peritonitis.

PATHOLOGY.

1. (*a*) Describe healing by granulation. (*b*) To what conditions does it lead?
2. Give the pathology of a gangrenous, perforated gall-bladder.
3. (*a*) Describe the gross appearance in pyosalpinx, and (*b*) what is the usual infecting organism?
4. Name and describe three varieties of malignant tumors.
5. (*a*) Describe bone necrosis. (*b*) What is a sequestrum. (*c*) An involucrum?

SKIN, HYGIENE, MEDICAL JURISPRUDENCE, MENTAL AND NERVOUS DISEASES.

1. Discuss and diagnose lupus vulgaris.
2. Discuss and diagnose psoriasis.
3. Name the varieties of eczema.
4. What are the conditions necessary for a model sleeping room?
5. Give special hygienic conditions required for factories in which women and children are employed.
6. What would you say as to the fitness of water for drinking purposes which contains nitrites and nitrates?
7. (*a*) Name as many nuisances dangerous to health as you can which are frequently found about cities. (*b*) About country homes.
8. What principal measure would you use to prevent the spread of the infectious diseases?
9. (*a*) What medico-legal complications might arise due to an erroneous diagnosis of pregnancy? (*b*) How would you avoid them?
10. Give the etiology of multiple neuritis.

OPHTHALMOLOGY, OTOLOGY, AND LARYNGOLOGY.

1. Give some of the conditions that would cause you to advise iridectomy.
2. (*a*) What is a staphyloma? (*b*) Give cause.
3. Give cause and symptoms of chronic dacryocystitis.
4. (*a*) Diagnose a case of empyema of frontal sinus. (*b*) How would you manage it?
5. (*a*) Define aphonia. (*b*) Give some of its causes.
6. Give etiology and symptoms of hyperemia of the labyrinth.
7. (*a*) What are the usual causes of rupture of the membrana tympani? (*b*) What symptoms would you expect to follow?
8. What symptoms would lead you to make a diagnosis of acute circumscribed otitis?
9. What are the symptoms of postnasal adenoids? (*b*) What means would you employ for relief?
10. (*a*) Under what conditions would you intubate? (*b*) Give detailed technique.

ANSWERS.

SURGERY.

1. In *hydrocele* the tumor begins in the scrotum and may ascend to the inguinal region; does not vary very

much in size, except to steadily increase; is translucent; is dull on percussion; gives no impulse on coughing.

In *hernia* the tumor begins in the inguinal region and may descend to the scrotum; is very variable in size, and may be reducible, or disappear on lying down; is not translucent; is not dull on percussion; gives an impulse on coughing as a rule.

In *varicocele* the swelling feels like a bag of worms; it may empty when the patient lies down; there is an impulse on coughing or straining, but no translucency.

Treatment of hydrocele.—The fluid may be withdrawn with trocar and cannula; this will have to be repeated.

Tapping, followed by injection of strong antiseptics, such as carbolic acid, or iodine. The sac may be excised either wholly or partially.

For *hernia*, Bassini's operation (or some modification of it) is recommended.

For *varicocele* the best treatment is to remove the varicose veins between double ligatures.

2. *In compound comminuted fracture of the olecranon process* "the wound should be irrigated with a few gallons of physiological sterile salt solution, and the edges of the wound trimmed of devitalized tissue. Internal fixation of the fragments should not be performed at the initial operation in compound cases, though it may be possible to retain the fragments in position by suturing the fascia covering the posterior surface of the process in closing the wound. A secondary operation may be done after the wound (rendering the condition compound) has healed, and the danger of infection has passed. Following a firm internal fixation of the fragments the upper extremity may be immobilized with an internal right angle splint." (Preston's *Fractures and Dislocations.*)

3. FRACTURE OF BASE OF THE SKULL. The *Signs* are those of (1) injury to the brain, (2) escape of cranial contents, (3) injury of cranial nerves. (1) *Injury to the brain* may be of the nature of concussion, compression, or laceration. (2) *Escape of cranial contents*, which may be blood, cerebrospinal fluid, or rarely brain itself. 1. *Hemorrhage* manifests itself in various situations, according to the position of the fracture. In the *anterior fossa* the bleeding may be from the nose or into the orbit, or may pass back into the pharynx, be swallowed, and subsequently vomited. The eye may be pushed forward and pulsate if the cavernous sinus be ruptured. In the *middle fossa* blood usually runs from the ears; but slight bleeding from the ear may be caused by minor injuries, such as rupture of the membrana tympani, tearing of the lining of the auditory canal, and fracture of the tympanic bone. In the *posterior fossa* a hematoma may form behind the mastoid process. 2. The escape of *cerebrospinal fluid* is a certain sign that a fracture communicates with the subdural space. It may appear in the same situations as hemorrhage, but is usually found escaping from the ear owing to fracture of the petrous bone. The fluid is limpid, specific gravity 1005, with no albumin, but containing pyrocatechin, which gives the same reaction as sugar with Fehling's solution. The amount which escapes may be small or very large, but as a rule it soon ceases. (3) *Injuries to the cranial nerves vary* according to the site of fracture. That most commonly involved is the facial, in the aqueductus Fallopii, and the paralysis may come on immediately from rupture, or after two or three weeks from the pressure of callus.

Treatment: The chief aim of treatment is to prevent sepsis. The ear must be mopped out with an antiseptic, and then kept covered with an antiseptic dressing, as if it were a wound. The patient must then be kept quiet, the bowels opened with a purge, and an icebag applied to the head. The diet should be low, and a return to active life not permitted for six weeks. If septic meningitis occurs the patient is bound to die. (From *Aids to Surgery.*)

Fissured fractures of the vault are due to direct injuries, such as blows, or to indirect injury, such as compression, which bursts the skull. If simple there are no definite signs; if compound the fissure can be seen and felt. The prevention of sepsis forms the main line of treatment. Callus may form at the site of fracture and produce traumatic epilepsy.

Depressed and punctured fractures are due to direct violence; usually affect the vault; may be simple, compound, or comminuted. The outer table may be depressed without the inner being broken, in such places as the frontal sinus. Rarely the inner table is broken and depressed without fracture of the outer. As a rule both tables are broken. The inner suffers most damage, as it is less supported; the force of the blow is more diffused by the time it reaches the inner; also the momentum of the striking body is less, and the débris of the outer table increases the size of the penetrating body.

Symptoms: If there is a wound, the fracture and depression may be seen, and blood, cerebrospinal fluid, or brain, may be escaping. If there is no wound a careful examination is necessary, as a hematoma may form and obscure the depression. In cases of doubt an incision should be made.

In a *simple depressed fracture* there is usually some concussion, which is followed by compression from hemorrhage in the neighborhood. The depressed bone also causes compression later by the *spreading edema* it sets up in the brain. Death may result quickly, or the patient may recover and then become the subject of traumatic epilepsy from irritation of the cortex. If the depression is over the motor area convulsions or paralysis are quickly induced.

In a *compound depressed fracture* the blood escapes and does not produce compression. Concussion may or may not be present. The advent of sepsis produces inflammation of the bone, membranes, and brain, which may be limited if the drainage is free; but if not death soon follows from compression by the inflammatory exudation. During the stage of compression a hernia cerebri is formed. If the depressed fragments are early removed and asepsis is maintained the patient has a good chance, unless the brain itself is severely injured

Treatment.—In all cases, except the saucer-like depressions which occur in young infants, it is necessary to elevate or remove the depressed fragments, stop all bleeding, and disinfect the wound. Symptoms should never be waited for, because, although the patient may recover without operation, the depressed bone may cause traumatic epilepsy or insanity. The skin is shaved and purified, and a large flap is turned down to expose the fractured area, or if a wound is present it is enlarged. Comminuted fragments are removed, and sharp edges which press on the dura mater are clipped away with Hoffmann's forceps. If an elevator cannot be introduced under the depressed bone a trephine hole is made through the nearest sound bone, the elevator introduced, and the bone prised up. The piece of bone removed with the trephine should be replaced. If the dura mater is torn it should be stitched up and then the scalp flap is sutured without a drain, unless oozing is still going on. If the fracture has been compound it is better to drain it for twenty-four hours. In punctured fractures the hole must be enlarged by trephining, so as to remove the depressed spicules. After operation the patient must be kept quiet in a darkened room on liquid diet for a few days.—(*Aids to Surgery.*)

4. *Prostatic hypertrophy is characterized by:* Slowness in starting urination; difficult micturition; frequency of micturition, particularly at night; the presence of residual urine, as may be demonstrated by catheterizing the patient just after he has urinated; dull, aching pain in the perineum and above the pubes; enlargement of the lateral lobes of the prostate; there may be cystitis and retention of urine. *Palliative treatment* consists in: Mild and unirritating diet, avoidance of alcohol, taking plenty of milk or water, or other diluent. Alkalies and sedatives should be taken, also urotropin or other antiseptic so as to prevent cystitis. Regular catheterization, at least once a day, preferably in the evening, and with due aseptic precautions. *Operative treatment* is excision of the prostate gland.

5. *Acute appendicitis.*—The recognition of a typical case depends upon a few cardinal symptoms—viz., the acute development of severe pain in the right iliac fossa, coming on in a person previously healthy and usually under forty years of age; appendicular tenderness, unilateral induration, fever, vomiting and constipation, or, more rarely, diarrhea.

Acute tuberculous peritonitis.—As in appendicitis, so in tuberculous peritonitis, pain, tenderness, and fever are present, but in the latter the onset is more gradual, and the signs of tumor and increased resistance in the ileocecal region are absent. Movable dulness may be present in the tuberculous affection, but not in appendicitis until the peritonitis is general. The lungs generally show lesions in tuberculous peritonitis.

Acute intestinal obstruction.—When this is due to intussusception there may be signs of a tumor, but not at McBurney's point; the tenderness over the site of the mass is less intense, while the frequent bloody discharges that are seen in this condition, accompanied by tenesmus, do not characterize appendicitis. When obstruction is caused by strangulation stercoraceous vom-

iting is apt to occur; pain, local tenderness, and signs of a tumor appear, but not at McBurney's point. (Anders' *Practice of Medicine.*)

PATHOLOGY.

1. (*a*) *Healing by granulation* occurs (1) when the edges of the wound have not been brought together, (2) when the edges have been so damaged that sloughing occurs, (3) when sepsis has prevented healing by first intention. Exudation of plasma and leucocytes occurs, followed by fibroblasts and budding from the capillaries, thus forming granulation tissue. The dead tissues or sloughs are separated, and a red area of granulation is then exposed. The deeper layer of granulation tissue is converted into fibrocicatricial tissue, which contracts, and so the wound gradually lessens in size. In the meantime epithelium spreads in from the edge over the surface, and so the scar is completed.—(*Aids to Surgery.*)

(*b*) It leads to cicatrization.

2. *Pathology of gangrenous perforated gall-bladder.*—Should the gall-bladder have been previously normal or only slightly diseased and non-adherent it may become considerably, sometimes very much, enlarged; but if previously the seat of cicatrization from chronic inflammation no enlargement may occur; in this case it is usually united to adjacent tissues and organs by adhesions. The wall of the gall-bladder is softened, swollen, edematous, congested, and usually very dark reddish, greenish, or blackish in color. The mucosa is congested and desquamated and covered with a fibrinopurulent, sometimes also hemorrhagic, exudation. In many cases there is more or less ulceration, especially toward the fundus in consequence of the relatively poorer vascular supply of the fundus and the gravitation of gallstones. The ulceration may proceed through the wall and lead to perforation. The cystic duct is usually occluded even in the absence of gallstones. The contents consist of turbid, bile-stained, fibrinopurulent, sometimes sanguinolent fluid; gallstones are present in about 80 per cent. . . . The infiltration of the gall-bladder is widespread and may lead to extensive dissection of the different coats, the separation, for instance, of the mucosa from the underlying coats or extensive sloughing. . . . When a large section of the gall-bladder becomes necrotic the term gangrenous cholecystitis is not inaptly applied. The lesions resemble those just described, with the addition of complete necrosis or gangrene of a variable portion of the gall-bladder; the gangrene usually begins at or near the fundus and spreads toward the neck; in some cases it begins about a gallstone more or less firmly embedded in the wall of the gall-bladder.—(From *Modern Medicine*, by Osler and McCrae.)

3. *Pyosalpinx.*—"The dilation of the tube into a cyst is the final stage of salpingitis. The tumor formed by a dilated tube is seldom larger than a pear, although a pyosalpinx may reach to the umbilicus. The tube is commonly contorted, winding round the upper and back part of the ovary, the outer part of the tube being the more dilated. The wall is generally thickened, but at one or more spots it may be thinned. The thinning is not due to tension, but to ulceration, and this ulceration may take place at a part where the tube is not dilated, and may perforate and cause death. The mucous membrane is overgrown, thickened, edematous, injected so as to be purple in color, and ecchymosed, or it may be slate colored; there may be calcareous plates and nodules in the mucous membrane. In some cases there has been overgrowth of gland tissue. The ovary is generally enlarged."—(Herman's *Handbook of Gynecology.*)

The usual infecting organism is the gonococcus.

4. A *sarcoma* is a malignant connective tissue tumor; the others are all innocent. A sarcoma consists of cells, between each of which a minute quantity of intercellular tissue can be demonstrated. The cells differ in size and shape in different growths. Bone and cartilage may be developed in any of them. It is always developed from mesoblastic tissue; it may be at first defined or encapsuled, but always in its later stages infiltrates the surrounding tissues. The blood supply is always abundant, even to producing a pulsating tumor. The vessels are only clefts between the cells of the growth, so that interstitial hemorrhage is frequent, and dissemination by the veins is rendered easy. It follows from this that secondary growths occur first in the lungs, unless the primary growth is in the portal area. Other organs may be affected after the lungs. Occasionally lymphatic glands are implicated, especially in melanotic sarcoma, lympho-sarcoma, sarcoma of tonsil, testis, and thyroid. Secondary changes, such as myxomatous, fatty and hemorrhagic, may occur. A sarcoma when cut appears homogeneous and varies according to its vascularity from the grayish-white of a fibrosarcoma to the deep maroon of a myeloid sarcoma. Sarcoma may be congenital or appear at any age. The species are determined according to the prevailing type of cell.

Rodent ulcer is a carcinoma beginning in sebaceous glands. It generally occurs in patients over forty and is of very slow growth. It begins as a smooth, rounded knob in the skin about the nose, eyelids, orbital angles or cheeks, slowly increasing in size. In time ulceration occurs. The ulcer has a smooth, depressed base covered with ill-formed granulations and bounded by a slightly raised, indurated, rolled over edge. There is little discharge if sepsis is prevented and little or no pain. The lymphatic vessels and glands are not affected, and dissemination does not occur. The ulcer spreads and destroys surrounding structures; even bone is not spared, so that the brain may ultimately be exposed.

Epithelioma, or squamous-celled carcinoma, may arise on any surface covered with stratified epithelium. It usually arises in the middle aged or elderly, but may also occur in the young. It often results from long continued irritation and may arise in old scars or ulcers. It may appear in one of three forms: (1) A wartlike growth with an indurated base; (2) a small circular ulcer with raised, rampartlike edges; (3) an indurated fissure. The growth extends to the deeper structures; the surface ulcerates and becomes foul from contamination with putrefactive organisms. The nearest lymphatic glands always become infected sooner or later, and a fatal termination occurs rapidly unless treatment is early and thorough. Secondary deposits, except in the glands, are rarer than in glandular carcinoma. The glands sometimes undergo cystic change, invade the skin, ulcerate, become foul, and may cause death by secondary hemorrhage from ulceration into large blood vessels.—(*Aids to Surgery.*)

5. "*Necrosis*, or gangrene of bone, is death of a portion of bone *en masse*. The dead portion (*sequestrum*) varies in size from a small superficial flake, such as follows suppurative periostitis, to a mass representing the entire shaft of the bone, such as not infrequently follows acute osteomyelitis. The causes are acute and chronic inflammations of the periosteum, bone and medulla. The *sequestrum* separates from the living bone by a line of ulceration or demarcation much the same as in gangrene of soft parts. The surrounding living bone usually undergoes a condensing ostitis and becomes much harder than normal. Small and superficial sequestra may be discharged spontaneously through a sinus, which inevitably exists in all but very small aseptic sequestra, in which complete absorption without suppuration is possible. If the necrotic mass is large or centrally located spontaneous discharge is impossible and suppurative inflammation may continue for years. The dense bone which surrounds the sequestrum in these cases is called the *involucrum*, and the sinus leading from the surface down to the cavity in which the sequestrum lies is called the *cloaca*."—(Stewart's *Surgery.*)

SKIN, HYGIENE, MEDICAL JURISPRUDENCE, MENTAL AND NERVOUS DISEASES.

1. *Lupus vulgaris* is a tuberculous cellular new growth, characterized by reddish or brownish patches consisting of papules, nodules, and flat infiltrations, usually terminating in ulceration and scarring. The affection occurs most often upon the face and is due to local infection by the tubercle bacillus. It is distinguished from syphilis and epithelioma by its occurrence before puberty, slow course, history and concomitant signs of the tuberculous diathesis, soft nodules, multiple and superficial ulcers, absence of pain, yellowish, shrunken and hard scars and slight discharge. The condition is chronic and in small patches may be entirely cured.—(*Pocket Cyclopedia.*)

2. *Psoriasis* is a common chronic inflammatory disease of the skin, characterized by variously sized lesions, having red bases, covered with white scales resembling mother of pearl. It affects by preference the extensor surface of the body. The lesions are infiltrated, elevated, clearly defined, covered with white, shining, easily detachable scales which, upon removal, reveal a red, punctate, bleeding surface. The eruption is absolutely dry, and itching is usually absent.—(*Pocket Cyclopedia.*)

The special points of value in reference to diagnosis are the lesions of variable dimensions, all being capped

with pearly white scales; borders severely outlined; tendency to convalescence, with the presentation of bleeding points upon removal of scale.

3. *Varieties of eczema.*—Eczema erythematosum, E. papulosum, E. vesiculosum, E. pustulosum, E. rubrum, E. squamosum, E. fissum, E. sclerosum, E. verrucosum, E. papillomatosum.

4. The sleeping room should be as large as possible, with the maximum of sunshine and fresh air; it should face the south, or east, or southeast, and should contain no hangings and have as few "dust catching" contrivances as possible; it should not lead into a bathroom. There should be a separate bed for each person, and, preferably, each person should have his own room. There should be provision for moderate heating of the bedroom and a warm dressing room may be necessary in cold weather.

5. "In addition to the ordinary hygiene of factories and workshops, such as proper space, air, ventilation, water supply, lighting, heating, drainage and plumbing, ordinary cleanliness and absence of dust care should be taken that women and children do not work too long at a time or at occupations involving the use of poisonous or deleterious materials; that there are ample toilet and lavatory accommodations, and that these are separate and away from those used by men; there should also be opportunity to sit, and women should not be expected to remain standing for long periods of time."—(Scott's *State Board of Physiology and Hygiene.*)

6. "*Nitrates* may be found in pure water from deep wells in the chalk, but as a rule are due to oxidation of organic matter of animal origin. Even if accompanied by only a small proportion of organic matter nitrates in water from a source open to suspicion must be regarded as oxidized filth, which may at any time be followed by unoxidized filth. A trace of nitrates not exceeding N = 0.35 per 100,000 would not suffice to condemn a water otherwise pure.

"*Nitrites* must be considered as pointing to sewage contamination, and their presence should condemn the water. They indicate more recent and therefore more dangerous contamination than nitrates."—(*Aids to Sanitary Science.*)

7. The chief *city nuisances* are: Noise, smoke, dust, waste matters, gases and fumes, odors and various offensive trades (such as the keeping of live animals, the killing of animals, the sale of animals, the manufacture of animal products, carpet beating, smelting and chemical manufactures). About *country homes* the nuisances which are the most in evidence are the improper disposal of waste or refuse material and the keeping of live animals.

8. To *prevent the spread of infectious diseases:* They should be reported to the health authorities; adequate isolation and quarantine (when necessary) should be enforced; proper prophylactic measures (as vaccination) should be ordered; children, from houses where there is such disease, should not be allowed to mingle with other children; proper disposal should be made of sputum and excreta; details bearing upon the prevention of each disease can be learned from special manuals on the subject.

9. (*a*) *Medicolegal complications which may arise from an erroneous diagnosis of pregnancy:* The character of the woman may be involved; the legal rights of the child may be involved; the paternity of the child and the mother's right to demand from the father support for the child are also involved; inheritance of titles and property are also to be considered.

(*b*) The practitioner should be very careful in making a diagnosis of pregnancy; he should remember that the *positive* signs of pregnancy are not present during the first few months; in doubtful cases he should maintain a strict silence, remembering that time will aid in making the diagnosis sure.

10. *Etiology of multiple neuritis:* The disease is said to be due to the action of poisons (in the blood) on the peripheral nerves. These poisons may be: Alcohol, lead, arsenic; diseased conditions as gout or syphilis; and bacterial toxins, such as are found in specific fevers, sepsis, etc.

OPHTHALMOLOGY, OTOLOGY, AND LARYNGOLOGY.

1. *Indications for iridectomy:* (1) Glaucoma; (2) some cases of chronic and recurrent iritis and iridocyclitis; (3) complete circular synechia; (4) partial corneal staphyloma; (5) tumors and foreign bodies in the iris; (6) recent prolapse of the iris. (From May's *Diseases of the Eye.*)

2. *Staphyloma* is a bulging of the cornea or sclera. It is due to inflammation.

3. *Chronic dacryocystitis* is *caused* by obstruction of the nasal duct. The *symptoms* are: Epiphora, fulness in the region of the lacrymal sac and the escape of a viscid fluid when pressure is made on the distended lacrymal sac.

4. "*Suppuration in the frontal sinus* is attended with frontal headache, vertigo, especially on stooping, and tenderness on pressure, particularly over the internal orbital angle, or on percussion over the frontal region. Pus escapes into the middle meatus of the nose, and if wiped away will reappear if the head is bent forward for a few minutes. After removal of the anterior end of the middle turbinated bone it may be possible to catheterize the sinus and wash out pus from its interior. The diseased sinus may present a darker shadow than the healthy one on transillumination or in an *x*-ray photograph. The *treatment* consists in exposing the anterior wall of the sinus by an incision in the line of the eyebrow, chiseling away sufficient bone to admit of free removal of all infected tissue and establishing efficient drainage through the infundibulum into the nose."—(Thomson and Miles' *Manual of Surgery.*)

5. *Aphonia* is loss of voice due to some interference with the vocal cords. *Causes:* Laryngitis, edema of the glottis, retropharyngeal abscess, excessive use of the voice, tumors of the larynx, foreign bodies in larynx, inflammation of the laryngeal nerves, paralysis of the laryngeal muscles, and hysteria.

6. "*Hyperemia of the labyrinth* may result from middle ear inflammation, exanthematous diseases, mumps, some intracranial disease, cessation of menstruation, disease of the heart, excessive use of alcoholic liquors, quinine, amyl nitrite, prolonged irritation from the use of the telephone receiver and vasomotor disturbances. *Symptoms:* There is present a sense of fullness in the ear, with ringing and roaring sensations and sometimes giddiness, nausea and vomiting. The symptoms are somewhat intensified by the horizontal position."—(Kyle's *Diseases of Ear, Nose and Throat.*)

7. *Rupture of the membrana tympani* may be caused by direct violence, such as blows or by instruments introduced into the meatus; or by indirect violence, such as the sudden condensation of air in the meatus, which may be produced by an explosion or the firing of a heavy gun in the immediate neighborhood; traction on the auricle, inflammation, irritating substances, and vegetable growths may also cause rupture of the membrane. *Symptoms:* Sudden and severe pain, impaired hearing, hearing subjective noises, vertigo, a watery discharge in the meatus, a whistling sound in the ear when the patient blows his nose.

8. *Acute circumscribed otitis.*—The symptoms are a feeling of fullness in the ear, a slight itching sensation, pain in the ear with tenderness on pressure, swelling in the auditory meatus which causes stenosis and slight deafness, tinnitus, pain on mastication, and increase of the pain and discomfort; the neighboring lymphatics may become involved, in which case there will be rise of temperature to about 100° to 101° F. There may be slight constitutional symptoms.

9. POSTNATAL ADENOIDS. *Symptoms:* Mouth breathing; snoring; open mouth; a vacant, dull expression of the face; modification of the voice (nasal twang), with inability to pronounce certain letters.

Treatment consists in early and complete removal by curette or forceps.

10. INTUBATION. *Indications.* Dyspnea from diphtheria or membranous laryngitis, stenosis, tumors, and some forms of paralysis of the larynx, and edema of the larynx.

Method: The child is wrapped in a blanket to control the arms and legs and is held upright by a nurse seated in a chair, while an assistant holds the head upon the nurse's left shoulder and prevents the mouth gag from slipping. A long piece of silk is passed through the small opening in the upper part of the tube, the tube fastened to the introducer, and the silk looped around the little finger. The left index finger is passed into the throat and lifts the epiglottis while the tube is passed along it into the glottis. The left index finger is then made to press upon the head of the tube, which is released by pulling the trigger on the introducer, which is then withdrawn. When one is assured that the tube is in the right place and that the symptoms are relieved, the silk loop may be cut and withdrawn while the finger is again made to press down on the tube.—(Stewart's *Surgery.*)

ACHYLIA GASTRICA;

A STUDY OF SIXTY-FIVE CASES

BY ALBERT F. R. ANDRESEN, M.D.,

BROOKLYN, N. Y.

IN medical literature of recent years there has been a decided scarcity of articles relating to achylia gastrica. This is unfortunate, because, while by no means an uncommon condition, it is probably less frequently correctly diagnosed by the average practitioner than any other stomach condition. In a critical study of between six and seven hundred cases of all kinds in the gastrointestinal clinic of the Brooklyn Hospital Dispensary, sixty-five, or about ten per cent., were found to be suffering from achylia. In private practice the percentage would undoubtedly be lower, because among the better classes we do not see the neglect and abuse of the body which play such an important role in the etiology of this condition. Nevertheless probably five per cent. of all patients with gastric disturbances would be found to have achylia gastrica if properly examined. The present paper is based upon a study of the sixty-five cases referred to above.

Strictly speaking, achylia gastrica is the name given to a condition characterized by an entire absence of gastric secretion, *i.e.* an absence of hydrochloric acid as well as of the enzymes, pepsin and rennin. By common consent, however, it is now understood that the term includes all cases in which there is an absence of free hydrochloric acid in the gastric contents, although enzymes and some combined acid may be present.

Concerning the *etiology* of achylia there has been considerable discussion and doubt. Some authors have attempted to show that a large proportion of cases is of functional origin, others, that it is always of organic origin. While it must be admitted that there may be a congenital weakness or anomaly of the gastric mucosa, accompanied by achylia, in adults it is always well to look for some organic cause for this condition, either within or without the stomach. To better understand the generally accepted theories concerning the etiology of achylia, it is well to consider briefly the three factors necessary to the production of normal gastric secretion, viz., (1) normal gastric glands, (2) the presence of HCl producers or enzyme activators in the blood, and (3) a normal central and peripheral nerve-supply to the gastric glands. Abnormal conditions affecting any of these three factors may produce achylia gastrica. Therefore, in considering the generally accepted theories regarding the etiology of achylia, we can take up abnormalities of each of these three groups separately.

I. *Abnormalities of the gastric glands,* producing achylia, may be of three kinds, viz.: (1) Functional, *i.e.* a condition in which normal glands do not produce normal secretion. I do not feel that this condition is often met with, except possibly as a developmental anomaly. (2) Inflammatory conditions of the gastric mucosa, either (*a*) catarrhal, as a result of chronic irritation from the ingestion of alcohol or nicotine to excess, or improper or insufficient masticated food, or (*b*) infective, as a result of primary foci of infection elsewhere causing a general inflammatory condition of the gastric mucosa (89 per cent. of my cases showed infections of the mouth, nose or throat). (3) Atrophy of the gastric mucosa, as a result of (*a*) chronic inflammation as above; (*b*) arteriosclerosis with attendant sclerosis of the mucosa; (*c*) new-growth pressing upon or destroying the secreting cells, such as carcinoma, sarcoma, fibroma, gumma, or extensive scar tissue from chronic ulcer; (*d*) distant wasting diseases, such as tuberculosis, intestinal parasites, chronic malaria, diabetes, plumbism, sprue, pellagra, etc.

II. *Diseases of the blood,* which might be a factor in causing achylia by impairing the bodily nutrition or by interfering with the carrying of HCl producers or enzyme activators, include: (1) Anemias and leucemias. Pernicious anemia, long recognized as an accompaniment of achylia, has been attributed by some to be the cause, by others the result, of achylia. Chronic gas poisoning may cause achylia by virtue of the destruction of blood which it causes, or by direct poisoning of the glands. (2) So-called gouty conditions and intestinal or other toxemias. (3) Syphilis, tuberculosis, or any form of septicemia. (4) Diseases of the glands of internal secretion, about the function of which, especially in regard to digestion, there is still considerable doubt, but which undoubtedly play an important part in producing or activating gastric secretion.

III. *Abnormalities of the nervous system,* which might interfere with the normal innervation of the gastric glands, producing achylia. These are exemplified in tabes, during the crises of which there is as a rule an achylia, and by the still largely theoretical states known as vagotonia and sympathetico-tonia. Under this heading might also be classed chronic infections or other abnormal conditions outside the stomach, such as pelvic disease, gallstones, appendicitis cases, especially postoperative, and extensive ptoses, which are supposed to act reflexly through the nervous system in producing achylia.

The contention that achylia gastrica is essentially a disease of those past middle life is borne out by our series, the average age of our patients being 43.9 years, and 23, or 35 per cent., being fifty years of age or older. Of 65 patients, 29, or 44.6 per cent., were males, 36, or 55.4 per cent., females, the apparent disagreement with the usual belief that

more males are affected being probably due to the fact that the total number of female patients in the clinic far exceeds that of the male. Bad teeth, that is, gross evidences of decay and infection, were found in 58, or 89 per cent., of our cases. Other conditions which might have played an important part in causing the achylia, arranged in the order of the frequency of their occurrence, are shown in Table A.

Table A.

Disease.	Number.	Per Cent.
Pelvic disease	11	17
Chronic alcoholism	10	15
Tuberculosis	10	15
Cardiovascular-renal disease	8	11
Gastric carcinoma	6	9
Gallstones	3	4.5
Appendectomy (postoperative)	3	4.5
Goitre	3	4.5
Diabetes	2	3
Chronic malaria	2	3
Chronic gas poisoning	2	3
Miscellaneous	6	9
Total	65	100

A *simple explanation* of the cause of achylia which has not before been suggested, and substantiation of which does not as yet exist, would be that, except possibly in congenital cases or in those due to tumor or disease of the glands of internal secretion, it is always due to a chronic generalized hematogenous infection of the gastric mucosa, probably by the *Streptococcus viridans*, as a result of a primary focus of infection elsewhere. The stomach would be made a locus minoris resistentiæ by abuses such as the excessive ingestion of alcohol, nicotine, insufficiently masticated food, or other irritants, or by sclerosis from arteriosclerosis. Neglect of the teeth is usually an accompaniment of chronic alcoholism, and is also common in older persons. In our series, the large percentage of infections of the mouth, nose, and throat (over 90 per cent.) would account for the primary focus of infection in these cases, as would pelvic infections, tuberculosis, syphilis, septicemia, etc. The explanation of the occurrence of achylia after operations for infections of the appendix, gall-bladder, and pelvis would be that the manipulations at operation threw into the circulation infective material which localized in the already reflexly irritated stomach wall. The finding of streptococci in the blood of the patients with achylia and pernicious anemia would also be explained. The anemia might even be explained by the presence of a coincident infection of the hematopoietic organs. This theory would also explain the periods of exacerbation and remission of symptoms in pernicious anemia, so much resembling those of chronic arthritis or appendicitis. In this connection, the frequent association of achylia with chronic joint troubles is suggestive. Even in carcinoma cases the achylia might be due to a complicating infection of the mucosa, it being usually true that carcinoma does not cause achylia until ulceration occurs, and this ulceration is probably an infective process. This infective theory is one which might well be investigated.

The *symptoms* of achylia gastrica may often be very indefinite, and there may even be no symptoms for a considerable length of time, as long as pancreatic and intestinal digestion remain normal. In our 65 cases the average duration of the symptoms before the patient applied to us for treatment was two and one-half years. Pain or distress at variable times after eating, often relieved by food or alkalies or by lying down, occurred in 57, or 87 per cent. of our cases. Sour regurgitation occurred in 29, or 44 per cent., vomiting in 23, or 35 per cent., of which two, or 3 per cent., had hematemesis. The bowels were regular in only nine, or 15 per cent., of the cases, constipation occurred in 36, or 55 per cent., and chronic diarrheas in 20, or 30 per cent. In the diarrheal cases the average duration of symptoms had been three and one-half years, as against two and one-half years for the whole series, suggesting the idea that the diarrhea is due to the long continuance of the achylia. Anorexia, muscular weakness, insomnia, and nervous irritability were usually complained of. Loss of weight usually occurred, but was not excessive.

The explanation of these symptoms lies in a study of the physiological effect of gastric juice containing the normal amount of hydrochloric acid. These effects are as follows:

1. Proteins are peptonized.
2. Connective tissue is changed so as to be digestible by the digestive ferments in the intestine.
3. The pylorus is closed through irritation.
4. The secretions of the pancreas and intestinal glands are stimulated.
5. The stomach and intestines are disinfected.

Insufficient disinfection allows free growth of bacteria, with acid fermentation, and the resultant organic fatty acids cause pain and distress, belching, and sour regurgitation. The fermenting, insufficiently prepared food is hastened into the duodenum through the relaxed pylorus, and the insufficiently stimulated pancreatic and intestinal secretions, sadly overtaxed, eventually fail properly to complete digestion. This results in irritation of the intestinal mucosa, causing a hurrying along of the intestinal contents, with resultant diarrhea, and, eventually, a catarrhal enterocolitis. The diarrheal movements, often enormous in size, usually occur after eating, the peristalsis and sphincteric relaxation excited in the stomach by the food extending rapidly along the entire intestinal tract.

The *diagnosis* of achylia gastrica depends upon gastric analysis. The only suggestive symptom is the diarrhea, although the history of chronic alcoholism, tuberculosis, and various other of the more common causes of achylia, associated with gastric symptoms, should make one suspicious of this condition.

The *gastric contents*, removed with the ordinary stomach tube one hour after an Ewald test meal, show an absence of chymification and an increased motility, the mass extracted being thick, moist, and sausage-like. There is also an absence of free hydrochloric acid, a total acidity usually under twenty, absence or great reduction in proteolytic and milk-curdling enzymes, and the presence of more or less mucus. Increased peristalsis is shown by the small amount of residue obtainable. In our forty-six cases examined in this manner, the total acidity averaged eleven. In the diarrheal cases, twenty in number, the total acidity averaged thirteen, so that the degree of acidity would not seem to be a determining factor in causing the diarrhea. The stools usually contain mucus and connective-tissue fibers, and, occasionally, occult blood.

For the past ten months we have been using the Rehfuss fractional method of test-meal examination in our clinic. By this method a fine tube with a fenestrated metal tip is left in the stomach throughout gastric digestion, and 6 or 8 c.c. of the contents after an Ewald test meal are removed at fifteen-

minute intervals until the stomach is empty. We have been able to confirm Rehfuss's contention that many cases called achylia because of the findings at the one-hour point after the ingestion of the test meal were really cases of delayed digestion, the acidity, as shown by the Rehfuss method, reaching normal, or even becoming higher than normal, after one and one-half or two hours. A true achylia must show absence of free hydrochloric acid in all specimens removed. Out of 190 cases of all kinds examined by the Rehfuss method, 19, or 10 per cent., showed a true achylia, the percentage agreeing, strange to say, almost exactly with the percentage of achylia cases previously found. In these cases the average highest total acidity was fourteen. Emptying of the stomach was very rapid in the simple cases, all residue being gone by the end of from one and one-quarter to two hours after the test meal was given. In pyloric carcinoma cases, and in a case of chronic ulcer at the pylorus, stasis was shown by a greatly delayed emptying and the presence of lactic acid and lactic acid bacilli. In the simple cases, bile regurgitated early, often by the end of one-half hour, due to the relaxed pylorus. Mucus was usually present to excess, and microscopically large numbers of bacteria, leucocytes, blood, and epithelial cells were found. An interesting finding was the invariable presence of blood in the contents. Visible blood was always found at some time during the procedure, but frequently occult blood would be found in the beginning and visible later. This finding is, of course, explained by the congested or atrophic and friable condition of the mucosa, and seems to obviate the necessity of describing as an entity an achlorhydria gastrica hemorrhagica, as has been suggested. In 16 of our 19 cases, or 84 per cent., occult blood was found in the stool after three days' meat-free diet. The finding of blood was not, however, constant, only occurring at irregular intervals.

Differential diagnosis, after an examination of the gastric contents has established the presence of an achylia, is practically confined to the determination whether or not carcinoma of the stomach is the cause of this achylia. The occasional occurrence of gumma, of other neoplasms than carcinoma, or of indurated gastric ulcer with achylia, should be borne in mind, although their differentiation from carcinoma, except possibly in the case of gumma, is not usually made before microscopical examination of sections of the tumor establishes the diagnosis. Aside from the finding of a gastric tumor, associated with symptoms of achylia, the following findings are suggestive of carcinoma as a cause of the achylia:

1. The constant finding of occult blood in the stools.

2. The presence of lactic acid, lactic acid bacilli, and infusoria in the gastric contents removed from a fasting stomach.

3. The finding of a considerable amount of albumin in the stomach washings—an index of 200 to 400 by the Wolff-Junghans method.

4. A Wolff-Junghans curve, in the fractional cases, rising rapidly and out of all proportion to the curve of acidity.

5. Excessive loss of weight and strength, even when the diet is sufficient, under normal circumstances, to cause a gain in weight.

The finding of fragments of carcinomatous tissue or of carcinoma cells in the gastric contents is, of course, diagnostic, but, like the finding of a palpable tumor, is too late to be of value to the patient. The most valuable aid in differentiating carcinoma in doubtful cases is undoubtedly the Roentgen ray. By means of serial Roentgenography, even the presence of early carcinoma of the body of the stomach, which it is practically impossible to recognize by any other means, can often be ascertained with a considerable degree of accuracy. The Abderhalden test for carcinoma, even if reliable as indicating the presence of a carcinoma, would not, in the absence of confirmatory evidence, be of any help in locating the carcinoma in the stomach, as simple achylia may occur as a result of carcinoma in a distant part of the body.

The *prognosis* in achylia gastrica depends upon its cause. In carcinoma the prognosis is bad, as carcinoma cases which are sufficiently advanced to show a total absence of free hydrochloric acid in the gastric contents are usually beyond hope of cure by operative procedures. In the presence of pernicious anemia, the outlook is decidedly unfavorable, although these cases will frequently have periods of entire absence of all symptoms, followed by acute exacerbations, as mentioned above. In other cases the prognosis as to life depends upon the prognosis of the coexistent disease. In the so-called cases of simple achylia, the prognosis as to life is good, the disease itself, under proper treatment, not being fatal, and not tending to the development of carcinoma or other serious complications. The chances of complete recovery of normal gastric function are not favorable, although we have seen many cases in which, after a course of treatment such as described in this article, the test meal showed normal findings in a few months.

Treatment.—The indications for treatment in achylia gastrica group themselves under the following general heads:

1. The removal of any infective foci, which, in addition to being a probable etiologic factor in the disease, tend to weaken the patient's reconstructive powers, so necessary to effect a cure. Operative treatment of such infective foci in the mouth, nose and throat and accessory sinuses, abdomen, pelvis or any other part of the body, should be preceded, if possible, by a course of dietetic and tonic treatment, and the use of autogenous vaccines of the streptococcus viridans, obtained from these foci of infection. This procedure would tend to prevent complications when operation would throw into the circulation large amounts of infective material. If the infective theory is correct, the use of the vaccines might also be of some theoretical value in hastening improvement in the condition of the gastric glands. In the few cases in which we have tried this method, improvement in the patient's condition seemed more rapid and more complete than in those where it was not used.

2. The treatment of any constiutional abnormality complicating or possibly acting as a causative factor in the achylia. This would include treatment of the anemias, leucemias, malaria, syphilis, tuberculosis, cardiovascular-renal diseases, rheumatic conditions, alcoholism, etc. In addition to treatment specific for any of these conditions, tonics would be indicated. I have been in the habit of combining ferric chloride and calcium chloride with the hydrochloric acid usually given in this disease. The use of the so-called bitter tonics before meals may in some people have some effect

in stimulating the appetite, but no effect on the gastric secretion may be expected, as shown by the recent researches of Carlson and others. The best tonic after all is a proper diet, and this will be discussed in detail later on. Exercise, especially in the fresh air, gymnastics, baths and change of scene are of value. Abdominal massage and electricity may be used.

3. The treatment of the diseased stomach must have as its keynote the conservation of its motor function. With the secretory function impaired, the motor function is of the utmost importance, and any measures such as over-feeding, or over-distention by careless lavage, should be avoided. Lavage was formerly a very popular procedure, but has more recently been practically abandoned. The amount of mucus removed by this method is probably more than compensated for by the subsequent increased secretion of mucus by the irritated stomach. A tumblerful of hot water given one-half hour before meals has a cleansing effect, besides being a valuable addition to the diet. Mineral waters are not necessary, but where given should be those which contain sodium chloride as a principal constituent. Mineral oil, given in tablespoonful doses, morning and evening, is soothing to the irritated gastrointestinal mucosa, and, besides being of value in relieving constipation, is not contraindicated in diarrhea.

4. Dietetic Treatment: The diet should be concentrated, and should consist of small amounts of food frequently repeated, preferably every two and one-half or three hours. The food should be in such form as to cause the least possible irritation to the diseased mucosa, and to require little or no alteration to make it digestible by the intestinal secretions. To prevent putrefaction it is best at first not to allow any kind of *meat*. For the same reason *eggs* should not be allowed unless soft-boiled, and then only in moderation, not more than one or two a day. It is better to derive the necessary protein of the diet from vegetables, or from nuts in moderation. *Gelatin* is also valuable as a protein sparer. *Milk* should be an important part of the diet, and it is well borne except in some diarrheal cases, where it seems to cause more irritation of the bowel. Frequently, however, this tendency to irritation can be overcome by having the milk peptonized, or acidulated with dilute hydrochloric acid, one dram to a glass of milk, added just before the milk is taken. It has been our experience that buttermilk and artificially soured milk are not well borne.

Carbohydrates form a valuable part of the diet in these cases. *Starches* are best given in such a form that the protein envelope, which requires digestion by the gastric juice, shall have been broken. For this reason strained vegetable soups, or purees, of potatoes, peas, beans, lentils, spinach, or carrots, are valuable. Thoroughly cooked cereals and puddings, served with cream or with stewed fruits or fruit juices, are tasty and easily digested. Flaked or shredded cereals are also good, as are bread, toast, and simple crackers. The so-called "vegetable meat" preparations, made of vegetables and nuts, provide an agreeable variation to the diet. *Sugars* are of value, but must be taken in moderation to avoid acid fermentation in the bowel, as evidenced by sour stools. The less fermentable sugars, such as lactose or maltose, may be added to the diet to increase its fuel value.

Fats and oils, in the form of butter, cream, olive oil or yolk of egg, are good to add to the caloric value of the diet, and also tend to soothe the irritated gastric mucosa. Taken to excess they are bad, especially in the presence of diarrhea.

Beverages, besides milk, which may be allowed, include cocoa, weak tea or coffee, or, better, cereal coffee substitutes, and fruit juices. The use of alcohol in any form should be interdicted, as should be the use of tobacco.

In a general way, the diet should consist of between two and three thousand calories, a little more than the amount required in the average normal person. The best index of a proper diet is the patient's weight. In a debilitated, undernourished patient, an increase in weight is necessary; in no patient is loss of weight during treatment admissible. A good sample diet for a single day, consisting of 2,515 calories, is shown in Table B. By varying the nature and quantity of the different constituents, such a diet can be made acceptable, or even agreeable, to the patient.

TABLE B.

Food.	Quantity.	Calories.	
BREAKFAST.			
Apple sauce	4 ounces	75	
Milk	6 ounces	125	
With cocoa or lactose	½ ounce	40+	
Cereal	4 ounces	75	
With sugar	1 dram	25	
With cream	1 ounce	50	
Egg, poached, on toast	1 egg, 1 slice	150	
Bread and butter	1 slice	65	605
10.30 A.M.			
Milk	6 ounces	125	
With lactose	½ ounce	40

5. The use of hydrochloric acid and enzymes is a subject about which there is still considerable controversy. Probably the most valuable aid in relieving the symptoms of achylia gastrica is the use of hydrochloric acid. While this acid cannot of necessity be given in such quantities as to insure a concentration in the gastric contents even approaching the normal, its effect, even in small doses, is remarkable. The distress and sour regurgitation after eating are quickly relieved. Vomiting usually ceases at once, and diarrhea, in my experience, has been always controlled within a few days, being often followed by obstinate constipation. The beneficial effects following the use of hydrochloric acid can be ascribed to the fact that its ingestion produces effects similar to those produced by the normal acid in the stomach, viz., a stimulation of gastric, intestinal, and pancreatic secretion, a

changing of pro-enzymes into active enzymes, an improvement of amylorrhexis by aiding in the digestion of the starch envelopes, and an antiseptic action. The dose of the acid should vary from fifteen drops to one teaspoonful or more of the dilute hydrochloric acid, preferably beginning with larger doses and reducing their size as symptoms are ameliorated. It should be given one-half hour after eating, well diluted with water, and swallowed through a tube to avoid burning the teeth. By dissolving one teaspoonful of cane sugar in the wineglassful of water, etching of the oral mucosa can be further avoided. A substitute for the acid, supposed to be less disagreeable to the patient, is acidol, a hydrochloride of betain, which is said to form nascent hydrochloric acid on reaching the stomach. The dose is from 10 to 30 gr., each grain representing one minim of hydrochloric acid. It is expensive, and not much better liked by patients than the very cheap acid, given as above described.

The use of enzymes and activators, at one time very fashionable, has now largely fallen into disuse. Pepsin is usually being excreted by the gastric mucosa long after the hydrochloric acid has disappeared, and needs only the acid to activate it. Another fact to be borne in mind is that enough dilute hydrochloric acid could not be given by mouth to produce the hydrochloric acid concentration necessary for pepsin action. The use of preparations of pancreatic glandular extracts, such as pancreon, pancreatin, and other similar preparations, is not of much value, especially where hydrochloric acid is given, as this destroys their activity. The use of secretins has not proved clinically to be of any value.

Conclusions 1. The usually indefinite symptoms of achylia gastrica warrant careful search for this condition in all cases of gastric disorder.

2. Its diagnosis depends upon gastric analysis, and the Rehfuss fractional method of test meal examination is the most satisfactory to use.

3. Knowledge of its etiology is still uncertain, but the infective theory should be investigated.

4. If an infection, the term gastritis, or better, endogastritis, would not be a misnomer for this disease.

5. Acceptance of the infective theory demands the removal of infective foci as a part of the treatment, and points the way to efficient prophylaxis.

6. Diet and the use of dilute hydrochloric acid are the other important items in the treatment.

Arthritism. — Bazin and Bouchard described under the names "arthritism" and "slackening of nutrition" a group of conditions, including gout, asthma, rheumatism, gravel, gall stones, obesity and diabetes, which are frequently met with in the same individual or the same family, and which are transmissible by heredity and are interchangeable: a gouty subject who has or has not diabetes may have a child who develops diabetes, asthma, or gravel, etc.—Cornwall in the *Medical Times*.

THE HORMONE EQUATION OF THE PSYCHOSES.

BY C. R. CARPENTER, M.D.,

EAST SAN DIEGO, CAL.

IN the recent work of Harrower, entitled "Practical Hormone Therapy," Bayle is quoted as saying, with reference to his extensive use of the spleen, that it is "perfectly innocuous." The writer has used the spleen therapeutically quite extensively in many conditions, notably in malarial infections; and while in the main, owing to the marvelous power of the endocrine organs to adapt themselves to circumstances, the observation of Bayle is correct, experience has shown that in a certain number of cases this power of adaption fails, and symptoms of a grave and alarming character supervene.

If this happens only once in a thousand times, and there is little doubt that it happens much oftener, its character of being "perfectly innocuous" is no longer sustained. Indeed, we are at once placed under the imperative obligation to study the conditions under which this happens, and if possible to find the remedy. For hormone remedies are being used more and more widely all the time, and are destined to take a commanding place in the field of medicine.

For this reason it is considered of the highest importance right at this point to make a somewhat sweeping statement, of far-reaching significance, which the present paper will endeavor to substantiate.

That statement is this: In the treatment of any disease by the administration of the spleen, it is not safe to give it alone; and it should never be done.

The mere fact that it has been given for long periods of time, in large numbers of cases, apparently without bad effects, simply renders those effects, when they do appear, more difficult to understand. It is more than probable that they have occurred frequently without a suspicion of the real cause. After many years of observation, the conviction has been formed in the mind of the writer, that the spleen is a remedy of remarkable power in the treatment of many diseases, especially those of an infectious character.

It is more than a remedy. The evidence is continually growing that it forms the center of a group of organs, which constitutes what is now known as the "defensive mechanism of the body." It is the functioning of this group of organs, modified by numerous accessory glands to meet the special requirements of different infections, that has been known in past years as the *vis medicatrix naturæ*, the healing power of nature, the natural resistance of the body, and by many other like terms.

It is upon this force that physicians in all ages have relied for their curative effects. No physician worthy of the name expects to accomplish anything for his patient without it. The most modern physicians with the most modern methods rely upon it the most. Whether they use antitoxins, bacterins or what not, nobody claims that they have any direct curative power. It is freely admitted that they depend for their action upon calling forth an expression from the defensive mechanism of the body.

But no force of great power can exist in nature without the possibility of doing harm. It must be controlled, and its power limited to doing good and not evil. So it is with the spleen. Nature does not contemplate its acting to the detriment of the in-

dividual. And so this strange and powerful organ is hedged about in its functions, and controlled in the exercise of its power by the other glands and organs with which it is associated, so that it may not become a Frankenstein in the physiological and pathological world of its operations.

But, as has been said, there are times when these endocrine restraints fail; and when they do, results follow that are sometimes of the direst character. It is earnestly hoped that the sidelight thrown by this little study upon a long darkened subject, may result in giving to the world an adequate knowledge of the true cause of mental alienation, and a rational treatment for the condition.

When the spleen was first used in the treatment of malarial infections, its effects were so marvelous that it was thought the fundamental basis of all natural immunity had been discovered. When an effort was made, however, to use the same remedy in other infections, no such brilliant effects were produced; and in most cases it failed utterly. Even in the treatment of malarial infections it was found that notwithstanding its brilliant effects in the large majority of cases, there were also cases in which it failed to a greater or lesser degree; and some in which it failed entirely. It was found that these patients were uniformly anemic, from blood lysis. Naturally, a hematinic was given; and when this was done the effect was quite as satisfactory as in other cases.

It just happened, however, that the hematinic used was one which contained a considerable content of pepsin; and it was found that when other preparations of iron or manganese were used, the effects were not so good. But still deeming the raising of the hemoglobin the necessary point, the red bone marrow was used, as being theoretically the ideal hematinic to use in this connection. This also failed completely, notwithstanding it had been used with great confidence. By the process of exclusion, then, the conclusion was inevitable that the pepsin content had more than the significance of a digestive substance. Its effect was too spectacular to be due merely to the improvement of digestion, which, in many cases, needed no special improvement.

Evidently the combination of the pepsin with the spleen supplied some need on the part of the spleen, which enabled its hormone to activate the exhausted phagocytes, and give them power to cope with the invading army of plasmodia.

With apologies to Sir Almroth Wright, if a phagocyte is quiescent in the presence of a disease germ, it is not wholly because it feels the lack of a condiment to tickle its appetite, but because it lacks the power of aggressive action. And it lacks the power because the spleen and its complementary organs have been so weakened by the infection that they fail to supply to the circulation the necessary hormones either in quantity or quality.

About ten or twelve years ago a colleague who had been interested in the use of the spleen by papers on the subject, presented by the writer in the local society, announced that he was "Done with using the spleen!" Upon being asked why he expressed himself in such an emphatic manner, he said, "Because it made by patient crazy!" The writer being at that time quite as certain as Dr. Bayle that the spleen was "perfectly innocuous," assured him that such a thing was quite impossible. And the intimation was dropped that his patient was probably crazy before he took the spleen.

"No, sir," said the doctor emphatically, "I knew my patient very well, and he was never crazy till he took that spleen. He is a raving maniac now."

The termination of this case is unknown, but, needless to say, it was at this time like an explosive bomb thrown into the camp. A great fear came into the writer's heart when he recalled the free and almost unlimited use that had been made of this remedy. Unlimited, that is, so far as was at that time known. But the overruling power which guides children and those who invade the dark secrets of nature without the lamp of knowledge, had guided better than he knew. Upon reflecting that the free use of the remedy had been uniformly without bad effects, however, the conclusion was reached that the case related had been a *post hoc* and not a *propter hoc;* and the work was continued.

Case I.—A year or so after this, however, a case of estivoautumnal fever came under treatment. This form of infection is much harder to control with spleen, as well as with quinine, than the tertian form. Indeed, the limitations of the spleen in the treatment of malarial infections, as has been remarked before,* parallel very closely the limitations of quinine. So much so that the question is very naturally suggested: Are not the effects of quinine in the treatment of malarial infections largely due to a stimulation of the spleen, causing it to throw off into the circulation the hormone, which undoubtedly produces the curative effect when it is given internally in those infections?

In the case cited, therefore, the remedy was being pushed; and as the patient did not show marked anemia the pepsin hematinic had not been given, when the patient began to show aberrations of the mind. Delirium, however, is not uncommon in such cases; and the family said of this patient that he always became delirious when he had fever, so nothing was thought of it. He did not improve, however, but grew steadily worse. Quinine was substituted for the spleen, but although the temperature came down the patient was no better. It was noticeable that when his temperature came down his mind did not clear. He grew steadily weaker, failing to respond to any means of stimulation, and died without recovering his mind at all.

Whether this patient would have died anyhow it is, of course, impossible to say, but in the light of subsequent studies, it is now believed that the mental symptoms were produced by the spleen. Whether it contributed to his death is to be doubted, but certainly it did nothing to prevent it.

One other case was necessary in order to educate the writer to the point where it was recognized that beyond a doubt the spleen under certain conditions was capable of producing grave mental symptoms, if not indeed contributing at least to a fatal issue. The effect of the spleen in the treatment of cancer had been under observation for some time. Several cases had been treated by local application with gratifying results, and it was thought that better results might be produced by using it subcutaneously.

Case II.—A case soon presented itself in a lady whose husband said she was dying of a cancer of the neck. He had heard of the experiments cited, and was willing to try anything that offered the slightest hope of benefit. The patient was about 40 years of age, fairly well nourished, and not especially cachectic in appearance. The growth was a lobulated carcinoma of the right side of the neck, fulminating in the rapidity of its growth. She was rapidly losing strength, and believed she was going to die. She was very calm and collected about the matter, however, even cheerful, and was much interested in the philosophy of the glandular treatment so far as it was explained to her. She was an unusually intelligent patient, and cooperated in carrying out the details of her treatment as far as possible.

After some days' treatment, ten minims of the solu-

*Medical Record, 1906, LXX, 165.

tion being injected subcutaneously every third day, the fulminating growth seemed to be somewhat checked, and there seemed to be room for encouragement. But just as it was beginning to appear that there might be some diminution in the size of the tumor, the husband telephoned one day that the treatment might as well be discontinued as his wife had lost her mind and was sinking rapidly. She died shortly afterwards without regaining her mind.

At first, grief and disappointment at the apparent failure of the treatment to give the relief it had seemed to promise, obscured a critical judgment of the circumstances of this case. But more and more as the facts were dwelt upon the question obtruded itself: did the administration of the spleen here produce the unbalancing of a mind that had seemed to be more than usually well balanced? The more they were dwelt upon, the more unavoidable seemed the conclusion that the breaking down of the mind had not been a merely natural step in the process of dissolution. And finally the conviction was reached that the spleen had been the direct cause of the mental alienation.

But if the spleen was capable of producing mental alienation in one case, why not in all cases? Evidently because the tendency to do so was held in check by some other organ or organs. What then were the conditions under which mental symptoms were possible? The memory of the other two cases recurred, and a careful scrutiny of the conditions was made. It was a long time before any comprehension of the circumstances came. But finally the fact was noticed that a least one condition was common to all three cases.

They all, for one reason or another, were deficient in sexual power. Not, of course, that they were sexually impotent; but the last case, for instance, was approaching the climacteric. The other two, though younger, presented conditions which suggested unmistakably a reduction in the power of hormone production by the sex glands.

What if the sexual hormone was deficient? What would it mean?

Clearly if a diminution of the sexual hormone caused the administration of the spleen to produce mental alienation, two very important deductions must be made. First, there is a possibility that all mental alienation, at least of a functional character, may be due to a coincident hypersecretion of the spleen and a hyposecretion of the sex glands. Second, if this deduction be correct, the administration of the sex glands in functional cases ought to restore the hormone balance, and hence restore normal mentality. Combined also with the spleen whenever it is administered, the sex gland should also prevent the production of mental symptoms in any case.

But what of the vast number of so-called cases of organic mental alienation? Would the administration of the sex glands alone correct them also? This seemed improbable. The intimate connection of diseased kidneys with many forms of insanity is well known, and it would seem that these organs must have an important influence on the spleen also.

Again, long previous experience with the administration of the spleen combined with digestive substances suggested that many more cases of mental symptoms might have been seen had not this precaution been taken, and that the digestive hormones must have also some restraining power over the spleen. This indeed was found to be the case, not only with the peptic hormone, but the pancreas and parotid.

The mammary glands also, except during pregnancy and lactation, stimulate the production of the sexual hormone, and hence assist in the restraining influence on the spleen.

Gradually by some such course of reasoning the elements of the following equation were brought together, with the determination that whenever an opportunity presented it would be tried out:

$2G + P + Pr + R + M = HB.$

Where G is the sex gland, P the pancreas, Pr the parotid, R the renal gland, M the mammary gland, and HB the hormone balance.

This presupposes that careful distinction is made between the sexes, which requires two different equations, one male and the other female. It is not best to combine the testes and ovary in one equation, as experiment has shown that the administration of such a combination may produce intense eye strain with painful ocular symptoms. This, by the way, is an important lead for further investigation.

A long time elapsed before an opportunity finally presented to make use of this theory. The case which first called for the administration of hormone equation No. 45, as it has been called, occurred at a time when the full hormone equation was not available. But as it was a purely functional case of puerperal mania, it was just as well, as it enabled the working out of the main point of the theory.

Case III.—The patient was a young woman 22 years of age, primipara. Labor was normal in every way except that as soon as chloroform was given she began to show aberrations of the mind whenever the anesthetic wore off. The aberrations took the form of violent abuse of the attending physician. The family was assured that she would be all right in the morning when the anesthetic had worn off completely. But the next morning she was as bad as ever, and it was quite evident that a genuine case of puerperal mania was in hand. Instantly the determination was reached to put to the test the theory that had so long been in mind. Some small powders of ovary were prescribed containing about two grains each, with instructions to give one every two hours. Before the second powder was given the mind cleared perfectly. The rest of the powders were given but *only* to make assurance doubly sure. There has been no recurrence of the symptoms since.

Case IV.—The next case was that of a woman about 46 years of age, who had a cancer of the thyroid which was pressing on the laryngeal nerves so that it had threatened asphyxia from spasm of the glottis and tracheotomy had been performed. She had been under treatment for some time with the subcutaneous use of spleen and lymph glands. The ovarian solution had been combined with them with the idea of preventing any mental symptoms, and although considerable doses had been given no trouble had been experienced. As the tumor reduced rather slowly, however, it was thought to hasten matters by increasing the dose. Having, however, by this time a somewhat unwarranted confidence in the controlling power of the sex gland the dose of ovary was not increased. Not long afterwards the nurse rushed into the office with the information that the patient was out of her mind. That she would not speak, but just stared straight before her without giving any sign.

On going to the patient she was found in a state of profound typical dementia. The jaw dropped, the mouth open, the eyes leaden and staring, the face ashen and expressionless. A more perfect picture of complete dementia could not be imagined. Although a totally uneducated woman she had an unusually quick and keen mentality; so that the change in her appearance and manner was the more extreme, not to say appalling. But even in the excitement of the moment it was impossible not to note the radical difference between this type of psychosis and that of the former case, and to note also the probable cause of that difference. Instantly the ovarian solution was produced, but with fear and trembling; for who could tell

whether it would have the same happy effect in this new type of psychosis. A full dose was given subcutaneously, however, and the result awaited in painful suspense. In a few moments expression began to come back into the blank face. The still eyes began to move about from face to face, and in not more than thirty minutes the mind was entirely restored.

This patient finally died from a spasm of the glottis, before the tracheotomy tube could be reintroduced; but the importance of the lesson it teaches in the study of the influence of hormone secretions in the production of the two great types of mental disease, can hardly be overestimated.

It has been found in a study of the previous cases that a hypersecretion, or experimentally, an overdoes of the spleen alone, with a coincident hyposecretion or diminution of the sexual hormone, precipitates mental symptoms of a maniacal type.

In this case, however, we had mental symptoms of the second great type of psychoses, dementia, produced by an overdose of the spleen plus an overdose of the lymph glands, with also a coincident diminution of the sexual hormone. The woman was 46 years old.

So far as known, the lymph glands alone have never produced mental symptoms of any character; but, as will be shown by the next case, when combined with spleen they readily produce mental symptoms of a demential type, provided the sexual hormone is diminished.

Case V was that of an old gentleman 78 years old, with pyelitis and cystitis, in which there was profound constitutional sepsis. Wishing to diminish constitutional sepsis, the lymph glands and the spleen were used. Hexamethylenamin and other measures were used, of course, but they are of no importance in this connection, while surgical interference was positively refused. As long as the lymph glands alone were used no trouble was experienced, but wishing to intensify the effect, the spleen also was added to the treatment, guarding it with a small amount of testicle and the other elements of equation 45.

But evidently this patient, probably on account of his advanced age and his depressed condition, was particularly sensitive to the effects of the spleen and lymph glands, and the preventive measures proved to be insufficient. The next morning, on entering the sick room, the same picture described in the last case was presented. The dropped jaw, the open mouth, the ashen face and dead staring eyes of complete dementia. This patient was a man of unusual character, and a mentality above the average. As in the last case, the change was little short of appalling. But fortunately having the benefit of previous experience the emergency was met with greater confidence. The proportion of the sex gland was adequately increased, and before the writer left the house the symptoms had disappeared.

At least twice before the close of this case by his demise—his case had been hopeless from the start in the absence of surgical measures—he again exhibited these mental symptoms, when the preventive measures were inadvertently relaxed. Each time the symptoms were promptly removed by increasing to the proper point the proportion of preventive hormones.

This case, therefore, shows beyond a doubt that it is perfectly possible in susceptible individuals to produce the symptoms of dementia at will, and remove them with the same facility.

Case VI was different from the three preceding cases in that it was precipitated by what might be called natural causes. Mrs. McC. was a lady about 48 years of age, mother of a large family, several sons and daughters being grown. The family had suffered many reverses of such a severe nature that it was the subject of remark by all who knew them. Mrs. McC.'s general health, however, was good, and she was physically strong. She bore up admirably through all these trials until her eldest son, perhaps 25 years old, died suddenly one night in a terrific hemorrhage, under most distressing circumstances, after being bedridden for a year or more with tuberculosis.

The day after the funeral Mrs. McC. lost her mind, and was found wandering in a vacant lot, muttering incoherently, and aimlessly picking wild flowers and weeds. When she was found by friends, and they tried to take her home, she suddenly collapsed, and they had to carry her in.

When the writer reached her she was still in bed, muttering and talking incoherently. She was in just the state mentally that one would expect to lead to an ordinary case of melancholia. Indeed, if her condition were to be characterized by a name it would be most correctly described as melancholia, which is classified by some alienists as demential in type.

Is it not perfectly logical then to believe that in this case we had a hypersecretion of the spleen caused by grief and the accompanying powerful emotions plus a hypersecretion of the lymph glands, with a coincident hyposecretion of the sex glands?

And is it not logical to suppose that the difference between the symptoms of this case and those of the other two cases of typical complete dementia was caused by some difference in the relative secretions of the other glands which are known to exercise a restraining influence over the spleen?

Just what these differences are will have to remain for future investigation. But the significant thing about the case was that the hormone equation No. 45-F restored the mind quickly and perfectly. The next day the lady got up and went about her usual duties. A few days later she transacted most of the business necessary to collect the life insurance on her son, and has had not a sign of aberration since.

It is not too much to say that if this patient had been treated by the usual methods she would have found a place in the state insane asylum; and probably would have died miserably, or lived a living death.

This is a short case record, as the writer not being an alienist has taken the cases just as they have come to him in a general practice. But so illuminating is their character that it seems difficult to escape from the following conclusions:

1. The administration of the spleen is capable of producing insanity of either an active or a maniacal type.

2. Hence, insanity of this character is probably caused by a hypersecretion of the splenic hormone, either actual or relative.

3. In functional cases the hormone of the sex glands absolutely controls this condition, and prevents or removes mental symptoms.

4. The administration of the spleen and lymph glands may produce insanity of a demential type, and hence insanity of that type probably is produced by a hypersecretion of both the spleen and lymph glands, actual or relative.

5. The essential condition for the production of any of these effects is a diminution below the normal of the sexual hormone in the circulation.

6. The male hormone will not protect the female, nor will the female hormone protect the male, from mental symptoms.

7. The hormones of the kidneys, the digestive organs, and the mammary glands are important in their restraining effects upon the spleen and lymph glands, so far as their influence upon mental functions is concerned.

8. It is possible by combining these restraining hormones to develop a practical specific therapy for mental alienation.

9. By applying such a treatment early in the disease the old chronic incurable cases of organic insanity would be prevented, as the longer the condition exists the more extensive become the structural changes in the brain.

10. The division of psychoses into at least two main types, mania and dementia, is based upon etiology and is therefore scientific.

INFANT MALNUTRITION.

By WILLIAM HENRY PORTER, M.D.,

NEW YORK.

PROFESSOR EMERITUS IN PATHOLOGY AND GENERAL MEDICINE IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL, ETC.

THE study of metabolism and its disturbances is the one great and unsolved problem in medicine. It begins with conception, so far as the individual is concerned, and ends only in death. In so far as the coming generations are concerned, it should begin in a careful selection of life partners and be continued throughout life. For unless the fathers and mothers are anatomically and physiologically at their best during the child-bearing period, they cannot acquire the best possible progeny, and without the best, succeeding generations must retrograde. The nearer these ideals are approached, the more nearly will we come to practical eugenics. The following interesting case illustrates some of these points:

A healthy young woman was married at twenty to a healthy, robust man a few years her senior, Owing to the fact that her mother's kidneys were seriously involved during pregnancy, and she died of nephritis shortly after the young lady was born, it naturally made her somewhat fearful as to the outcome in her own case. She placed herself under my care shortly after she became pregnant. The diet and hygienic conditions were carefully and scientifically regulated, and the bowels were kept moving freely during the whole course of the pregnancy. The result was that the kidneys performed their function perfectly both during and following the pregnant state. The patient had a perfectly normal confinement and a strong and vigorous baby, one that has continued to grow strong and healthy in every respect, even though it was bottle fed. Some two or more years later she again became pregnant. In the meantime, however, she moved to another city and passed from under my direct care. For some reason or other during the second pregnancy, the diet and hygienic conditions were not as carefully regulated as in the former pregnancy. While the second confinement was perfectly normal and without any kidney complications, the baby was not nearly so strong and robust as the preceding one. The second baby had icterus neonatorum quite badly and it was with considerable difficulty that it was made to thrive at all. It also was a bottle fed baby. After several months, however, the baby apparently was doing pretty well, but never advanced in the regular and vigorous manner that a baby should. At about the end of six months, while the child looked fairly well, it was not gaining. It seemed to have little strength for its age, was but little inclined to do the things common to its age, and would lie upon its back by the hour, making no effort to roll over or sit up in a changed position. The baby was hardly able to sit up in the mother's lap unless the back was well supported. Doubt was expressed by some as to the power of vision, and to some it seemed mentally defective. There was no sign of any teeth. In the next four months the baby made no progress in weight or any other respect. Toward the end of this period the baby began to show signs of absolute retrogression, but without any positive signs of disease. There appeared to be nothing wrong other than faulty assimilation, and an arrest of nutritive activity. At the end of ten months there was no sign of any teeth, the baby could hardly sit up, and made no effort to creep or get upon its feet. There was no evidence, apparently, of any suffering of any kind on the part of the baby. Several experiments were made in the changing of food, but all to no avail. At this point the case was referred back to me for an opinion and advice as to what might be done for the child.

Just about this time a carbonated aqueous solution attracted my attention, one of high alkaline bases, and in which there was a high percentage of calcium carbonate with the CO_2. It was claimed that in consequence of these facts its use would speedily overcome the so-called "superacid conditions" of the animal economy. As a matter of fact these so-called "superacid" conditions are only diminished alkaline ones, for nature never allows the system as a whole to become acid. Some of the secretions may be rendered unduly acid, but nature always prevents absolute acidity, a state which is incompatible with the maintenance of animal life, and which is overcome by the withdrawal of the more fixed alkaline bases from the various structures of the body. This withdrawal naturally disturbs the alkaline balance of the animal economy which is absolutely essential for perfect metabolism, and various grades of disturbed metabolism ensue. Therefore, from a practical standpoint it becomes just as essential to overcome lowered alkalinity as it would be were it within the range of possibility to have an absolutely acid state of the system. On the other hand great care must be exercised not to overalkalinize the animal economy, for both extremes tend to disturb metabolism, the former, however, more than the latter. This solution has the following composition per hundred parts of water: Sodium carbonate (Na_2CO_3), 00.404; sodium phosphate (Na_2HPO_4), 00.023; sodium chloride (NaCl), 00.080; calcium carbonate ($CaCO_3$), 00.057; magnesium carbonate ($MgCO_3$), 00.004; potassium chloride (KCl), 00.004.

The one ingredient in this solution which appealed most of all to me was the sodium phosphate (Na_2HPO_4) a salt which is usually formed from the trisodic phosphate (Na_3PO_4) in the process of digestion when the hydrochloric acid is formed into sodium chloride ($Na_3PO_4 + HCl = NaCl + Na_2HPO_4$). This latter salt, the disodic phosphate, is quite abundant, relatively speaking, in the blood. It is also very essential for perfect metabolism, the maintenance of the normal acidity of the urine, and for the transformation of uric acid into sodium urate. In view of the above it occurred to me that this was a case in which to try the use of these alkaline salts. Hence, my suggestion to the mother was to make no change in the composition of the baby's food, but in its preparation I recommended the substitution of water containing the salts in the above proportions, for the water she had been using in preparing the milk, allowing time for most of the carbonic acid gas to escape before preparing the milk. Also to give a little of this water, decarbonated, between feedings. Very shortly after this change was made (about two weeks) there was marked evidence of improvement in the child's condition. At the end of four months the baby had regained all of the natural activities of a child of its age. During these four months the baby gained nearly four pounds, cut six teeth, and was able to stand on its own feet unassisted. A month later it gained more in weight, cut more teeth, and became very bright and lively in all respects.

While fully realizing that this is but one case, and covers only a short period of time, it seems worthy of reporting, especially in view of the fact that no further change was made in the diet and no medicine was given. Also, because the case appeared to be one of true and simple malassimilation, due to the lack of some essential element to maintain perfect metabolism. The results certainly point very strongly toward the elements given as the factors necessary for the reëstablishment of normal metabolism within the system of this unfortunate child, though one would, of course, have to see a large number of cases before it would be possible to affirm with absolute certainty that the good results obtained were directly due to the action of the salts.

One of the chief purposes of this paper is to bring to light another etiological factor in disturbed metabolism, to wit: the lack of alkaline balance, a very common cause and one not often recognized, and one which if neglected in the management of these cases prevents recovery in many instances. It has long been known that in many forms of malnutritive diseases of infants and young children, it often is not so much a lack of the mineral salts as it is a failure properly to utilize and assimilate them. On the other hand, if the proper physiological balance can be established in relation to these saline bases, they will normally stimulate sluggish and inactive protoplasm into more normal activity and finally bring about normal metabolism. It is a known fact that most of our modern methods of cooking usually deprive our vegetable food products of their natural salts so essential to perfect metabolism. Hence the brilliant results obtained by some physicians who prescribe for their patients the eating of uncooked or raw vegetables. Attention is again drawn to the fact that most of our disturbances of metabolism are due in part to a loss of this alkaline balance, which in its most pronounced form is at the present moment attracting much attention under the name of "acidosis," a condition in which there is a lack of these salts, or an inability to utilize them perfectly, with a vain effort on the part of the animal economy to draw these fixed alkalies from the structures of the body, with consequent increased acidity of many of the secretions, until we pass from a simple disturbed chemical function to one that brings about true pathological changes.

46 West Eighty-third Street.

A CASE OF AURICULAR FIBRILLATION.

By J. WHEELER SMITH, JR., M.D.,

BROOKLYN, NEW YORK.

W. W. came to me on February 16. He is a native of Ireland, is forty-seven years old and is unmarried. His occupation is that of grocery clerk. He complained of "a heavy cold" and presented cough, fever, and dyspnea. He stated that he awoke early on the morning of the ninth with a chill. He took quinine during the day. That evening he began to cough. He appreciated at this time that he was feverish. He continued to be up and about for an entire week, treating himself with drug-store "cough mixtures" and being attended by a "doctor" who worked in the drug store. Finally he was told that he should see a physician. He came to me on the eighth day of his illness. A relevant point in his previous personal history is that the patient had pneumonia seven years ago.

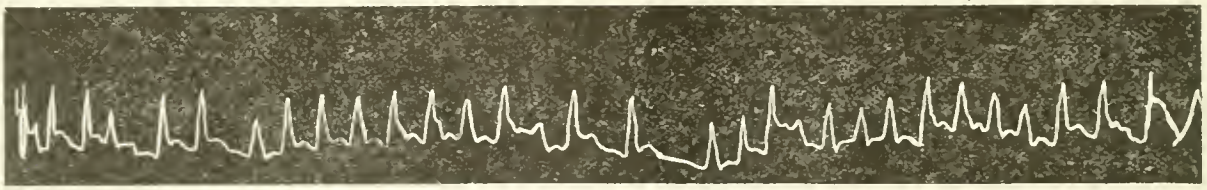

FIG. 1.—Sphygmogram made with Dudgeon's sphygmograph, Feb. 20, 1914, at 1.30 p. m. Right radial artery.

His temperature was 103°. I instructed him to go to his bed at once. At 8 P.M. of the same day I made the following observations of his physical condition: Patient in the dorsal recumbent position, apparently comfortable; quite lucid and cheerful. His skin was white, dry and hot. The conjunctivæ were congested; the scleræ injected. The pupils were of moderate size, equal and regular, and reacted well to light and accommodation. There was marked movement of the alæ nasi in inspiration and the lips were thin, pale and slightly cyanotic. No herpes labialis was seen. The tongue was soft, pale, indented by the teeth, and coated all over with a light white fur. The throat was uniformly reddened. The neck was symmetrical. There were marked arterial and slight venous pulsations. The thorax was of moderate size, fairly well nourished and symmetrical. The respiratory movements of the thorax were distinctly diminished all over the left side, over which side, also, tactile fremitus was increased. Both apices were dull. The right front, however, was resonant; but the left front was dull, merging below into a flatness which extended over the left axilla and base. Auscultation elicited harsh bronchial breathing over the entire left side, with many small moist râles and a few large ones. The cardiac apex was felt faintly and irregularly in the fifth space in the midclavicular line. The area of cardiac dullness was somewhat increased both to the right and to the left. The heart sounds were very weak and muffled and were markedly irregular both as to time and intensity. The rate was very rapid. Some of the sounds heard at the apex apparently represented contractions on insufficient blood to send a wave to the radial, hence the radial rate was considerably slower than the apex rate. The abdomen was slightly tympanitic. The extremities presented nothing worthy of note. I made a diagnosis of lobar pneumonia, involving both lobes of the left lung and of cardiac irregularity.

On the following day, the ninth day of his illness, dating from his chill, the patient was markedly cyanotic but quiet. The apex rate was 172 and the rhythm was still very irregular. The type of the irregularity was not yet determined, but it was quite definitely not a respiratory irregularity. Physical signs showed the entire left lung to be consolidated; there were numerous large moist râles over the upper lobe anteriorly. The back was not examined. Great difficulty attended the determination of the blood pressure because of the

marked irregularity of that factor. At times no pulse wave came through to the radial under pressure of 70 mm. Hg.; at times a pressure of 110 mm. Hg. was necessary to keep all back; sometimes even more. At 6.45 P.M. on the seventeenth the apex rate was 176. At 7 P.M. phlebotomy was done and sixteen ounces of blood drawn off. At 7.15 P.M. 1-200th grain of strophanthin was given intravenously in 10 c.c. of physiological salt solution. The apex rate was not appreciably affected, but the patient felt very much more comfortable. Leucocyte count at this time showed 30,000 white blood cells per cu. mm.

At 11.45 A.M. of the next day, the eighteenth, the patient was comfortable. The entire left side showed small and medium-sized crackling râles on inspiration, and harsh tubular breathing in front. The cardiac rate was 142 and the rhythm was still very irregular. The irregularity was certainly not a respiratory irregularity and did not sound like extra systole. There was no evidence of pericardial involvement. At 4 P.M. the apex rate was 156, the radial rate 98. The patient was breathing quietly and sweating profusely. At 8.30 P.M. the patient was still very comfortable. The apex rate was 160; the radial, 135. The breath sounds low in the axilla were more quiet, and were accompanied by large numbers of moist râles, both inspiratory and expiratory. Over the upper part of the left

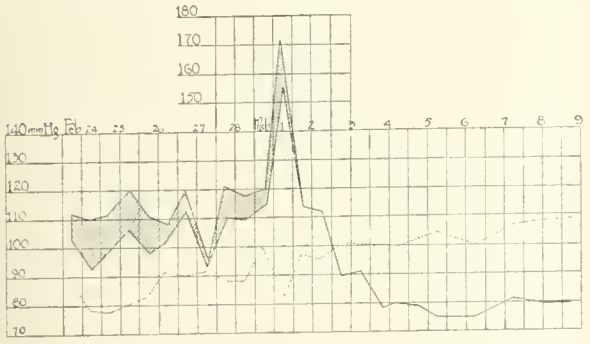

FIG. 2.—Tracing showing improvement under treatment.

front the sounds were very rasping and there were large numbers of inspiratory râles. There was no involvement of the right side.

On February 19, the eleventh day of the illness, the patient's temperature dropped rapidly from 103° to 98.4°. Resolution took place very slowly. Marked impairment of resonance, increased tactile fremitus and voice sounds and roughened breath sounds, with râles, persisted for ten days after the crisis.

Fig. 1 is a pulse tracing made on the twentieth, the day after the crisis. On the twenty-third the cardiac condition was diagnosed auricular fibrillation, the diagnosis resting upon the very marked irregular irregularity in the ventricular contractions, as appreciated both by auscultation at the apex and by palpable demonstration of irregularity in rhythm, force and volume of the pulse at the wrist. A second diagnostic point was the marked and constant pulse deficit. It was determined to put the patient upon digitalis. Digipuratum was employed in tablet form. Fig. 2 is a graphic record of the patient's improvement. It is drawn according to the plan of James and Hart (*Amer. Jour. Med. Sci.*, CLXVII, 1, Jan. 1914.) The cardiac rate, as auscultated at the apex, is represented by the upper line; the radial rate, as palpated, is represented by the lower line; the pulse deficit is represented by the shaded area between the two lines; the average systolic blood pressure is represented by the dotted line. Determinations were made daily at 9.30 A.M. and at 7 P.M. Observations were begun on February 24 at 4 P.M. No medication was given on the twenty-fourth, twenty-fifth and twenty-sixth, but was begun on the twenty-seventh; on that day and thereafter one tablet of digipuratum was given at 9 A.M. and another at 4 P.M. Each tablet is equivalent to 1½ grains of the leaves of digitalis. It will be seen that on March 1 the cardiac rate rose to 172 and the radial rate to 156. This rise in rate was concomitant with an elevation of temperature to 103.3°. At the same time the patient complained of great soreness in his right arm. Examination revealed large, inflamed, indurated areas in the subcutaneous tissue, which were acutely tender. It developed that the nurse, being unfamiliar with the method of administration of the tablets, had dissolved the tablet each time and injected the solution hypodermatically. In consequence, great irritation of the tissues was induced and a general response effected. Thereafter the tablets were given as intended, by mouth, and great improvement was had almost instantly.

Observations were discontinued on March 9. The medication, however, was continued. The patient was out of bed on the twelfth and paid me his last visit on the sixteenth, feeling, at that time, so he said, better than he had felt for a great many years.

1249 ST JOHN'S PLACE.

PERSONAL EXPERIENCES IN CONTRACT PRACTICE.

BY LUCIUS F. HERZ, PH.B., M.D.,
NEW YORK.
ASSISTANT SURGEON NEW YORK POST-GRADUATE HOSPITAL DISPENSARY.

TOWARD the end of my House-Surgeonship at the Post-Graduate, I was shown an advertisement in one of the prominent medical journals, which called for a surgeon for a large corporation in a town of 65,000. I wrote to the number given in lieu of definite address, and inquired for full particulars in regard to the position offered, and received the following letter in reply. For obvious reasons, names have been suppressed or changed.

BLANKVILLE, March 15, 1916.

Lucius Herz, M.D., New York City.

DEAR DOCTOR:—I am in receipt of your letter of date March 12, concerning position at the plant of the Blankville Steel Company.

The Blankville Steel Company is a subsidiary of the United States Steel Corporation and have just established a plant in this city that has cost $20,000,000. The future of the steel business is very bright in this locality and I have no doubt that this plant eventually will be among the largest in this country, and for the right man there will be a chance to grow with the industry. We now are just finishing a new surgical hospital at the plant, which will be modern in every way. We have a hospital right at the works where all minor work is done, also first aid.

I now have two men at this place, but have one who is unsatisfactory and will discharge him soon. The salary of $100 per month does not include board, but it does include room at the hospital. There is a good opportunity to build up a private practice that will eventually amount to many times this salary.

I am also looking for an assistant at my office, as my laboratory man and pathologist is going to leave me next month. There may be a chance for you to take his place, if you should prove the right man. I may give you a chance in my office and hospital work.

I demand the best credentials as to your moral character as well as your professional character.

This place is not filled yet as I am considering several applications, being anxious to get the very best man possible and one who is willing to work and grow up with the business.

Let me hear from you soon, as I am anxious to fill this place as soon as possible.

Very truly yours,

As I cared more for clinical than for laboratory work, I made a formal application for the position at the steel plant, and after some more correspondence, and investigating the references that I gave, I was accepted. Judging from the small salary named, and the statement regarding outside practice, I assumed that the position was a half-time position, similar to the New York City positions, requiring routine work for a few hours per day, and then being on call for serious emergencies only. The reader will shortly see, that in contract work, it is unwise to assume anything, and the only proper way to engage in it, if there is any proper way, is to have a signed statement specifying what one's exact duties consist of.

After a journey of 1,600 miles, I found myself in Blankville, and proceeded at once to the office of the writer of the letter. There I met Dr. ———, a shrewd and prosperous looking man of about sixty. After exchanging a few commonplaces, we "got down to business," and then, and not until then, I was given a true inkling as to what my duties would consist of. He broached the matter delicately by inquiring whether I had much night work at the Post-Graduate, to which I replied that I did early in my service, but toward the end, most of the night work was done by my juniors. He then announced that my work would consist chiefly of night work. I was, of course disappointed, but decided to face the proposition bravely, and if the chances for outside work were so wonderfully good, would gladly sacrifice an occasional hour's sleep. I did not even then surmise what my duties would be, as I assumed that only serious night cases would require my attention. Dr. ——— then took me out to the plant, introduced me to the superintendent, and showed me the new hospital, and then we returned to town. The plant was twelve miles from the center, and was reached by trains which were few and far between, but this additional disappointment did not fease me either. Then, Dr. ——— did the one act in all our dealings that I can feel grateful for; namely, he took me to the best hotel in town, registered me as his guest, engaged a parlor and bedroom for me, and told me to stay there over night, take my meals there, and charge it to him, remaining until the following morning. I thus had a refreshing night's sleep, the last for some time to come.

Dr. ——— informed me that I was to treat the employees for actual injuries under the Workingmen's Compensation Act, and that medical and other cases not resulting from injuries ranked as private practice, and that I would be permitted to charge for them. My hours were to be arranged by the senior surgeon at the plant, Dr. X.

The next morning, bright and early, I arrived at the plant, and met Dr. X, a man of about thirty-five, of the classical stage doctor type, goatee, very professional manner, etc. He informed me that I was to assist on the day dressings, from 9 to 12 A. M., could have the afternoons off, then come back at 7 P. M., do the routine night dressings until 9 P. M., and then sleep at the infirmary, and remain on call all night. The laborers were to knock at my door to arouse me. I was soon to learn that they were not at all reticent about disturbing my sleep.

My first night, I was aroused by feeling somebody rudely pulling at my foot. I awoke with a start, and found an ignorant, grimy, laborer at the foot of my bed. I thought an unusually serious accident made him dispense with formality, and asked what the trouble was, and was told "head cut." I made him wait outside, donned my bathrobe, and stitched up a slight scalp wound. Thus it went, several times each night, sometimes eight to ten times. Some few had courtesy enough to knock at my door, but the majority walked in and sat down, but were promptly informed that this was my bedroom, and that they were not permitted in there except at my invitation. I soon found out how people abused the privilege of free medical attention. Infinitesimally small scratches, tiny abrasions, "barked knuckles," slight bruises, cinders in the eye, slivers under the nail, etc. A long array of tedious, uninteresting cases, not nearly so interesting as the average dispensary clinic, because the motto of "Safety First" adopted by the Steel Trust, made the foreman send the laborers to me for ridiculous trifles. I soon realized that I had been tricked. I first vented my indignation upon X, and told him that if I had to work so hard nights, it was unreasonable to make me work days, and I refused to work longer at that schedule even for twice my salary. (Inquiry had revealed to me the fact that my predecessors worked nights only, and that X. was imposing upon me so that he could attend to his private practice.) X. agreed that it was pretty strenuous but thought that I should stand it. I was firm in my resolve, however, so he gave in, and said that I should work nights only. I found also that I was expected to work seven nights per week, and that it was utterly impossible to obtain a night off, as X. would not take my place evenings. I surely expected one night per week off, but was merely told, "You can't have everything you want." On the other hand, he never hesitated to ask me to take his place mornings or afternoons, when he was busy with a private case, and I was foolish enough invariably to consent.

Finally, loss of sleep began to tell upon me. The cases were rarely of any interest, and half the time could have been handled by a nurse or orderly. I became more and more tired. Five hours sleep out of the twenty-four was doing exceedingly well for me. I could fall asleep the first time I retired readily enough; the second time, perhaps after an hour's wait, and the third time not at all. Toward the last of my work there, however, I could not sleep at all, as I was completely worn out, and finally obtained forced sleep by taking trional. All this for what? For nothing! For a concern that worked constantly, day and night, day after day, an iron monster without heart or soul. My strenuous and conscientious work was paid for at the rate of $10 per month more than the lowest paid common labor! A fine recompense for seven years in college and two and a half in hospitals. The strenuousness of the work was unbelievable. Sometimes for two successive night I was aroused eight times. On every case, no matter how absurdly simple, in addition to treatment, I had to make out a detailed report in triplicate, giving the man's name, age, department, number, address nationality, cause of accident, party blamed, probable length of disability, description of injury,

treatment given, etc., etc. This generally required more work than the treatment of the case, and was absolutely useless, for the clerical part was duplicated by the casualty clerk.

To add to the joys of this position, I was bothered night after night by the telephone ringing, and asking for the wrong department. Also, it would frequently ring, and announce the fact that a man was coming over, and three-quarters of an hour later a man would leisurely arrive, with a sprained ankle. I would treat him, make out my report, and retire, when an hour or two later the phone would ring again, and the foreman would ask me what the nature of the injury was; I would answer, and then after an hour or so finally obtain sleep again. Over two hours of sleep lost for a sprained ankle! These unnecessary and false alarm calls became so frequent that I had to resort to the device of plugging the instrument. I understand that I was reported for this, and that the powers that be did not approve of it; however, my health was worth more to me than their opinion, and if a trifle like this should outweigh my hard and faithful work in their estimation it made little difference to me. My conscience is clear.

Of all the cases that I treated there was only one of unusual interest. This was a man who was caught in a crane, causing a simple fracture of the femur, and a punctured wound involving the popliteal artery, which was pumping away like the much-quoted fire hose. In spite of the fact that every department was provided with a tourniquet, there was nobody with sense enough to apply it, and the man was brought to me pretty well exsanguinated, and the stretcher that he was lying on was literally saturated with blood. I immediately applied a tourniquet, stimulated him with a hypodermic of strychnine, gr. 1/15, also gave morphine, gr. 1/6, combined with atropine, gr. 1/150, and clamped and ligated the artery through the original wound, assisted only by the laborers, who manipulated the leg, and compressed the artery at my direction. The man was then transferred to the hospital, 12 miles away, by ambulance, where he was infused. He was too exsanguinated, however, to establish a collateral circulation. Gangrene arose, requiring amputation of the extremity, and death occurred from his original shock two days later.

In regard to outside practice, there was some, of course, among the 5,000 people living in the tiny villages near the steel plant. There were three villages, the most modern being made up of new concrete houses with all modern conveniences. In this village X had his office. The other two villages were a town of about 1500, mostly made up of the older families of American people, and a town of about 2500, made up chiefly of the foreign element. Both towns were quite primitive. The people had electricity, but not gas, in the more modern of the houses. The foreigners burned oil or candles in their one-story or even two-story shacks. Pigs, cows, and geese shared the paths known as sidewalks with the humans in the foreign town. The one paved street in this town stood out in marked contrast to the cross streets, where the mud often came half-way to one's knees. As to practice, one had to build it up gradually here, as elsewhere. There was little competition, but much self-doctoring. However, I had no difficulty in obtaining a case per day during my first month of practice. For one who could live under primitive conditions, a fairly good opportunity was present here, not so good, however, as Dr. ——'s alluring letter would imply. After much looking around for an office, I finally selected the least of the evils offered, and took one in which I could at least have room enough. It was in an old building of barn-like splendor, but much needed improvements were promised by the owner in the way of running water, painting, varnishing, etc. Some of these promises were kept, such as the painting, but were considerably delayed, and the running water was not even begun two weeks after its promised completion. However, I made the best of things, and moved in just as soon as the place was at all habitable. After occupying the place for four days, I was about to enter my office, on a day when the wind was blowing a stiff gale, when the entire tin roof was blown off, landing within a few feet of me. This was too much for me, so I promptly moved out and took an office in Blankville itself.

The night work was becoming more and more strenuous as they increased the night shifts and opened new departments. Besides being aroused numerous times per night for new injuries, frequently an old routine dressing case would appear at 2 or even 5 A. M. and expect to be dressed. Of course, I refused to be imposed upon, these patients having been repeatedly told that dressing hours were from 7 to 9, but they continued to show up at these unearthly hours, and often became quite nasty when I refused to treat them. It was told to me that certain men had reported me for refusing to treat them when injured. In other words, when I refused to treat an old routine case it was reported in such a way as to appear like a new injury, and I was reported for neglect of duty. Nothing was said to me directly, but indirectly this was carried back to me. Evidently one false accusation carries more weight with people of narrow caliber than dozens of exasperatingly trying cases faithfully treated. Finally, when the strenuousness of the company work and the loss of sleep began to tell upon my health more than I cared to have it, I gave Dr. —— a month's notice, and the only comment that he made was, "Well, you are not much of a sticker!" Much of a sticker indeed! I wish that he would try it for just one week. I had made the statement to friends that no human mind ever made such a position possible. It must have been the devil himself who devised it. I also found that I had remained longer than any of my predecessors, one of whom left after about three nights of it.

I would bear Dr. —— no resentment if he had made it plain to me in his letter that the position was a night job. Of course, I would never have considered it then. Peruse his letter once more. It reads like a description of wonderful opportunities of the Golden West as found in popular novels. There are no sins of commission present, but certainly one glaring one of omission. Talk about medical ethics when one doctor thus deliberately tricks another! I wonder if Dr. ——'s conscience is clear.

In regard to charging patients who were not injured while at work, for instance, men coming in with furuncles, stomach trouble, etc. According to Dr. ——'s instructions, we were permitted to charge them. However, if the complaint was very trivial, like a headache, etc., we dispensed a few migraine tablets and did not charge. If a thorough physical examination were required, or prescriptions indicated, we would charge $1, which was fair enough,

one will agree. However, both X. and I were reported for charging for treatment, and he received a letter mentioning an instance in which I had asked for a fee and was refused, the foreman reporting me for this! We were informed that all cases must hereafter be treated free of charge. I had found that cases were too apt to be treated by the pill doctor style, tablets for every ailment known, and dispensed without either a careful history or any physical examination. For instance, abdominal pain would be treated by chlorodyne tablets, which contain morphine, gr. 1/6, and canabis indica, gr. ½. Is this up-to-date medicine? I refused to practice this sort of medicine, and studied each case carefully. However, this is a rather thankless job, when one is paid about $0.25 per case.

Before I finally left the company, X. suddenly left without notice. The details never were made clear, but as his successor was hired upon a full-time basis, it is quite evident that the superintendent objected to his spending so much time with his lucrative private practice and so little for the company, and attempted to compel him to remain at the plant all day, which he refused to do. Heretofore he had come and gone as he pleased, and left the janitor in charge, the latter being quite a skillful dresser. As X.'s private practice amounted to about double his salary, at a conservative estimate, and as his salary was only slightly larger than mine, I cannot blame him for leaving.

Lastly, a word in regard to contract practice. It might be all right when the physician is hired directly by the company, but where one man is chief surgeon and hires his own assistants out of his contract it is usually unsatisfactory. Does it seem fair that a concern as wealthy as the United States Steel Co. should pay its surgeons less than half what the United States government pays hers? Does it seem fair that a subsidiary of the Steel Trust should pay a man with two college degrees, obtained from one of the leading universities of this country, but 30 cents a day more than its lowest paid common laborers, most of whom can neither read nor write English? Perhaps other concerns are more generous, but my advice would be, do not accept contract practice unless you can conduct it from your own private office, or unless it pays sufficiently well to consider it as a full-time proposition. The lowest pay that any concern should offer its surgeons on full time should be $200 per month, as the work is very strenuous, monotonous, and uninstructive, and the social opportunities are usually nil.

154 East Seventy-ninth Street.

THE MILITARY QUARANTINE STATIONS OF HUNGARY.

By B. F. Morowitz, M.D.,

New York.

Formerly Military Surgeon in the Austro-Hungarian and Bulgarian Armies.

On my return from the European battlefields in May of this year, after being away from the United States for more than eighteen months, I was not only surprised but agreeably concerned by the many preparations being made for national defense, and as a physician the medical aspect of these appears to me as one of the most important issues. I wish, therefore, to describe as briefly as possible the system of the military observation or quarantine stations employed in Hungary along its threatened borders, for the prevention of the spread of infectious and contagious diseases into the interior of the country, trusting the idea will come under the attention of our military hygienists along the Mexican border.

Several months after the outbreak of war in Europe, the Minister of the Interior, in connection with the Ministers of War and Home Defense, ordered the construction of fourteen observation or quarantine stations in as many Hungarian towns near the Carpathian Mountains, as listed in the accompanying table.

Station	Sq. Yds. Area	Number Barracks	Number Beds	Number Physicians	Number Nurses
Munkács	96,000	26	2930	30	140
Szatmár	144,000	25	2975	20	120
Debreczen	135,000	69	5285	47	235
Miskolcz	72,000	46	4300	24	135
Besster	84,000	26	2720	14	128
Zsolna	192,000	63	4500	26	75
Rozsahegy	75,000	17	1880	15	116
Ungvár	150,000	28	3050	20	241
Satoral	93,000	47	3100	21	173
Nyiregyh	75,000	42	3200	22	210
Losone	54,000	17	1882	10	75
Nyitra	84,000	26	3000	19	130
Kassa	144,000	31	3900	22	214
Trencsén	30,000	23	1741	16	75

These towns are situated along the railroads running from various points on the battlefronts, and are connected with one another and with Budapest, the capital. They are of a fair size so that food material and other necessities can be obtained at any time.

The hospital itself is situated on the outskirts of the town, just alongside of the railroad track, and where possible adjacent to a river or stream below the town. From the main track is switched off another track to carry the Red Cross train immediately in front of the receiving barrack.

The hospital consists of a group of from twenty-five to forty-seven barracks each approximately 50 feet by 225 feet in size, or even larger, placed conveniently apart to allow for proper roadways, drainage trenches, or small tracks running between the barracks for carrying materials on small cars or hand cars. They are built of wood with cement foundations, and covered externally with rain-proof, whitewashed asbestos. In addition to the barracks holding the sick and wounded, there are barracks set aside for receiving patients, bath, kitchen,

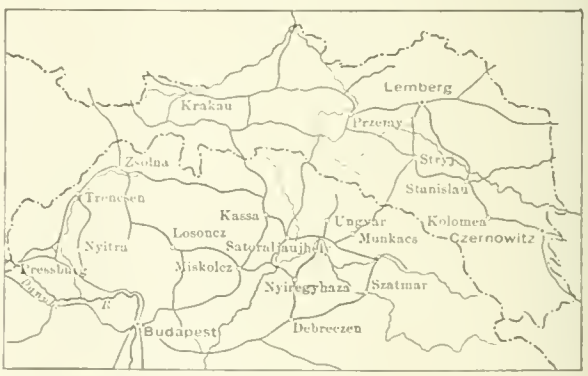

Fig. 1.—Map of Hungary showing the locations of the military quarantine stations.

power house, laundry, doctors', nurses', and employees' dormitories, general administration offices, storage, carpenter, morgue, laboratories, etc.

Each ordinary barrack, or barrack containing wounded or non-infectious sick, contains from 50

to 120 beds, one bandage room, one dining room, two diet kitchens, four toilets, two bath rooms, and two bedrooms for nurses (see diagram).

All soldiers, civilians, correspondents, etc., leaving the front for the interior must pass through

Fig. 2.—Munkacs barracks on October 2, 1915.

the required quarantine period at one of these observation stations. The object of this is the separation of all those afflicted with contagious, infectious, and even venereal diseases, with a resultant isolation strictly carried out. An exception is necessarily made in the case of troops being transported from one front to another.

The routine employed by most of the quarantine stations is as follows:

Fig. 3.—Munkacs barracks on November 20, 1915.

1. The trains are brought up to the receiving barrack and immediately emptied and disinfected.

2. The patient goes or is carried from the waiting room to the receiving room, where he gives up his military equipment such as rifle, bayonet, sword, or revolver, knapsack, uniform, boots, etc. These are placed in a bundle to which is attached the number of the admission card given to the patient. This admission card is attached around the patient's neck and later to his assigned bed.

Fig. 4.—A ward in the Munkacs barracks.

3. Then small valuables are given up, such as money, watch, medals, pocket knife, etc., which are placed in a small bag, numbered, and immediately disinfected by passing through steam, and returned to the patient when he gets through with the bath.

4. The patient is then stripped, the undercloth-ing turned in, and is taken to the barber's room, where the hair of his head, arm pits, and pubes is clipped away with electric shears.

5. Next comes the bath, a thorough scrubbing with soap, hot water, and brush, and in some stations with lysoform. After this, fresh underwear is given, with a hospital coat and cap.

6. The "inspection" doctor then examines the soldier, who is classified according to what the condition may be, and assigns him to the proper barrack.

The patients are classified in the following way: (1) Those having contagious or infectious diseases; (2) those suspected of having a communicable disease; (3) disease carriers; (4) those suffering from non-infectious diseases; (5) the wounded.

This results in the quarantine stations being divided into two great divisions, a regular hospital and an epidemic diseases hospital. The latter is separated from the former by space, and a high fence at the gate of which is placed an armed guard. The barracks of the epidemic division differ from the others, in that each one is divided into forty or fifty rooms, so that better isolation of each individual case can be carried out, no matter what the infection may be, and they are so arranged that the doctors, nurses, and orderlies coming from a patient must pass through special private bathroom

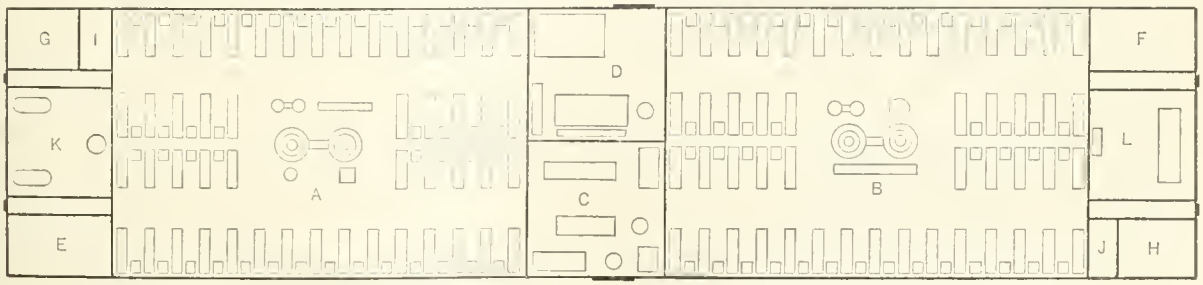

Fig. 5.—Diagram of two wards (A and B) for non-infectious cases. C, bandaging room; D, kitchen or diet room; E, F, nurses' sleeping rooms; G, H, patients' toilets; I, J, nurses' toilets; K, bathroom; L, kitchen and dining room for orderlies and servants.

before they can reach their own individual quarters. The patients in these barracks stay until cured. Iincluded in this group are the barracks containing the suspected cases. If after a period of fourteen consecutive days there occurs no development of any contagious or infectious disease, the barrack is cleared, fumigated and scrubbed with a solution of mercuric bichloride, the patients being transported to the hospital division as convalescent.

The suspected and known disease carriers are given a thorough treatment with antiseptics and diet, and after five days are allowed to leave for the interior with proper instructions as to cleanliness and personal habits.

In all other barracks, or what I have classified as the hospital division, patients who are free from fever after five days quarantine from the time of their admission, are transported toward the interior and distributed in the various base hospitals for further treatment.

In this way Hungary fights the more important enemy, Disease. It is indeed rare to find a case of typhus or cholera in Budapest, while in Vienna many of the hospitals were ofttimes full of contagious and infectious diseases, owing to the fact that Austria proper had no such system of quarantine.

By no means is the Carpathian front the only border protected with these observation stations, as there are very many of them along the southern frontier, while many are being built now along the Roumanian side. How much safer would we not be, here in New York, if our soldiers, instead of being quarantined for ten days in this city, would spend their observation period, say, at Dallas, Tex.?

ECONOMICAL, EFFICIENT, AND SPEEDY METHOD OF ADMINISTERING SALVARSAN AND SIMILAR PREPARATIONS.

By GEORGE NOBLE KREIDER, A.M., M.D., F.A.C.S.,
SPRINGFIELD, ILLINOIS.

VERY few there are who now will deny the great value of Salvarsan or its substitutes in the treatment of specific disease. This, of course, when administered intravenously in proper doses and in conjunction with the deep injection of a mercury salt in the buttocks.

Taking this for granted, it is proposed to show how the preparation may be given most effectively, safely, and economically in appropriate cases.

Preliminary Precautions Quite Necessary.—No treatment should be given without a thorough examination, and before each treatment the urine should be tested for albumin. Each patient should bring a specimen of urine in a clean bottle, which is examined in the laboratory before the treatment. Especial attention should be devoted to the examination of the heart and aorta, as lesions of these parts are frequently found in syphilitics.

Attention to Details Insures Safety.—The treatments are given once a week to a number of patients rendezvoused at the hospital. The patient is directed to come at a certain hour. An effort is made to keep the patients separated so that they may not meet each other and discuss the treatment. The hospital offers the advantage of having rooms where patients may be quickly treated should complications arise. Adjoining rooms are available, where the patient rests before leaving for home. The hospital pathologist, Dr. W. G. Bain, prepares the solution for all the cases at one time, and fills the syringe with the dose which has been decided on by me. Each dose is poured out of the entire solution into a small sterile beaker, thus avoiding any danger of commingling the doses. Practical experience proves this necessary. He sterilizes the needle after each injection. The arm, at a right angle to the body, is extended on a small sterile dressing table placed by the side of the operating table. The operator sits on a chair, with one foot resting on a footstool, and thus works easily and comfortably. The attending nurse (sister) introduces the patient to the operating room and reports on the urine test. She prepares the table for each patient, sterilizes the arm, and applies the sterile towels. She tightens the tourniquet and releases it gently when the vein is safely punctured. She takes charge of the patient after the treatment and provides a room and bed should it be found desirable. She bandages the arm after the treatment if necessary. A solution of adrenalin is kept prepared for hypodermic use in case of emergency.

Directions for Patients Taking Special Treatments.—The patients are given the following typewritten directions when they arrange to take the treatments. They serve to impress on the patient's mind the importance of the transaction and the necessity of carrying out the details:

Mr..... Date.....1916.

The treatments are given at the laboratory at St. John's Hospital each Tuesday morning between 9 a.m. and noon.

The number of treatments at the hospital will be at least six. The dates of your treatment will be.....

The day before(that is, Monday) you should take a glass of water every two hours and a teaspoonful of Epson salts at bedtime. You should eat a very light breakfast before the treatment, and lunch and dinner after treatment. A clean bottle containing urine wrapped in paper, bearing your name, should be brought to the hospital each Tuesday and given to the sister.

Soon after your treatment you should go home and rest the remainder of the day; at least sit down. Let me know of any particular bad feeling. An effort is made so to regulate the treatment that there will be no bad feeling. Sometimes it is necessary for the patient to stay in the hospital Tuesday afternoon and night.

Some member of the family should usually come with you, at least the first time.

The treatments at the office number twelve and are given Thursday, Friday or Saturday afternoon, as per arrangement. The dates of your treatments will be.....

You should take a short rest after this treatment. No need to fast before or after office treatment.

A hot bath is to be taken each day. Be careful to keep teeth and mouth clean. Let the doctor know if there is any tenderness or bleeding of gums. The cost of the hospital treatment varies with the amount of medicine given. This fee covers the amount of medicine given, the use of room, the assistance of Dr. Bain, and my services. This should be paid each Tuesday.

The Gentile Instrument Used Shortens Time of Treatment.—I believe I introduced to America the syringe made by Gentile of Paris. This I obtained in August, 1914. It revolutionized the treatment in my hands. A fairly good imitation of the Gentile syringe is made by the Becton Dickinson Company. It is made entirely of glass. The nozzle of

the syringe is placed at the lower pole, and therefore the force is applied to the piston in a direct line instead of at an angle. The needle is finished with a thumb hold and its insertion thus made much easier. I am using this syringe and with it the time of treatment is much shortened.

Economy in Numbers.—By administering the preparation to a number in one day we may use one or more of the large ampoules containing two or three grams of the drug at a saving of at least 40 per cent. in the cost of the single dose. This, of course, is a desideratum to the patient, and the surgeon, especially if he is called on to treat some charity cases.

A Schedule of Treatments Prevents Confusion.—A schedule is prepared the day before. A sample schedule for one day is given below and explains itself. It will be noticed that the initial dose is 0.2. Usually no dose of more than 0.3 is given. The exception in this table was No. 9, a husky negro, and No. 11, who received the first dose of the second series.

INTRAVENOUS INJECTIONS OF DIARSENOL (Canadian)
March 21, 1916—Service of Dr. G. N. Kreider

Name	Address	No.	Amt.	Urine	Payment	Symptoms
1—A. B.	City	3	.3	N.	Cash	Slight symptoms
2—J. O.	City	3	.3	N.	Cash	No symptoms
3—M. F.	New Berlin	1	.2	N.	Later	Pain in arm
4—W. D.	City	5	.3	N.	Later	No symptoms
5—R. D.	City	5	.3	N.	In full	No symptoms
6—L. A.*	City	5	.3	alb.	In full	No symptoms
7—M. L.	Waverly	3	.3	N.	Pd.	Some nausea
8—R. L.	City	3	.3	N.		
9—C. M.	City	1	.3	N.	Guarnt.	No symptoms
10—M. H.	Mechanicsburg	2	.3	N.	Pd.	No symptoms
11—W. B.†	City	1B	.3	N.	Pd.	No symptoms
12—C. N.	Edinburg	3	.3	N.	Pd.	No symptoms
13—M. H.	City	2	.3	N	Pd.	High fever
14—M. W.	City	1	.3	N.	Pd.	No symptoms
15—M. P.	Chicago	5	.3	N.	Pd.	No symptoms
16—A. C.	Hillsboro	4	.3	N.	Pd.	No symptoms
			4.6			

* This patient was given 12 intravenous injections notwithstanding the presence of albumen in the urine. There were no disagreeable symptoms.
†This second series of treatments is indicated by the letter B.

Time Required.—We estimate that the time required for each treatment averages fifteen minutes. Of course, the actual time required for injecting the 60 to 90 c.c. in the vein after it is safely punctured is very short, but there is always some time required for getting the patient into the room, arranging the table, preparing the arm, and caring for the patient after the treatment.

Concentrated Solution Always Used.—The preparation has been given by me for two years in concentrated solution. In all this time, embracing more than 600 injections, there has been no symptom that could be attributed to this method. This plan, therefore, is safe for the patient and enables the surgeon to treat cases much more rapidly than when 300 c.c. of solution is used according to the old method advocated when the remedy was first introduced. I used the old plan for three years, but would not return to it.

Modern Methods Eliminate Disagreeable Symptoms.—When the intravenous injection of salvarsan was first introduced, nausea, vomiting, diarrhea, and more or less fever was the rule, but with such a plan as is above outlined it is the exception. Since using the Gentile syringe and needle the difficulty of puncturing the vein and injection of the solution has been nearly abolished. I have had but two bad arms in two years.

522 CAPITOL AVENUE.

A STUDY OF THE NEWER PHYSICAL SIGNS IN THE DIAGNOSIS OF EARLY PULMONARY TUBERCULOSIS.

BY MAX GROSSMAN, M.D.,
BROOKLYN, NEW YORK.

WHILE different observers[1,2,3,4] have been busy in research work in the laboratory studying pulmonary tuberculosis from every possible angle in the endeavor to facilitate early diagnosis and thus render possible early treatment, clinicians have not been idle, and have faithfully done their share in the studying of physical signs and phenomena, enlarging our scientific knowledge and proving of service to humanity.

As shown by previous articles of the writer,[5,6,7] one of the earliest effects of the tubercle bacillus is its effect on the heart. No sooner does the tuberculous process become active than the heart dilates, manifesting itself in a rapid pulse of weakened quality.

At the same time a phenomenon takes place in the heart which cannot be overestimated as to the value of its recognition; the writer refers to pulmonary accentuation.[11]

Pulmonary accentuation means that the pulmonic second sound is louder at the second left pulmonic interspace than at the second right aortic interspace. This is abnormal in adults and when obtained is of value in connection with other signs. An interesting point about this and one which the writer has not seen emphasized before is the fact that pulmonary accentuation may persist for a long time even after the tuberculous process has healed or become arrested, and may be the only physical sign remaining of a previous tuberculous pulmonary infection.

It is well to remember, and this is a fact not mentioned by the writer in his previous articles on the subject, every once in a while dilatation of the heart may persist even after the case has become arrested. The value of these points cannot be overestimated. It has been shown, time and again, that what appears to be an early pulmonary tuberculosis is really an old process showing an exacerbation and simply, as it were, breaking out again. If this last statement be borne in mind, it can be readily appreciated that any sign or group of signs which is helpful and assists us in coming to a conclusion regarding the existence of a previous tuberculous infection is of great aid in guiding us as to the possibility of present infection.

Now, let us go to the pulmonary apices, the headquarters as it were, and see what information new in character has been learned in the study of diagnosing early pulmonary tuberculosis.

First in its great clinical importance let us take up the sign popularized by Dr. Robert Abrahams[8] and now known to clinicians generally as "Abrahams' Acromion Auscultation." This exceedingly valuable sign, which was later additionally studied by Nathan Magida,[9] Frank A. Bryant,[10] and others, is of the greatest help in detecting the earliest manifestations of tuberculosis in the apices. Acromion auscultation may persist for some time, even after the process is no longer active, and in such cases it would tend to show the existence of a previous infection. In this connection the writer has noticed the following, which he has not heard mentioned before and which he believes is of great value in many cases in distinguishing a recent infection from a previous one: When râles are heard on auscultating the acromion process this would most

likely show recent infection, certainly an active condition. When râles are not heard, simply a prolonged expiration or abnormal whispered sound, this would most likely indicate a chronic condition —that is an old tuberculous process.

Surface temperature mentioned years ago in von Ziemssen's "Cyclopedia of Medicine" in relation to scrofulosis was adopted and elaborated by Abrahams[11] in the detection of incipient pulmonary lesions. The writer has noticed the following interesting phenomenon in connection with the same: While a higher temperature than normal at an apex is followed by acromion auscultation, the opposite proposition does not hold good; that is to say an apex showing abnormal acromial breathing may not show any abnormal surface temperature. It is well to remember, moreover, that both abnormal acromial breathing and surface temperature are rarely present in advanced pulmonary tuberculosis. The reason for this being no doubt the ulcerative changes taking place, when the destruction of lung tissue gives the acromion process no opportunity to transmit the atypical respiratory sounds, and probably results in there being little or no hyperemia present at the apex in this unfortunate stage.

In conclusion the writer would state that since the finding of the tubercle bacilli in the sputum no longer shows an early lesion it behooves the conscientious diagnostician to master the other methods of diagnosis so that he may be able with reasonable certainty to tell when an incipient lesion is present. Aside from the scientific interest attached to the study of new phenomena which are now gradually becoming better understood, the writer believes time spent on the comparatively newer signs enumerated in this article will repay the careful student and open up a field which offers many possibilities in its scope and further elaboration.

In this connection much credit is due Dr. Robert Abrahams, who by his teachings and writings has helped to place the subject of diagnosis of incipient pulmonary lesions on a basis which affords opportunity for earlier recognition and hence greater benefit to the afflicted patients.

Simulation of Albuminuria. — One of the ingenious methods employed by malingerers in the present war is the simulation of albuminuria by the injection of white of egg into the bladder. The detection of this is difficult, although it is asserted that a mixture of acetic acid and formol will precipitate the egg albumin; the urine is then filtered and tested for pathological albumin.—*Lyon Médical.*

Medicolegal Notes.

Prescriptions for Intoxicating Liquors.—The Missouri statute, Revised Statutes, 1909, Section 5784, declares that any physician who shall make any prescription to any person other than for medicinal purposes shall be deemed guilty of a misdemeanor. Section 5781 provides the character of prescription which will protect a druggist in making sales of intoxicants in quantities of less than four gallons. A physician who unlawfully issued a prescription for intoxicating liquor wrote it in such a manner that the druggist who filled it was not protected; it was not dated, and it did not state that the intoxicating liquor was prescribed as a necessary remedy, though it stated it was "prescribed for medical purpose only." The Springfield Court of Appeals, State vs. Nicolay, 184 S. W. 1183, held that the "physician was nevertheless guilty of a violation of Section 5784; the word "prescription" as used in the statute meaning a direction of remedy or remedies for a disease and the manner of using them, and not necessarily a valid prescription which would protect the druggest who filled it.

Evidence in Poisoning Case.—On the trial of a man for the murder of his wife by poison with morphine or laudanum it was held proper to admit evidence (1) of a physician who made the postmortem examination that the condition of the brain and blood led him to suspect poison; (2) of a chemist, that a jar handed him contained a liquid "said to be the stomach contents" of one whose death was attributed to poison, where the liquid was proved by witnesses from whom the chemist received his information to be what it was said to be; (3) of a chemist who had examined the contents of the deceased's stomach, as to the quantity of morphine or laudanum that was likely in the system of the deceased or in the stomach prior to death; (4) to show the defendant's relations with another woman and his effort to resume sexual relations with her after his wife's death; (5) that there was a lack of any appearance of grief on his part at his wife's death; (6) of an expert witness as to what portion of 4 grains of morphine or opium would likely be absorbed through the system.—State vs. Crivelli, New Jersey Court of Errors and Appeals, 98 Atl. 250.

Concealment of Nature of Malady.—The fact that a physician concealed from a parent that a child had diphtheria which resulted in death does not tend to show lack of skill or reasonable care in treatment.—Hoover vs. Buckman, 194 Ill. App. 308.

False Answer in Insurance Medical Examination.—The false answer in an application for life insurance as to having consulted a physician within a specified time before the date of the medical examination, the applicant having warranted that his answers were true and having agreed that if the answers were untrue all rights to himself or to his beneficiary should be forfeited, is a bar to recovery on the benefit certificate issued.—French vs. Modern Woodmen of America, 194 Ill. App. 438.

Medical Evidence of Misbranding.—In a proceeding to forfeit drugs as being misbranded under the Food and Drugs Act there was evidence that the drugs were stated to benefit locomotor ataxia. In support of its case the Government called several witnesses, physicians of proven ability, knowledge, and experience, who testified that the pill would not, and why it could not, have any beneficial effects in locomotor ataxia and the other diseases named, partial paralysis, sciatica, etc. They also testified that medical opinion was unanimous in so saying. It was also shown, and all of this without contradiction, that the pill was practically the well-known Blaud pill, used generally in medical practice. It was complained, however, that the testimony of these witnesses was not competent, being a mere expression of their personal opinions or views. But the Circuit Court of Appeals, Third Circuit, held that the case was wholly different from one where witnesses were testifying to their personal views upon a controverted question of opinion. The testimony here was of fact, namely, that there was general, uncontroverted consensus of opinion. For example, referring to the effect of the pills, the proofs were that they were utterly useless for locomotor ataxia; that, so far as the witness knew, there was no difference in medical opinion on that point, nor on the point that there is no combination of drugs known to medicine, which can be compressed into one pill, that could possibly exert a beneficial effect on all the various troubles named.—Eleven Gross Packages, Etc., vs. United States, 233 Fed. 71.

ANTIDOTES IN MERCURIC CHLORIDE POISONING.

THE popularity of mercuric chloride as a means of suicide has led to the proposal of a large number of substances as antidotes to its poisonous action. Many of them have been tried from time to time but generally without much effective result. The desirability of determining the relative value of these substances led Fantus to undertake an experimental study of their effectiveness on animals which had received a fatal dose of the drug. His report (*Jour. Lab. and Clin. Med.*, 1916, i. 879), makes very interesting reading. He first established the fatal dose of the drug for rabbits and determined the average length of life of the animals after they had been poisoned. He then determined the influence of the various antidotal measures when applied at the time the poison was administered or subsequently. He was able to show that dilution had no effect aside from a mitigation of the local lesions and that albumin, the standard antidote, was unable to prolong the life of the poisoned animal except when given at the same time as the bichloride. Sodium bicarbonate, sodium acetate, and stannous chloride each had a certain amount of antidotal effect and might be expected to be of some use, though not very reliable. He was able to obtain much more favorable results with the use of Carter's antidote which consists of three parts of sodium phosphite and two of sodium acetate. This was efficacious in greatly prolonging the life of the poisoned animals even when it was given after the administration of the sublimate. A substitution of sodium hypophosphite for the phosphite gave results that were quite similar though perhaps more uniform. His best results were obtained with an antidote composed of one part of sodium hypophosphite and five parts of hydrogen peroxide. This combination of a reducing and an oxidizing agent has no chemical justification but his results were uniform and he suggests the explanation that the peroxide acts as a catalyzer.

Fantus is careful to say that the eliminative treatment which has met with such success at the hands of Lambert and Patterson should not be neglected merely because an apparently efficient antidote has been found. The excellent results were obtained by those investigators without any such antidote but it is reasonable to believe that such chemical treatment might at least hasten the time of recovery. The author advises that if the amount of poison taken is known, the amount of hypophosphite used shall be ten times the amount of bichloride taken. As this dose might itself be poisonous it would be wise to wash the stomach thoroughly, after giving it, with a very dilute solution of the antidote and a safe dose could be left in the stomach. It is very gratifying that such information is now at our command and the mortality from sublimate poisoning should be much lower in the future than it has been in the past.

THE GASOLENE TROUBLES OF ENGLISH PHYSICIANS.

WE who grumble at the soaring price of gasolene little realize what real trouble is. Across the sea our English cousins are not only obliged to pay a greatly increased price for gasolene, or petrol as it is usually called there, but they have difficulty in getting enough for the legitimate needs of their practice and its sale is hedged about with so many restrictions that a British doctor never knows when he will break the law. Several factors, all due to the war, are responsible for the dearth of gasolene in England. One is the fact that a large quantity is required for the troops,—for their motor ambulances, motorcycles, aeroplanes, etc. Another is the actual decrease in the importation of petroleum due of course to the diversion of oil shipped to safer waters. A third factor is the shortage of metal containers, metal being in great demand for military purposes.

In view of these facts the English authorities have placed the supply of gasolene under their control and have definitely restricted the amount which may be issued, these restrictions being most stringent on cars used merely for pleasure and growing less so as the use of these cars is more and more necessary, the most deserving car user being justly considered the physiciain. A committee was accordingly appointed by the President of the Board of Trade early in the spring to control the supply and distribution of gasolene and to consider what measures are necessary to the national interest "(1) to ensure that adequate supplies of gasolene shall be available for the purpose of war and for other essential needs, and (2) with the above object to regulate the use of gasolene for other purposes in the United Kingdom during the period of war; and subject to the direction of the Board of Trade, to give executive effect to the measures decided on." This committee divided gasolene users roughly into three classes: The first class included doctors and government officials engaged in business such as that of police, the second class embraced all other consumers including those who maintained cars or motorcycles for pleasure.

It was not thought at first that it would be necessary to restrict any reasonable demands of the first two classes, but this view had to be modified later. The amount of gasolene used by the troops in the field at first equaled and later exceeded the amount used by the entire United Kingdom before the war. Upon representation of the British Medical Asso-

ciation the committee made arrangements so that the wants of physicians should be supplied in priority to nearly all other users. The moderate restrictions at first placed upon the use of gasolene were soon found inadequate, and on August 1 it was made impossible to purchase gasolene without a permit from the Petrol Committee of the Board of Trade. Permits were issued for not more than six months' supply, the duty (six cents a gallon) had to be paid at the time of issuance of the permit. In some cases medical men for some unknown reason were not allowed as much for the six months to come as it was shown they had actually used in their practice for the six months just passed. This was taken of course with bad grace by the doctors and the British Medical Association was stirred to action. The Petrol Committee finally decided to grant them the amount requested up to the maximum of fifty gallons per month; as this is only one and two-thirds gallons per day, or an amount sufficient to run a car from fifteen to thirty-five miles, it can readily be seen that it must fall short in many cases of heavy practice, especially in view of the shortage of physicians and the extra work imposed on the remaining ones.

The English medical periodicals have accordingly been full of letters from subscribers protesting about this situation and grumbling in true British style. It appears, however, in cases which the British Medical Association has investigated, that failure of a medical man to be supplied with sufficient gasolene has nearly always been due to some neglect on his part,—delay in presenting his demand, or failure to notify his local garage in time of the amount that he required. As the Board of Trade has adopted the policy of giving the medical profession the gas over all other users it would seem that with reasonable care it should not suffer greatly unless indeed the entire supply of the country is cut off.

MULTIPLE TYPHOID.

That a number of different bacteria may give rise to the same symptom has long been recognized, and typhoid fever is known as a plurispecific disease of this character. It is much less understood that several infections may coexist, and that one kind may succeed another, thus simulating a relapse or reinfection. Many striking facts have recently been made public showing that a simultaneous infection with two or more specific germs is very seldom succeeded by a relapse or new infection. Typhoid fever from a single germ naturally exhibits a typical course and temperature curve, and gives positive agglutinative and blood-culture tests. Multiple typhoid is not more severe than single typhoid. Atypical typhoid must often be due to double or multiple infection. When true relapse follows a pure typhoid it means that the original infection has been arrested temporarily, only to break out anew. But in many cases the relapse means that a patient convalescing from simple typhoid has become infected by a second form of the disease; that is, the condition of the intestine after simple typhoid makes it fall a ready prey to one of the paratyphoids.

Double or multiple typhoids show an atypical and intricate course, but agglutination and blood-culture tests supply the positive evidence. When a subject develops typhoid some months or years after a first attack, it may mean that the immunity is lost, or that the patient falls a victim to a second form of the disease. Especially significant are all of these facts for the efficacy of protective vaccination. In theory at least, the serum used should be polyvalent to the extent of comprising the products of all three of the causes of typhoid. This was first proposed by Castellani, and the plan has been tested widely in several countries, notably by Chantemesse of France, who began its systematic use in 1915 among soldiers and marines.

Very recently, Grimberg has published (under the auspices of Chantemesse) a study of 160 cases of typhoid in various Paris hospitals, in a pamphlet entitled "Les Typhoïdes Intriquées." The work is extremely technical, devoted almost wholly to agglutination and other serum tests and blood-culture finds in the various single and multiple infections and the pseudorelapses and pseudoreinfections, in both vaccinated and non-vaccinated subjects. The chief point upheld throughout is that mixed or polyvalent vaccine is a completely scientific as well as practicable idea. The author believes that progressive infection is more common than unique infection, because one attack, even if it furnish immunity to a second infection of the same sort, almost necessarily furnishes the occasion for infection by one of the other diseases. This preponderance of mixed or progressive infection makes necessary the routine use of a triple vaccine.

COLLECTION AND DISPOSAL OF DOMESTIC WASTES.

There is little doubt, in fact, it is not even a matter for argument that the proper disposal of sewage of every description bears a very definite relationship to disease and mortality. Unsanitary conditions and ill health and high death rates are synonymous terms. Where sewage is got rid of in such a way that the germs of disease are not spread broadcast, there good health prevails and obviously the reverse is the case. No more conspicuous examples of the influence upon health of good sanitary conditions have ever been afforded than the result of effective sanitation in the European war. It has now been going on for longer than two years under conditions seemingly most prone to spread disease yet there has been no widespread epidemic on any front, with the exception of typhus fever in Serbia. But there is no need to elaborate the argument that thorough sanitation is essential to good health and the point which it is desired to emphasize is that domestic sanitation is often very defective and is a fertile means of disseminating infection. The proper disposal of domestic wastes is a problem which has not yet been solved, or rather it might be said that it is very frequently neglected. In the *Canadian Practitioner and Review* September, 1916, F. A. Dallyn writes on the subject and draws attention in particular to the menace of the privies and especially of the unscreened privies. He shows that in the better educated parts of

Canada statistics prove that the infant death rate is very considerably less than in some of the other centers and that where there are a good water supply and sewerage system both the infantile mortality and the death rate from typhoid fever are low.

It is not only in the country districts that the menace of the unscreened outside closet exists; in the suburban parts of many American cities it is present and even the environs of New York are not free from the opprobrium of allowing such a survival of the dark ages to continue. Where there is a privy it should, at least, be screened so that flies cannot gain access to it and carry the germs of disease far and wide. It is a scandal of the first degree that outside closets should be permitted in the neighborhood of large modern cities. Up to date sewerage plants should be established wherever possible and in any event, as Dallyn points out, proper means should be instituted for the collection of domestic wastes. By so doing the interests of public health and particularly of infants' health will be best served. Ignorance as to the means of preventing many diseases can no longer be pleaded.

Psychoanalysis.

Although Freud has not a few followers among the English-speaking members of the medical profession, speaking generally his theories have excited a considerable amount of repulsion in Great Britain. Granted that many of his conclusions are based on a sound foundation and that the sexual element does enter largely into the question of neurosis, yet the manner in which Freud and his disciples introduce sexuality into all the acts and pleasures of life and claim that analysis will bring forth the fact that repressed sexual desire is responsible for the neurotic tendencies exhibited by so many civilized persons has aroused repugnance and some disgust. Dr. Agnes Savill, in the *Medical Press*, May 17, 1916, voices the opinion of a large proportion of the medical profession when she says, "So unanimous a repugnance has in all probability a healthy cause, and points to a deep-rooted confidence in the innate righteousness of human nature which seems assailed by this recent school of psychologists. The common sense of the common man rises against the conclusions of Freud, which strip humanity of dignity and beauty." Savill draws attention to the fact that there is another school of practitioners of the new psychology whose home is in Zurich and whose high priest is Dr. C. G. Jung. This school is not so well known as that of Freud, owing partly to the fact that its publications have not been translated so freely, and partly, no doubt, because the very boldness and novelty of Freud's view have brought worldwide publicity. Jung is not blind to the sexual origin of many neuroses, but the place he attributes to it is very different from that of the Viennese school. According to Savill the Viennese school seeks the meaning of man in his primitive sexual roots; the Zurich school looks at the flowering branches of man's social activities and aspirations. Savill ends a strong article with a warning to employ the greatest care in the choice of an operator employing psychoanalysis, saying that "no protest that influence is not consciously used will convince us that the choice of the analyst is not more important than the choice of a surgeon. The clumsy knife may maim or slay the body; injury to the soul is of infinitely greater moment."

Gunshot Wounds of the Rectum.

As a rule, the injuries received during the present war have been wounds of the upper extremities, and especially of the head. These results have been due, of course, to the trench warfare, the head and upper parts of the body being less well protected than the lower parts. However, injuries of the lower extremities are by no means infrequent, and in a paper read recently before the Royal Society of Medicine of London, P. Lockhart Mummery discussed gunshot injuries of the rectum. In the first instance, it is the experience of surgeons at the front that in wounds of the rectum there is a considerable amount of suppuration, and that it always is difficult to control sepsis in these cases. In fact, such wounds are generally of a serious nature. Mummery, who is at a hospital in London, does not treat these cases until it is no longer a question of saving life or controlling sepsis but of dealing with the deformity produced by the healing or part healing of the wounds. It is pointed out that no attempt should be made to close wounds of the rectum while there is sepsis. One should wait until healing has occurred before doing any operation to close the opening. Mummery believes that all such openings into the rectum can be closed successfully if sufficient care be taken, always providing that enough of the anal musculature has been left to secure a functional result. A very striking fact in connection with these wounds is that the results are in many cases extremely crippling. The size of the wounds, particularly where some portion of the bony pelvis has been struck, coupled with the fact that almost without exception the wounds have suppurated violently, results in fearful cicatrization which causes serious stricture and contraction of the parts, more particularly if the anus is involved. As a rule, bullet wounds of the rectum cause serious injury to the bladder or other structures in the pelvis, and sepsis in the surrounding tissues with frequent abscesses gives trouble for months after the rectal wound has healed.

News of the Week.

Report on Poliomyelitis Epidemic.—An interesting summary of the recent poliomyelitis epidemic in New York has just been issued by the Department of Health. The total number of cases placed under quarantine by the department up to and including October 11 was 9,177; of these, however, 250 cases were found, after careful clinical study, not to be poliomyelitis, so that the total of true cases was 8,927. The total number of deaths recorded by the department was 2,343, giving a case fatality of 26.24 per cent. The department divides these cases into three classes, the first consisting of those treated in the hospitals of the department, the total number of these being 4,474, with 653 deaths, a case fatality of 14.59. The second group consists of 2,663 cases admitted to twenty-seven other hospitals in the city; among these there occurred 387 deaths, a case fatality of 14.53. The third group includes those cases treated in the home, because (a) home conditions were adequate for isolation

or (b) the patients were too ill to be removed, or (c) because the cases were not reported to the department until the death certificate was presented. This group numbered 2,040 cases and the deaths totaled 1,303, giving a case fatality of 63.87. The high percentage of fatality in this group is largely due to the fact that the major portion of the cases comprised in it were of the severest type. The department reports that up to September 30 a total of 16,267 cases of supposed poliomyelitis were reported by physicians, nurses, and members of various households, and that of these only 8,630 proved to be true cases. From August 21 to October 13 there were discharged from the hospitals of the Department of Health, 2,053 cases; of these 66 per cent. showed paralysis of some degree; in 18 per cent. the paralysis had wholly disappeared, and 15 per cent. had not shown any paralysis at any time during the course of the disease. The after-care work in the homes has shown that of 2,715 cases, 1,865 show a severe paralysis of one or both legs, so that the children are unable to walk; 530 more were partially paralyzed in the legs, but were still able to walk, and 273 had one or both arms totally paralyzed. The department estimates that between 75 and 80 per cent. of the cases with persistent paralysis will fall in the class of persons usually obtaining medical services free through dispensaries or hospitals.

Report on Poliomyelitis.—The Committee of the American Public Health Association, appointed to report upon the subject of poliomyelitis, has submitted its findings, of which the following is an abstract: The specific cause of poliomyelitis is a microorganism, a so-called virus, which can be positively identified at present only by its production of poliomyelitis in monkeys experimentally inoculated. This virus is present in the nerve tissues and certain other organs of persons dying from the disease, and in the nose, mouth, and bowel discharges of patients suffering from the disease. It has also been shown that healthy associates of poliomyelitis patients may carry the virus in their noses and throats. These findings, together with the fact that monkeys have been infected by direct application of the virus to the mucous membrane of the nose and by feeding of the virus, and strong evidence that infection may be directly spread from person to person. The fact that contact between recognized cases can seldom be traced may be explained by the lack of means for detecting mild, non-paralytic cases and by the belief that healthy carriers of the virus and undetected cases are considerably more numerous than the frankly paralyzed cases. Many facts, such as the seasonal incidence and rural prevalence of the disease, have seemed to indicate that some insect or animal host, as yet unrecognized, may be a necessary factor, but specific evidence is lacking, and the weight of present opinion inclines to the view that poliomyelitis is exclusively a human disease and is spread by personal contact, whatever other causes may be found to be contributory. Personal contact includes the possibility of infection by the transference of body discharges from one person to another and of infection through contaminated food. The incubation period, though not definitely established, is believed to be less than two weeks and probably in the great majority of cases from three to eight days. For the control of the disease, the employment of the following administrative procedures is demanded. (1) The requirement that all recognized and suspected cases be promptly reported. (2) The isolation of patients in screened premises. The duration of infectivity being unknown, the period of isolation must necessarily be arbitrary, and six weeks has been recommended and generally accepted. (3) Disinfection of all body discharges. (4) Restriction of the movements of intimate associates of the patient as far as possible, including at least exclusion of the children of the family from school and other gatherings. (5) Protection of children as far as possible from contact with other children or with the general public during epidemics. (6) Observation of contacts for two weeks after the last exposure. There is no specific treatment of established value in poliomyelitis, but during the persistence of the acute symptoms, rest in bed, symptomatic relief, and passive support for the prevention of deformities are necessary. Active measures during this stage may cause serious and often permanent injury. Hospitalization of patients where possible is to be encouraged. The best chances of recovery from residual paralysis demand skillful after-care, often long continued, and always under the direction of a physician familiar with neurological and orthopedic principles of treatment.

Caring for Paralysis Victims.—The Post-Graduate Hospital, New York, has recently opened a department for the care of children on the lower East Side who have recovered from infantile paralysis. The latest appliances used in the after-treatment of the disease are being installed, and four masseurs and two nurses have been assigned to the work. The New York Committee on After-Care of Infantile Paralysis Cases is forming plans for the centralization of all this after-care work into one organization to look after all the children discharged from hospitals, and to provide for the training of nurses especially for this work and the laying out of the city in districts in order that the work may be carried on systematically. Dr. Holt, it is reported, has estimated that there are between 4,000 and 5,000 children in the city who because of paralysis will have to be cared for this winter and through the next year; in many cases provision will have to be made for the child's future, as very few of those seriously crippled recover permanently. The New York Association for Improving the Condition of the Poor has formed a special committee on after-care of infantile paralysis in New York State, outside of New York City. The association will cooperate in this work with the State Department of Health. Under the auspices of the latter a series of clinics is being held in various places throughout the State.

Health Supervision of School Children.—In support of the 1917 budget estimate of the Bureau of Child Hygiene of the New York City Department of Health, the Bureau of Welfare of School Children has issued a memorandum in regard to the proposed expenditures. The appropriation asked for is $17,240 in excess of that received last year, and it is explained that the additional money is needed for the enlargement of the staff of medical inspectors and nurses and the employment in addition of six dental hygienists. If the money is available it is proposed to employ 125 medical inspectors instead of 100 as at present, and 252 school nurses instead of 200. The reports on medical inspection during 1915 show that out of 925,000 pupils enrolled in the public and parochial schools, only 305,665 or 33 per cent. were examined for physical

defects, and that of those so examined 222,072 or 72.6 per cent. had physical defects requiring treatment. It may be assumed that an equally large percentage of the children not examined were suffering from various defects which were a handicap in their school work. Under the Education Law of the State of New York the employment of physicians to examine each public school child each year is made mandatory outside of New York City; in the city, under the present system, each child is examined but once in three years, and this is due to the fact that with the existing staff of physicians 9,200 pupils are assigned to each, while each nurse is supposed to care for 4,800 pupils. As a result not only is the medical inspection inadequate, but the follow-up work of those cases found to need attention in the homes is ineffective. For the first time an appropriation has been asked to provide for the employment in the schools of dental hygienists, the value of whose services has already been demonstrated in several cities outside of New York. The large percentage (63.9) of children with defective teeth in the public schools, and the fact that more than half of these children are probably too poor to patronize private dentists, offer the most convincing proofs of the need for such prophylactic treatment as the dental hygienists are fitted to give.

Proposed Abolition of Heroine.—A meeting of the Committee on Drug Addiction of the National Committee on Prisons was held at the Hotel Vanderbilt, at which, besides the chairman, Dr. Simon Baruch, were present Drs. Samuel W. Lambert, Frederick Peterson, Frederick Tilney, ex-Surgeon-General Charles F. Stokes, Mrs. Helen Hartley Jenkins, chairman of the Committee on Social Hygiene, and Mr. Joseph D. Sears, secretary, ex officio. Discussion revealed a consensus of opinion that heroine is, among drug addicts, most prevalent among boys and in the early decades of adult life, and therefore the chief promoter of vice and crime. In view of this fact resolutions were adopted stating that since heroine is not so indispensable a drug that its place cannot be easily taken by other drugs and measures that do not menace public welfare, the committee recommended federal legislation to prevent the importation, manufacture, and sale of heroine.

Montefiore Home.—The new private pavilion of the Montefiore Home was opened for inspection on November 6, at which time the annual meeting of contributors was held. The funds for the pavilion were obtained entirely by private subscription and no expense has been spared to make the hospital one of the most complete of its kind in the world.

Street Accidents.—The National Highways Protective Society reports that during the month of October, 54 persons were killed by vehicles in the streets of New York City; for the same period the Police Commissioner reports a total of 59 deaths from the same cause. In the State outside of New York City, 38 persons were killed by vehicles during the month, while in New Jersey 27 met death in the same way.

New Public Health Association.—The committee appointed at a recent conference of the health officers of Connecticut to consider the plan of forming a public health organization in the State, has reported favorably, and the preparation of a constitution is now under way. Dr. C. J. Bartlett of New Haven, has been put in charge of the arrangements for organization, and the first meeting will be held in that city on December 6. The society will be called the Connecticut Public Health Association, and will work along the general lines of the American Public Health Association.

Personals.—Dr. William Sharpe, professor of neurologic surgery in the New York Polyclinic Medical School, spoke on "Recent Advances in Brain Surgery," before the College of Physicians of Pittsburgh, Pa., at a dinner at the University Club on October 27. The talk was illustrated by moving pictures.

Gifts to Charities.—The White Plains Hospital Association is the residuary legatee under the will of the late Mrs. A. C. Foulds of White Plains, who died recently.

Mr. William Bell Wait of New York, widely known as an educator of the blind, who died recently, left an important valuable bequest to the public. Mr. Wait's will provides for the free use of his several inventions, thirteen in number, made for the purpose of reducing the cost, increasing the durability, and enlarging the amount and scope of literature for the blind in the New York point system. The decedent gave all his books relating to the blind to the New York Institute for the Education of the Blind, of which he was principal for many years.

Discussion on Poliomyelitis.—At a meeting of the New York Neurological Society to be held at the Academy of Medicine, Tuesday, November 14, at 8.30 P. M., the subject for discussion will be "Poliomyelitis: Its Diagnosis and Treatment, and the Management of the Recent Epidemic." Papers will be read by Drs. W. M. Leszynsky, Frederick Tilney, B. Sachs, and C. L. Dana.

Gifts for Dental School.—Columbia University, New York, has announced the receipt of two gifts, amounting to $125,000, from anonymous donors, to be used toward the establishment and endowment of the new dental school. Officially the dental school has opened at the University, but the actual dental courses will not begin for two years. Students entering upon the study of dentistry at the University must first spend two years at the College of Physicians and Surgeons, specializing in dentistry for the next two. The dental school is thus really a graduate school, the only one of its kind in the country.

Ambulances for Paralysis Victims.—Three ambulances, one each to be used in Manhattan, Brooklyn, and Boston, in transporting children recovering from infantile paralysis between their homes and surgical clinics, were assembled in City Hall Park, New York, on October 31, to be dedicated and to receive the good wishes of the Mayor. The ambulances were purchased and will be maintained by the Militia of Mercy.

New Medical Library.—The New York Medical College and Hospital for Women, New York, has received a gift from Mr. M. W. Dominick of a medical library, which will be endowed by Mr. Dominick as a memorial to his son, Dr. George Carleton Dominick, who died recently.

Obituary Notes.—Dr. EMORY G. DRAKE of Brooklyn, N. Y., a graduate of Long Island College Hospital, Brooklyn, in 1874, died at his home on October 29, aged 64 years.

Dr. THOMAS J. MORTON of Philadelphia, a graduate of the Jefferson Medical College, Philadelphia, in 1885, for twenty-five years physician to the coroner's office, and for many years a member of the Common and Select Council, died at his home on October 12, aged 52 years.

Dr. Daniel Newton Mason of Suison City, Cal., a graduate of the National University of Arts and Sciences, Medical Department, St. Louis, in 1879, died at his home on October 4, aged 73 years.

Dr. Hawley Nathan Barney of Richmond, Cal., a graduate of the University and Bellevue Hospital Medical College, New York, in 1900, and a member of the American Medical Association, the Medical Society of the State of California, and the Contra Costa County Medical Society, died at the Napa State Hospital, Napa, Cal., on October 7, aged 39 years.

Dr. Harry C. Weber of Louisville, Ky., a graduate of the Kentucky School of Medicine, in 1898, and a member of the Kentucky State Medical Association, the Jefferson County Medical Society, and the American Urological Association, died at his home, from uremic poisoning, on October 6, aged 46 years.

Dr. Stockbridge P. Graves of Saco, Me., a graduate of the New York Homeopathic Medical College and Flower Hospital, New York, in 1861, died at his home on October 12, aged 90 years.

Dr. William S. Allee of Olean, Mo., a graduate of the Missouri Medical College, St. Louis, in 1875, and a member of the American Medical Association, the Missouri State Medical Association, and the Miller County Medical Society, died at the Wesley Hospital, Kansas City, on October 9, aged 64 years.

Dr. L. Dann of New York, a graduate of the New York University Medical College, New York, in 1885, died suddenly at his home on October 20.

Dr. William G. Dubois died of uremia at Camden, N. J., on October 28 at the age of 59 years. He was graduated from Hahnemann Medican College and Hospital in the class of 1880.

Dr. Peter J. McCahey died at Philadelphia on October 22 at the age of 60 years. He was graduated from Jefferson Medical College in the class of 1885.

Dr. George Lesser of New York and Brooklyn, a graduate of New York University Medical College in 1897, died at his home on October 22, aged 46 years.

Dr. William J. Coppernoll of Newark, N. Y., a graduate of the University of Michigan Medical School, Ann Arbor, in 1887, and a member of the Medical Society of the State of New York and the Wayne County Medical Society, died in Laconia, N. Y., on October 14, after a long illness.

Dr. Clarence A. Rogers of Cordova, Tenn., a graduate of the Memphis Hospital Medical College, Memphis, in 1903, of the Medical Department of the University of the South, Sewanee, in 1906, and of the Vanderbilt University, Medical Department, Nashville, in 1907, died suddenly at his home on October 10, aged 38 years.

Dr. Hayden Austin West of Sewanee, Tenn., a graduate of the University of Tennessee, College of Medicine, Memphis, in 1899, and a member of the Tennessee State Medical Association and the Franklin County Medical Society, died on October 8, aged 38 years.

Dr. Joseph H. Brewer of Salem, Ore., a graduate of the Northwestern Medical College, St. Joseph, in 1881, died recently at his home, after a year's illness, aged 69 years.

Dr. Benjamin F. O'Daniel of Denver, Colo., a graduate of the University of Louisville, Medical Department, in 1874, died at his home, from Bright's disease, on October 16, aged 66 years. Dr. O'Daniel had served as chief surgeon of the Missouri Pacific Railroad for seventeen years.

Dr. Percy Guy Davis of Deerfield, Mass., a graduate of Baltimore Medical College in 1896, died suddenly at his home on October 20, aged 49 years.

Obituary.

LIEUTENANT-COLONEL EDGAR ALEXANDER MEARNS,

United States Army.

Dr. Edgar Alexander Mearns, Lieutenant-Colonel, United States Army, retired, died at the Walter Reed General Hospital, Washington, D. C., on November 3, aged 59 years. Dr. Mearns was born in Highland Falls, N. Y., and in 1881 was graduated from the College of Physicians and Surgeons, New York. Two years later he was appointed assistant surgeon in the medical corps of the United States Army, and rose steadily in the service until on January 1, 1909, he was retired for physical disability with the rank of lieutenant-colonel. During all this time he devoted himself to the study of natural history, and wrote largely on the subject, his published works numbering, it is said, one hundred and twenty-two. Of the whole collection of birds in the Smithsonian Institution, one-tenth are credited to his efforts, and the Institution is also the richer as the result of his two trips to Africa, the first in 1909-10 as the Smithsonian representative on the Roosevelt trip, and the second a year later with the Childs-Frick expedition. His last work was the report of these two expeditions.

Correspondence.

SAMUEL COOPER'S TEACHING ON PUS.

To the Editor of the Medical Record:

Sir:—Dr. John W. Wainwright found an old book in a garret in Cherry Valley and kindly sent it to me. This volume proves to be "First Lines on the Practice of Surgery," by Samuel Cooper, first edition, London, April 30, 1807. The time corresponds with Napoleon's invasion of Spain, and Cooper was surgeon "To the Forces" (British). In view of a recent editorial article in the Medical Record about "Laudable Pus," possibly this abstract from a work more than a century old may prove of some interest:

"The sympathetic fever attendant on inflammation has been considered an essential step to suppuration; but with little foundation. Is there not a regular secretion of pus from the most indolent ulcers? Is there not the same process on every blistered surface? In such cases is there not oftentimes a total absence of fever?

"That dead animal matter cannot be converted into pus is proved by sloughs of the cellular membrane, tendons, fasciæ, etc., remaining unchanged in abscesses a considerable time and by dead bone lying unaltered in pus for many months. Whatever diminution of these substances may, under such circumstances, happen, occurs only on that side which is next to the living solids and can be satisfactorily accounted for on the principle of absorption.

"Pus always partakes of the nature of the sore which produces it. To the surface secreting it pus is quite unirritating though it may greatly irritate any other. Hence, it is useless to wipe matter so

completely from the surface of granulations as some are wont to do; but it is highly proper to keep the surrounding skin free from it.

"Stimulating antiseptics such as spir, vini camph., olterebinth, etc., may diminish fetid effluvia; but they are apt to create a renewal of sloughing when they extend their action to living parts."

It may not be amiss to say that Cooper treated contused wounds with solutions of alum and of "acetite of lead." Probably every surgical clinic in our city if not in our country is using, to-day, R. Alum ʒss., Plumbi acet. ʒi., Aq. ʒiv. It is termed "alum acetate solution."

DOUGLAS H. STEWART, M.D.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

WOMEN'S WORK AT THE FRONT—DR. ELSIE INGLIS IN SERBIA—ROYAUMONT—VISITED BY PRESIDENT—FRENCH SOLDIERS AT ROYAUMONT—THE LATE T. J. WALKER—SOCIETY OF CHEMICAL INDUSTRY—BRITISH DYES.

LONDON, October 14, 1916.

WOMEN'S work at the front appears to be a great success and owes much to Dr. Elsie Inglis, whose devoted service with the Scottish women's hospital units in Serbia has elicited admiration in all directions. Since the first efforts in this direction the work has grown steadily and the example of the pioneers has been followed by English, Irish, and Welsh women, though the organization still retains the name of Scottish Women's Hospitals and its headquarters are in Edinburgh, and the wounded of our French, Belgian, and Serbian allies have reaped the benefit of services which were at first offered to but declined by the British government. Dr. E. Inglis is now at the head of seventy-five British women, forming the staff of two field hospitals, a large motor transport section—serving with the Serbian army in the Dobrudja. The units are literally women's units, for not only are the medical officers all women, but the transport, the sanitary work, the motor repairs, and all work in connection with the hospitals is done by women. The French and Serbian authorities have often given expression to their gratitude for the splendid achievements of the Scottish Women's Hospitals. One of the places giving most fruitful results is Royaumont, where our ancient abbey has been transformed into a well-equipped institution for the treatment of French wounded. This was begun with one hundred beds, but these have now been increased to four hundred. At a meeting in London lately Miss Cicely Hamilton, who has devoted much time and work for the past two years to this hospital, gave an account of its doings and spoke with enthusiasm of the reputation which British nurses and hospitals have acquired in France and of the abounding gratitude of the French people. Between 3,000 and 4,000 French soldiers have already been treated at the Royaumont Hospital, which was recently visited by President Poincaré, who expressed admiration of all he saw there. An appeal on behalf of the London Committee was made by Miss Mary Lowndes and supported by Lady Emmott.

You will probably remember the name of Dr. Thomas James Walker, a foremost physician in the provinces, local secretary to the Archæological Congress in 1862, and author of the "History of the French Prisoners at Norman Cross" (1913). Last year the honorary freedom of the city of Peterborough was conferred on him on his eightieth birthday. He was an original member of the Northamptonshire Volunteer Corps and held the rank of Lieutenant-Colonel. Of his family of thirteen children, six sons are now serving in the navy or army.

The recent meeting of the Society of Chemical Industry took into consideration the position and prospects of the dye and fine chemical industries, which seem to have suffered from lack of cooperation. From their proceedings it seems that if we are to recapture the color and fine chemical trade we must give more scientific attention to the tar industry and we need a central research laboratory. Protection for British dyes was brought up, but the idea obtained very little support. It was stated that Germany would flood the market with fine chemicals at a loss, if allowed, rather than not hold monopolies. It was said that we are now self-supporting as to the salicyls, and it was hoped we should not let them again become a German monopoly. It was argued that some degree of protection for the next ten years was needed by the manufacturers of organic synthetic drugs, as without it what had been achieved would be lost by Germany's state aided and organized opposition.

Progress of Medical Science.

Boston Medical and Surgical Journal.

October 26, 1916.

1. Anterior Poliomyelitis. A. J. McLaughlin.
2. The Occurrence and Diagnosis of Pericarditis. Edwin A. Locke.
3. A Second Note on the Frequency of Epilepsy in the Offspring of Epileptics. D. A. Thom.
4. Artificial Heliotherapy: The Mercury Vapor-Quartz Light a Valuable Therapeutic Agent. John Bryant.
5. The Treatment of Obesity by a Rational Diet. Edward E. Cornwall.
6. The *Streptococcus Mucosus Capsulatus* as a Cause of Mastoid Disease. Gorham Bacon.
7. A Case of Double Empyema Successfully Operated Upon, with Remarks Upon Localization. F. B. Lund and H. Morrison.
8. A Case of Bloody Tears. M. J. Konikow.

1. Anterior Poliomyelitis.—A. J. McLaughlin, who has made observations with reference to poliomyelitis in Massachusetts during the recent epidemic, agrees with other writers as to the source of infection of this disease and reviews some of its epidemiological peculiarities. He states that most diseases spread in a regular progression along the lines of travel. This applies even to those diseases which are spread by insects, but is not true of poliomyelitis, which frequently skips an intervening city between two badly infected cities. He finds that it frequently attacks less than one person per thousand population. Two explanations of this have been advanced, either that the amount of susceptible material is limited by some immunizing influence or that its transmission is devious and selective, involving possibly an animal reservoir and an insect transmitter. The prevalence of the disease seems to be greater in rural and suburban districts than in cities. The most consistent epidemiological character of poliomyelitis is its age incidence. The writer has made an effort to determine whether the age limit of those attacked was the same in rural and urban outbreaks. The prevalence of the disease in 15 towns, ranging in population from 427 to 2,213, was compared with that in the worst stricken of the smaller cities, North Adams. The total population of the rural groups was 23,361; that of North Adams 22,939. The attack rate was nearly the same in the two. In the rural group there were 37 under five years of age, 26 between the ages of five and ten, and seven over ten years; in the North Adams group there were 76 under five years of age, 24 between five and ten years of age,

and none over ten. This is suggestive that the age limit of susceptible age groups may be higher in rural and suburban life. The writer thinks it not improbable that an active immunizing influence is going on constantly, constituting an endemic prevalence of this disease, with relatively few paralyzed cases. This hypothesis would best explain the age incidence of the disease, for with a widespread infection opportunity is afforded for obtaining immunity in the first years of life. Theoretically, such a process of immunization would be most active where opportunities for contact were greater, that is, in the city. If this reasoning is sound we should not only have a lesser number of immune persons in the country but the susceptible groups would have a higher age limit.

2. **The Occurrence and Diagnosis of Pericarditis.**—Edwin A. Locke comments on the relative infrequency with which pericarditis is seen clinically in comparison with its relative frequency at the autopsy table. He has made a careful study of the autopsy reports of the Boston City Hospital for the past nineteen years together with the clinical records of the same cases. The total number of post-mortem sections was 3683. In this series acute lesions of the pericardium were described in 150, and chronic lesions in 209 instances. Exclusive of these 359 cases of true pericarditis, 88 showed milk patches in the pericardium. These figures show that acute pericarditis was found in 4 per cent. of all autopsies. In this series of autopsies acute endocarditis was described in 5 per cent. and chronic endocarditis in 12.6 per cent. In only 27 instances among the 150 cases of acute pericarditis was there any clear evidence in the clinical notes of the presence of disease of the pericardium. A detailed study of the various types of pericarditis found reveals an even greater deficiency in the clinical work. The most glaring errors are in the cases of pericarditis with effusion of various forms. The writer believes that in at least 50 per cent. of these cases it should be possible to diagnose this condition with reasonable certainty. Rheumatism is the commonest cause, and in adults pneumonia and pleurisy probably comes next. A less common cause is tuberculosis of the thoracic organs or acute miliary tuberculosis. The clinical picture is difficult to give. In not a few instances the onset is more or less well marked. The patient becomes restless, breathes with a shallow, rapid respiration, looks distressed and anxious, the face has a dusky pallor, and the patient complains of pain or oppression in the region of the precordia. Later symptoms depend largely on the degree of cardiac embarrassment and pressure from the distended pericardial sac. In the early stage the first and most important sign is the friction fremitus. As a rule this is double, though fairly commonly it occurs as a single sound, or rarely triple. The pericardial sounds never begin or end with a shock and are characterized by the same intensity throughout. The commonest areas where they are heard are at the base and over the middle portion of the heart. It seems not improbable that in a not insignificant percentage of the cases the rub is heard over a relatively wide area of the thorax and in the lower left back also. The physical signs of adherent pericardium are described together with the characteristics of adherent pericardium in roentgenograms, and the opinion is expressed that, considering the relative frequency of pericarditis and its favorable course with spontaneous recovery in many instances, paracentesis is rarely necessary.

3. **A Second Note on the Frequency of Epilepsy in the Offspring of Epileptics.**—D. A. Thom has made an intensive study of cases already reviewed in a previous article to determine to what extent epilepsy is transmitted directly from parent to offspring. Thirty-three matings are considered which resulted in 133 offspring. Of these 86 are living and 47 dead. Of the total 133 offspring there is a history of convulsions in 10, five having died in infancy, during seizures, two becoming arrested cases, and three confirmed epileptics. The group of living offspring contains 46 cases still under 20 years of age. The writer thinks it is not probable that 50 per cent. of these will develop epilepsy, while in the cases over 20 years of age heredity will play a much less important part. The results of his earlier work have been to a large degree substantiated and his conclusion that epilepsy is less often transmitted directly from parent to offspring than we have heretofore been led to believe seems to be justified.

6. **The Streptococcus Mucosus Capsulatus as a Cause of Mastoid Disease.**—Gorham Bacon states that according to his experience the *Streptococcus mucosus capsulatus* is the most destructive germ with which the otologist had to contend, and the question of an operation when the mastoid cells are involved is a most important one. He cites a number of cases which serve to emphasize the following points: 1. The patient may have very severe pain, or the pain may be slight, and the temperature is seldom much above normal. 2. Tenderness on pressure over the mastoid process may be well marked, or there may be none, especially where the outer cortex is thick. 3. The discharge in some cases is very profuse, while in others it is slight, and there may or may not be sagging of the posterior and upper canal wall. 4. The *x*-ray is a most valuable aid, as the cells on the affected side will be cloudy, and in some instances it is possible to detect an epidural or perisinous abscess. 5. We should err on the safe side and operate when in doubt, for we often find a great destruction of bone, even in cases that present few symptoms. It is only in a few cases, which yield readily to treatment, that an operation can be avoided.

2. **Sources of Error in Diagnosis.**—Edward C. Hill discusses the principal causes of diagnostic error under some dozen different headings, such as mistaking symptoms for diseases, effects for causes, overlooking the focus of infection, disregarding diet and habits, neglecting the mechanical factor, slighting the reflexes, ignoring the psychic factor, diagnosis by proxy, diagnosis by predilection, the pathognomonic delusion, the using of names without sense, and sheer ignorance. He has differentiated some one hundred and seventy-five causes of headache, scarcely any two of which should be treated just alike. A cough may arise all the way from wax in the ear to an incompetent heart, as well as from any affection of the respiratory tract. Albuminuria accompanies a hundred different conditions besides organic affections of the kidneys. Iron and arsenic may be of great service in treating anemia, but the cure must be sought further back than in the blood. Pleurisy is practically always a complication of pneumonia, tuberculosis, or some other general infection. Most cases of so-called ptomaine poisoning are either acute indigestion from excess of food or an incom-

patible combination of foods, or else some more or less obscure surgical condition, such as perforating duodenal ulcer or mesenteric thrombosis. In discussing the mistakes made by slighting the reflexes, the writer considers the reflexes in angina pectoris, and points out that he has met cases in which pain was referred to the left arm, and a case of pneumonia of the right lower lobe, with marked diaphragmatic pleurisy, involving the phrenic nerve, which was apparently responsible for pain in the right side of the neck as the chief subjective symptom. Mackenzie calls attention to cases of gallstone disease that have been treated for years for neuritis. A considerable number of physicians have mistaken a basal pneumonia of the right side for acute appendicitis. Of all origins of referred and reflex sensory symptoms probably the prostate gland is the most prolific source of diagnostic error. No more frequent error is made than to base a diagnosis upon a single symptom or sign. If a patient shows loss of knee jerks he is liable to be set down at once as syphilitic, whereas there are at least thirty conditions in which knee jerks are absent and of these hysteria and multiple neuritis are probably the most important. The practical utility of a study of the cytology of the stomach washings in demonstrating the presence of cancer cells is emphasized, and also that slight degrees of excess of deficiency of the ductless glands are especially liable to escape detection in the present state of general ignorance of this province, although such changes may easily account for otherwise obscure symptoms. It may be possible that the control of cell anarchy called cancer lies in the study of these glands.

5. **Treatment of Bladder Tumors.**—J. T. Geraghty relates his experience with 180 cases of bladder tumors from which he concludes that benign and malignant papillomata should be treated by fulguration; excision or resection should not be practised except in cases in which intravesical treatment is impossible or very difficult. Radium he has found a great aid in the treatment, particularly of the malignant papillomata, and the best results were obtained when the radium was placed directly against the tumor. When the tumor is a papillary carcinoma, resection should be practised by a technique which will reduce to a minimum the dangers of implantation or recurrence. Radium as yet has not given results in this type of tumor sufficiently encouraging to warrant its employment in preference to resection in cases which are considered operable. Following resection, cystoscopy should be performed at an early date, and at frequent intervals, especially for the first year, and if recurrences are noted, they can occasionally be successfully treated by a combination of fulguration and radium. Unfortunately a large percentage of cases are first seen when the disease is so extensive that nothing more than palliative measures can be adopted. In 69 of the 180 cases in this series the tumors were so extensive and so hopelessly inoperable that nothing more than palliative measures were adopted.

6. **Tumors of the Bladder.**—Leo Buerger writes that from a study of 113 tumors of the bladder, among which were 55 papillomata, 45 papillary carcinomata, five squamous carcinomata, two metastatic carcinomata, and six sarcomata, he concludes that a differential diagnosis between papillomata and carcinomata can be made in almost all cases on a pathological basi. Certain morphological criteria were accepted as indicating the existence or the acquisition of malignant traits in any given tumor. These criteria were found to be present in parts of the tumor that were accessible, so far as they could be reached by cystoscopic instruments, and so far as adequate portions could be removed for histological examination. The changes indicative of malignancy occur, not as heretofore assumed, in the "depth" where they may escape our diagnostic methods, but first, in the epithelium, not far from the surface, either with or without areas of infiltration. A test of the morphological criteria proved conclusively that they were trustworthy and, if adopted, led to correct diagnosis. Many of the other loosely accepted notions regarding the malignancy of papilloma *per se* were found to be fallacious. Only in one tumor out of 113 was a papilloma found to infiltrate and still retain "normal" cellular characteristics. A trustworthy pathological diagnosis and the possibility of differentiating between carcinoma and papilloma depend upon our opportunities of obtaining material and upon our ability to recognize the criteria laid down as indicative of malignancy; that the latter are present this series of tumors has definitely shown.

11. **The Clinical Thermometer as a Carrier of Infection.**—L. Martocci-Pisculli calls attention to the danger of conveying infection from one patient to another by means of the clinical thermometer. Many physicians content themselves with rinsing their thermometers in cold water and then using them on one patient after another. A number of thermometers were taken from various physicians in order to determine whether germs were actually carried in this way and whether they could be recovered and grown in culture media. Several dozen thermometers were examined by competent bacteriologists in the research laboratory of the New York City Department of Health. It was found that all thermometers taken from patients carry live pathogenic germs and are therefore disease carriers. Washing them in water and wiping them dry in no way destroys the germs or even reduces the danger of carrying infection. Cool water hardens and so fixes the mucus with the containing bacteria on the thermometers. It is absolutely imperative to disinfect the thermometer after using it on a patient. Physicians must either devise some method of disinfecting the thermometer while carrying it in its case, or spend a few minutes in each patient's house to disinfect it.

3. **The Ultimate Results in the Treatment by Artificial Pneumothorax.**—A. G. Shortle says that during the

past four years there have been published in America numerous reports on the treatment of lung tuberculosis by artificial pneumothorax, and these have proved beyond doubt the value of this procedure so far as the early symptomatic results are concerned, provided properly selected patients are operated on. After briefly summarizing the little that is to be found in the literature, he deals with only 104 cases, twenty-five of which are to be eliminated as they proved inoperable, and were of interest only in showing that almost one case out of four had such extensive adhesion that operation was impossible. This left seventy-nine cases that allowed of sufficient collapse to produce therapeutic results. Of the seventy-nine patients, thirty-five are dead, two were apparently made worse, eighteen were improved, and twenty-one were discharged and treatment stopped [leaving those cases unaccounted for]. Out of seventy-nine patients receiving lung collapse, nineteen are today working and in good shape physically; a number of these are symptom free. Three others discharged as improved are working but show marked involvement of the lung. A good proof of the class of patients operated on is afforded by the fact that of the twenty-five patients who proved to be inoperable on account of adhesions, sixteen are dead, and seven are living, but in bad shape physically. Of the inoperable patients only two, or 8 per cent., are working, and only one, or 4 per cent., is improved; while of the patients operated on, twenty-two, or about 28 per cent., are working, and nineteen, or 25 per cent., are in good shape physically. Their results appear to be much better than those of other operators. He ascribes this only to the following factors: (1) Most of their patients have been treated in their sanatorium, where the complete rest so essential to good results can be enforced. He often felt with Saugman that the procedure should not be undertaken outside an institution. (2) Their patients have been largely of the more intelligent middle class, with sufficient funds to afford proper living conditions and with sufficient brains to lend intelligent cooperation. (3) They were all treated in a very favorable year-round climate. (4) This he considered important: They received small insufflation of gas, never exceeding 500 c.c., and as a rule 250 to 350 c.c. The habit of introducing 800 to 1000 c.c. at one operation is always sufficient explanation to me why a given operator has not had success with artificial pneumothorax.

5. **Death Rate in Acute Infections.**—Edwin E. Graham. (See MEDICAL RECORD, June 24, page 1160.)

6. **Fractional Determination of Gastric Secretions.**—Ernest C. Fishbaugh reviews this subject, aiming to avoid a consideration of the diagnostic, prognostic, and therapeutic possibilities suggested by the various curves presented, and simply points out the value of interval examination of gastric secretions, and emphasizes the valuelessness of the ordinary one hour examination. The association of the various types of curves with symptomatology and therapeutic management have been purposely reserved until more extensive data are at hand. It seems from an analysis of the fractional study of gastric secretions in this group of cases, that the following conclusions are justifiable: (1) One hour stomach examinations afford insufficient and often misleading information concerning the acidity and enzyme secretion. It gives no evidence of the secretory curve. (2) The fractional method of stomach examination follows the entire cycle of digestion, and supplies reliable information concerning the type of secretory curve, the degree of acidity, the ferment content, and an accurate estimation of the emptying time. (3) By fraction study, stomach secretions fall into three groups: (a) stomach secretions whose curves fall toward the end of gastric digestion; (b) stomach secretions whose curves rise to the end of gastric digestion, and (c) stomach secretions delayed or absent.

7. **Radical Operation for the Cure of Cancer of the Second Half of the Large Intestine, Not Including the Rectum.**—William J. Mayo. (See MEDICAL RECORD, July 8, 1916, page 82.)

8. **The Corpus Luteum.**—Emil Novak. (See MEDICAL RECORD, June 17, 1916, page 1113.)

9. **Lepra Mutilans.**—Melvin S. Rosenthal reports a case presenting the syndrome of the clawlike contraction of the fingers, followed by painless and gradual loss of the digits, complete anesthesia, mutilation and thickening of the face, ulceration around the mouth and nose, and leucodermic spots on the hands and feet; this should identify the case as one of leprosy without the refinement of differential diagnosis. The patient was a well nourished black negro, apparently about 40 years of age, and had been able to follow his occupation as a bootblack continuously until the diagnosis was made. By means of leather bands into which his hands were fitted he was able to hold his brushes and shine shoes. His patrons were largely medical students, and it was through the curiosity of one of these that he was induced to visit the hospital, where the diagnosis was made. The horror with which the public views leprosy makes the disposition of these cases a difficult problem. While direct evidence is lacking as to the communicability of the disease in this climate, it is assuredly hazardous and undesirable to allow absolute freedom to a poverty-stricken individual lacking all the facilities for ordinary cleanliness, living in filth and squalor, and incapacitated by his deformity from caring for himself. The man roams at freedom, using the street cars and telephones, handling money as he sees fit, and living in the same sordid, unhealthy surroundings in which he was originally found. This case well illustrates the urgent need of a national leprosarium where these unfortunates can find a permanent refuge and the community be spared the presence of an unsightly, mutilated and incurable human being awaiting the final call.

16. **The Comparative Resistance of Bacteria and Human Tissues to Certain Germicidal Substances.**—Robert A. Lambert says that it is recognized that an ideal germicide for use on infected tissues of the body is one that will kill the pathogenic microorganism present without at the same time injuring the tissues. From experiments made it has been concluded that the method of tissue cultures affords a simple, direct, and easily controlled method of determining, under conditions analogous to those in the body, the relative resistance of tissues and bacteria to various chemical agents, including the common germicides. Of the germicides tested, iodine is the only one which will kill staphylococci in strengths which do not seriously injure tissue cells. It is possible, however, that on account of the fibrin-dissolving property of iodine, causing conceivably inhibition of wound healing, some other substance may be found approaching more closely the ideal tissue disinfectant.

2. **The Relation of the Enterococcus to "Trench Fever" and Allied Conditions.**—Thomas Houston and John M. McCloy present the results of investigations carried out in the St. John's Ambulance Brigade Hospital which have revealed the presence of the enterococcus in numerous diseased conditions. In the course of routine work evidence has accumulated which indicates that this coccus is an infective agent in many of the cases admitted to the medical and surgical wards. The cases in which infection with the enterococcus was found do not conform to a disease of special type, having characteristic clinical features. Most of the cases, however, have certain symptoms in common, notably sudden onset with fever, headache, often orbital, loss of appetite, furred tongue, and pains in the back and lower limbs, especially the shins. For purposes of description these cases are classified in the following groups: (1) Septicemic, (2) "trench fever," and (3) myalgic. The latter group contains the largest number of cases of enterococcal infection which have been investigated. The bacteriological methods employed in isolating the organism from various sources are described. They have found the blood culture a very valuable method of diagnosis when positive results are obtained, but disappointing in that in many cases of apparent septicemia no organism is found. In the enteric group of diseases the infecting bacillus is rarely found in the blood after the first week of illness. A bacteriological examination of the wounds in 110 instances revealed the presence of the enterococcus in 41 per cent. of the cases. An examination was made of 543 urines, which showed the presence of the enterococcus in 18 per cent. of the cases. It seems that when this organism is found in the urine it is frequently an infecting agent. It may be, however, that its presence in the urine is not always of pathological significance. In the examination of twenty-eight sputa from cases of several different diseases, the organism was found in eight, and in these cases there was other evidence of infection with this coccus. In a number of cases opsonic index determinations were made, and evidence of infection with the enterococcus found. In many of these cases the vaccine treatment appeared to be of decided value.

3. **The Diagnosis of Tuberculosis by Tuberculin.—A Study in Technique.**—H. A. Ellis reviews the Calmette, Moro, and von Pirquet tests, and points out the objections to their general use. The failure of these methods to give entire satisfaction has led him to the adoption of a method which he describes and calls the papillary cutaneous method and the multi-papillary cutaneous method. This is done to distinguish it from von Pirquet's, or the mucous cutaneous method. The test is based on the fact that the papillary layer of the skin is the one influenced by tuberculin, and that it reacts to graduated doses, in definite proportions to the doses employed, with mathematical accuracy consistent with the character of the case. Usually six scarifications are made to which are applied graduated doses of tuberculin; there is also a control scarification. It has been found that the results are definitely proportional to the dose and the final reaction. There is a distinct connection between the multi-papillary cutaneous reaction and the class in which the case is, and this relation is sufficiently definite to be of great aid in diagnosis and prognosis. When the reactions do not agree, further investigation usually demonstrates the cause, for instance the lowering of the reaction by a previous course of tuberculin treatment. The results also indicate that the highest multi-papillary cutaneous reaction occurs comparatively early in the case; a greater subsequent extension of the disease gives a lower reaction. The writer believes he has sufficient evidence to justify the statement that the multi-papillary cutaneous test properly carried out materially facilitates the early recognition of the condition of active tuberculosis, is a material aid toward a general prognosis and a valuable indication in tuberculin treatment.

4. **A Note on the Use of Celluloid in Plastic Surgery.**—Charles Higgins states that during the past six months he has had the opportunity of doing from 80 to 100 plastic operations on the face, the greater part of them being for scarred or lacerated eyelids and shrunken sockets, though there were a number of deeply scarred faces and noses smashed flat. He found that paraffin when used to fill up a scar generally found a way to get out of position, and was anything but satisfactory. It then occurred to him to try celluloid. He has since used celluloid for replacing bone, and solutions for filling cavities and raising deep cicatrices. He uses two solutions, one celluloid dissolved in acetone, the other a secret preparation, made originally for trade purposes, its use being to make bad corks watertight and airtight. In all cases he has covered the celluloid over with skin taken from the remains of the part to be reconstructed, or by a flap removed from the immediate vicinity and attached by a pedicle. The only precaution he has found necessary to adopt is to take care that the celluloid plate, which is rather sharp, should not coincide with the line of suture after the wound is closed. This is easily obviated by undercutting the outer edges of the wound to be filled in, and pushing the edges of the plate beneath the skin so raised that its margin is external to the line of suture. In operations for the removal of cicatrices the fluid preparation is more satisfactory than the plates. This is introduced by making a tunnel under the scar and then injecting the fluid by means of a syringe until the scar rises a little above the level of the surrounding tissue. The writer entertains the hope that celluloid fracture plates may take the place of the steel plates now in use.

5. **A Case of Chorion-Epithelioma.**—H. Neville Taylor reports the case of a woman who had undergone a curettage for irregular hemorrhage, and a month afterward began to suffer from metrorrhagia and vomiting. It was thought that probably she had had an early abortion and that there might still be something retained. The vomiting and hemorrhage subsided under medical treatment. About three weeks later the bleeding recurred, and the patient was anemic with a very "malignant" look. A specimen was removed for examination. This was followed by further bleeding and the death of the patient from syncope. The specimen removed belonged to the second variety of chorion-epithelioma, as described by Galabin. In this case there had been no amenorrhea since the last pregnancy, two and one-half years previous, and no other suggestion of pregnancy. If deciduoma malignum is always the result of conception, and there was no conception in this case, then it is necessary to go back to the last pregnancy, over two years previous, to account for the chorion-epithelioma. Other cases have been reported which give ground for believing that in exceptional instances there is the possibility of such a latent period.

1. **Remarks on Emergency Amputations in Military Surgery.**—J. Lynn Thomas states that the following are the essential points in carrying out the circular amputation with lateral incisions: (1) The level at which the section of the bone is to be made must first be determined. (2) The proximal ends of the lateral incisions begin at this determined point, and are carried down to the bone and continued toward, or into, the damaged tissues. (3) A clean knife must be used for each lateral incision if available; if not, the knife should be thoroughly wiped and sterilized with flame. (4) The soft tissues are then divided by one clean sweep down to the bone after the manner of the old circular method. (5) The two flaps thus produced by the combination of the circular and the lateral incisions are retracted and the bone is sawn through at the level previously determined. (6) The vessels are ligatured with silkworm gut or catgut, not thread or silk, for fear of sepsis in the wound. (7) The flaps are then forcibly pulled down, forming a funnel-shaped cavity, in which the muscles are not in apposition. (8) This cavity is firmly packed with sufficient gauze wrung out of Wright's hypertonic salt solution or Dakin's fluid, so as just to allow the flaps to meet firmly over the packings. The flaps are secured in position by three strips of self-adhesive strapping and the ends of the gauze are allowed to project at each corner through the lateral incisions so as to insure efficient drainage. The ordinary rubber drainage tubes, Thomas says, must not be used at all.

2. **The Intraspinal Treatment of Syphilis of the Central Nervous System.**—A. Rocke Robertson reports eight cases, two of which showed early, and one a slight, involvement of the central nervous system within a year of the primary infection. Each had received during the secondary period a single injection of salvarsan, followed by maximal doses of mercury by mouth without, however, preventing the onset and progressive involvement of the central nervous system. It may be presumed, therefore, that this treatment was inadequate. A single combined treatment by intravenous salvarsan and intraspinal salvarsanized serum in one case sufficed to clear up the leucoplakia on the tongue and convert the pathological spinal fluid into a normal fluid. The other six cases were of long duration, and showed various manifestations of the disease. The consideration of these eight cases from both a clinical and laboratory standpoint shows that we have a powerful form of therapy in the combined intravenous and intraspinal treatment.

4. **Further Experiments on Ascaris Infection.**—F. H. Stewart records some experiments made since the paper published in the *British Medical Journal* of July 1 was written, and offers the following conclusions: If ripe eggs of *Ascaris lumbricoides* are swallowed by rats or mice they hatch. The larvæ enter the bodies of the rodents either by boring into venules of the portal system or by ascending the bile duct. They are found in the dilated blood capillaries of the liver, between the second and fifth days. The larva is in diameter three times the diameter of a red blood corpuscle of the mouse. It cannot, therefore, pass through a normal capillary. The liver cells in the neighborhood of the larvæ undergo rapid degeneration. The larvæ are thus enabled to work their way into the hepatic venules and pass by the hepatic vein and vena cava to the heart and by the pulmonary artery to the lungs. In the lungs they are filtered off at the entrance to the capillary field. Embolism of the arterioles takes place, and the larvæ pass with the effused blood into the air vesicles. They are found in the air vesicles on the sixth day, in the bronchi on the seventh day, and in the trachea and mouth on the eighth day after infection. It is probable that they emigrate in the saliva of the rodent on to food substances, such as bread. It has been shown that they can live for twenty-four hours on damp bread. The experiments which have been conducted so far tend to prove that the larvæ from the lungs of rodents can infect the pig, and it is probable that in nature infection of man and the pig takes place by food contaminated by rats or mice.

7. **A Universal Leg Frame, Splint, and Cradle Combined.**—Martin J. Chevers described this splint which consists of a galvanized metal frame, thirty-two inches long, seven inches deep, and nine inches wide; along the top on each side is fixed a row of brass studs, which serve to secure a series of ten straps. These straps, each three inches wide, are eyeletted, so as to be adjustable to half an inch; they are made of waterproof material, and may be sterilized by boiling. The advantages he claims for the splint are: (1) It is adaptable to any size, shape, or length of limb or amputation stump, and removal of one or more straps when being used on either the anterior or posterior aspect of the limb allows of easy access to a wound wherever it is placed without disturbing the limb. (2) By removing a strap, heel pressure can be relieved. (3) Elevation of the limb can be attained by steady graduated support to the whole under-surface. (4) It can be used as a double inclined plane by regulating the straps. (5) One or more straps can be used over instead of under the limb or amputation stump in order to steady it. (6) If alternate straps are lowered nearly to the bed, but so that the leg still swings, and the others buttoned tense across the top of the splint, the latter act as a bed cradle or as a rest for lotion trays or irrigation solution. (7) If any portion of the foot should project above the splint, an adjustable and detachable guard (∩ shaped) can be used; its legs fix firmly in holes placed at intervals in the upper parallel bars of the splint to remove the weight of the bed clothes at any required spot; this guard has a notch at the top, so that if the leg has been placed in another splint it can be suspended from the notch. (8) The waterproof straps are specially useful for keeping an ice-bag or dressings in place when the constriction of bandages is not advisable, or when excessively moist dressings are necessary, or where continuous irrigation is required (the receptacle being placed within the splint, underneath the suspended leg.) (9) The splint, when the limb is suspended in it, is almost immovable by the patient on any ordinary mattress and covering. (10) The foot may be kept at right angles to the leg or valgus prevented by wrapping two or three turns of a bandage round the foot and making the ends fast at each side to the perpendicular or parallel bars. (11) For fractured patella the splint acts better than a Thomas knee splint on account of the steadiness of the side bars, over or round which the bandages are passed, and across the front of the leg, keeping a firmer pressure on the pads placed above the upper fragment and below the lower fragment. (12) In cases of severe infection, where flush amputation has been necessary, skin traction in after-treatment is facilitated. (13) The waterproof straps can be made use of for a Thomas knee splint. (14) The disturbance caused by putting on and taking off bandages, the heating and constriction of the limb which may be the result of bandaging can all be entirely done away with, the straps being used instead.

Le Bulletin Médical.

October 7, 1916.

Troubles of Growth in Early Childhood.—Lesage refers to the period between the first and fifth years. There may be an arrest of growth in the first childhood, producing dwarfism in comparison with the stature of other children of the same age. This, a transitory condition, has nothing in common with nanism or true dwarfism, although there is often a close parallelism between the two. In some of the cases the stunted growth is due to defect in one of the glands of internal secretion, usually the thyroid or hypophysis. In the simpler forms the giving of one extract alone is sufficient to restore the ability to grow; but cases occur in which one has to experiment with various glands and combinations of the same. In certain cases they are all given in concert and good results follow. In an entire series of cases, however, the total failure to respond to opotherapy makes us think the other causative factors are concerned. The author accuses here a certain "digestive debility" noted even in the first year of life, and often inherited. The children and the stock from which they spring are arthritic. The child never has much appetite and seems to live on nothing. The trouble usually begins with attempts to wean. Nothing can overcome the anorexia, save when at rare intervals something pleases its palate. It has a marked intolerance toward milk, and often toward eggs. From lack of eating the tongue is always coated. Hence the parents are led to give purgatives. When these are not indicated, the stomach is atonic and secretes but little; it is often distended with gas. The production of bile is feeble. The bowels are never regular and constipation is the rule. There is much more fecal matter than could be expected under the circumstances, and its odor is very fetid. On physical exploration one is impressed by the small size of the liver under fasting conditions. If now the child partake of food of poor quality the torpid or quiescent state of the liver is at once succeeded by a congestion which is accompanied by great pain. Such children are sometimes operated on for appendicitis, but the surgeon finds only a distended cecum and colon. The appendix is removed but no benefit results. The torpid and shrunken liver should warn against abuse of anesthetics. Insomnia is common. As for the mental state, it goes to extremes—the child may be excitable or apathetic. Crises of vomiting occur, not due to acetone. The condition becomes fixed and chronic until it is termed a digestive cachexia. Its appearance is signaled by notable arrest of growth. In such cases the author believes that we have to do with a pure deficiency disease—a liver too small and weak for the economy to thrive. The indication is for hepatic extract, given either as a press juice or in powdered form. The dose should be very small—two or 3 grams daily of the latter, and in combination at times with thyroid extract, calomel, or ipecac.

La Presse Médicale.

September 28, 1916.

Hereditary Syphilis in the Third Generation.—Gautier described the following at a very recent meeting of the Académie de Médicine. The great grandfather died young of syphilitic paraplegia. The grandfather never contracted syphilis, and this is true of the father. Of three children born to the latter, one was backward, almost an idiot. The others presented no stigmata of congenital syphilis, but both had to be operated for adenoids, and one had skeletal and dental peculiarities. The Wassermann was positive in the father and all the children, and negative in the mother. The author regards the various ailments of the three children as all due to ancestral syphilis. These comprised cerebral dystrophy (idiocy), dental dystrophies (gap between central incisors), high palate, scoliosis, adenoid vegetations, strabismus, enterocolitis.

Icterus from Picric Acid Poisoning.—Brulé, Javillier and Baeckeroot, out of a large material of jaundice, discovered that ten cases were due to ingestion of picric acid, and hence were supposed examples of "false jaundice." The diagnosis should be simple, because there should be no bile pigments in the urine. Experiment, however, appears to show that picric acid causes a lesion of the liver, and therewith sets up true jaundice. The problem is one of chemistry alone, and the conclusions are as follows: icterus which follows ingestion of picric acid is an example of true icterus which cannot in any respect be distinguished from other forms of the latter. The chemical diagnosis is alone sufficient. Should the ingestion have been considerable and recent, picric acid should be present in the urine and recoverable therefrom, otherwise one should seek the presence of picramic acid, which may be present in traces long after the entrance of the drug into the body. If bile coloring matters alone are present, the reactions will be different. The presence of these substances never excludes that of picramic acid; but when, as is usually the case, the icterus is of the mild type, not biliary coloring matter but urobilin should be present.

Cure of Tetanus by Serum Despite Violent Reactions.—Nobécourt and Peyre related this case to the Medico-Chirurgical Reunion of the Fifth Army. A boy of 8 had received a slight wound on the thumb, already cicatrized. He was first seen on the fourth day of a severe tetanus. No serum was injected until seven days later, when 280 cm. of an American antitoxin was injected into the veins, with 40 cm. under the skin and 20 cm. into the cord. For the first six days no improvement was noted. On the sixth day of treatment an urticaria appeared, with fever, tachycardia and meningism. On the ninth day a second intravenous injection of 20 cm. was practised. A violent anaphylaxis at once developed. At the end of three-quarters of an hour there appeared a crisis of contractures, respiratory pauses, cyanosis, pallor, small pulse, etc. This state lasted half an hour. Despite these untoward phenomena, more serum was thrown into the veins. All this while the tetanus was improving rapidly, and at the end of three weeks the child was discharged cured.

La Presse Médicale.

October 5, 1916.

Colloidal Gold in Typhoid Fever.—Salomon first refers to the introduction in 1902 of colloidal silver by Netter, who studied especially its value in infectious diseases. It was noted later that typhoid patients did not very well tolerate the intravenous injection of this substance. In 1914 Letulle and Mage began to use colloidal gold in this manner for the same infection, and during the war it has been tried out on the troops, and its value has been pronounced incontestable. But it has never come into extended use because of its burdensome reactions, which can neither be foreseen nor prevented. Half an hour after an injection the patient experiences a chill and buries himself in the bed clothing; his condition closely resembles an ague, his extremities shake violently with extremely troublesome shocks. There may be vomiting or relaxation of the sphincters. The access lasts an hour or more, until the patient is dyspneic and cyanotic, with rapid, small thready pulse. The physician who is unprepared for such a sequence is in a painful state of mind. The condition slowly passes off, aided by hot drinks and heart stimulants such as adrenalin and camphor. Cya-

nosis may persist for several hours. The chill period is succeeded by one of heat and sweating, the temperature rising to 40° C., or in persons already in a grave, toxic, infectious condition to 42° C.; but after eight to twelve hours it drops to normal and subnormal. During defervescence perspiration is profuse. In certain fortunate cases the temperature does not again rise, but as a rule it soon regains its former level or higher, and further injections must be used. The polyuria which follows defervescence is often extreme. We see after each new injection the same temperature cycle, but the course of the disease does not seem modified; the patient gets well or dies, as under other conditions, but with a better chance for survival. The cardiac crises which require active treatment form the great disadvantage and the injections seem to favor intestinal hemorrhage. Doubtless they have caused death from collapse. The individual reaction shows great variation. A point in favor of the injections is that they become less intense with repetition. The author then gave the subcutaneous method a thorough try out, and found it harmless but inefficacious. He then turned to the intramuscular route and found this method a compromise—decidedly efficacious and free from grave dangers. Much depends on a good technique, which is fully described. Injections should be painless and cause no inflammatory reaction. They should be followed by an abortive chill and slight rise of temperature, succeeded by a fall, during which the patient feels better. The fever returns and the injections may be repeated several times. The intramuscular injections may well be used as a synergist to cool baths and permanent refrigeration of the abdomen—until the value of a specific (vaccination) therapy has been proved beyond doubt.

Reflex Manifestations Following Disarticulations of the Fingers.—Porot refers to motor, vasomotor, and trophic manifestations caused by traumatism of the peripheral nerves. These, in many ways, resemble those due to hysterical and organic disease. Under the term motor he includes the special attitudes assumed by the extremities (overlapping or rigid fingers), the pareses, with modifications of tonicity, and the so-called paratonias. Under trophic manifestations belong muscular atrophies, thinning of the integument and hypertrichoses. Vasomotor manifestations include cold hands, cyanosis, hyperidrosis. In all of these stigmata there is no sign of organic disease, and the neuromuscular reactions are all normal. A study of these phenomena which may be present under a variety of traumatic conditions shows that they are especially common after disarticulations and amputations of the fingers. The wound itself may be trivial. After disarticulation or amputation there is more or less scar formation, but it is impossible to determine the rationale of the manifestations which are seen to follow. To cite an illustrative case, a soldier was wounded in the left index finger by a piece of shrapnel. A few days later disarticulation was performed and the wound healed well. A flaccid paralysis of the arm supervened with segmental anesthesia (suggesting hysteria). Upon examination a reflex hypotonia could readily be demonstrated. There was marked reflex activity; if the injured finger of the paralyzed arm was elevated, an inexhaustible clonus resulted. Idiomuscular contractions were more marked in the affected limb, as was faradic excitability. There developed slight muscular atrophy in the forearm, while the skin was dry, scaly, and odoriferous. The author admits that it is difficult to exclude a hysterical component. Other cases cited do not suggest the latter. Mental tests show a normal psychical coefficient. One patient had developed tetanus from his wound, which complication must be reckoned with as a possible factor in the contractures which followed.

El Siglo Médico.

September 30, 1916.

A Medical Martyr to Infantile Paralysis.—In the medical news column is found an article taken apparently from a lay periodical, which regards the contraction by a physician of this disease as something sensational. In the Spring of 1913, Dr. Mulero Grijalbo, while treating a patient with poliomyelitis, contracted the malady and the resulting paralysis of his extremities has prevented him from following his profession. Technically he was the victim of a professional accident. There is no relief provided in law for such cases and the victim, deprived of his income, was forced to live in a small mining settlement. For twelve years (he is now 35) he had worked with ceaseless enthusiasm and zeal during epidemics of measles, scarlet fever, diphtheria and typhus, only to contract poliomyelitis from a sporadic case. Three children are mentioned as sharing his fate. With a view of making provision for such unfortunate victims the lay journal suggests legislation for the erection of a building for the maimed and crippled in the Department of Viscaya which would provide automatically for a case like that of Dr. Grijalbo. In addition to the Government benevolent societies, private philanthropy and the College of Physicians of Spain should be active in such a movement. A memorial should be presented at once to the law-making body. At present a wounded bull seems to be of more importance to the community than the afflicted physician.

Cocainomaniacs. — Sanchez-Herrero asks, "Why are there seekers for an artificial paradise?" Because degenerates are increasing in numbers, and such men are quite indifferent to their own health and to the perpetuation of the species. What does cocaine do? It prevents the transmission of impressions by paralyzing both centripetal and centrifugal waves for the time being. The addict has a sort of honeymoon period at the beginning of his addiction, or rather before he has become a true addict. As far as cocaine is taken to relieve suffering, the victim of nasal troubles is the most exposed to the cocaine peril. The world of cocainomaniacs is made up of what Gorki terms *submen*, who are denatured, dehumanized; all drug addicts, including alcoholics, tend to flock together. The drug evil has been caricatured as a spider's web with a woman's head in the center. About the web we find degenerates, the unoccupied, neuropathics, weak wills, prostitutes and their *souteneurs*. The drug evil degrades woman; the prostitute takes it to forget or to feel a spark of energy. A special class of addicts is found among writers. No amount of education or wealth can avert this peril. All who fall are alike in becoming antisocial, and those originally antisocial are naturally the easiest victims.

Hereditary Syphilis in the Second Generation.—At a session of the Zurich Medical Society an infant of 8½ months was shown. It was born healthy like the elder children, but in the sixth month hydrocephalus was in evidence, and a month later strabismus. Positive Wassermann in blood and cerebrospinal fluid. No spirochetes. The *x*-ray showed pronounced broadening of the epiphyseal line in the radius and ulna. After five intravenous injections of salvarsan the symptoms all vanished. The child's father was apparently normal. The mother gave a negative Wassermann reaction, but had sensitive pressure points in the tibiæ and fibulæ while the *x*-ray showed typical gummous periostitis. She had been deaf and dumb since her sixth year (labyrinthitis?) The case seemed to throw doubt on the value of positive Wassermann in infants.—*Correspondenz-Blatt für Schweizer Aerzte.*

Book Reviews.

THE AMERICAN YEAR-BOOK OF ANESTHESIA AND ANALGESIA. By Various Contributors. F. H. McMECHAN, A.M., M.D., Editor. Quarto; art buckram; India tint paper; 420 pages and 250 illustrations. Price, $4. New York: Surgery Publishing Company. 1916.

ANESTHESIA is coming into its own. Satisfaction merely with the practice of the art without refinement of method and without investigation of the science of anesthesia is passing, thanks to some, an increasing number, of research workers and the devoted efforts of skilled anesthetists, all of which puts Anesthesia as a profession on the high plane where it belongs. The newest advance is this fine volume of over 400 pages, which collects the work of about thirty investigators in the science or art of anesthesia. The topics include the Theories of Anesthesia; Blood Changes; Peripheral Origin of Shock; Effect of Posture; Anemia and Resuscitation; Blood Pressure; Respiration in Relation to Acapnia, Apnea, and Anoxemia; Mortality Statistics; Cardiac Fibrillation under Chloroform; Delayed Chloroform Poisoning; Kidney Function; Hospital Manufacture of Nitrous Oxide; Newest Methods, as Rectal Ether and Oil, Pharyngeal Insufflation; Obstetric Amnesia, Nitrous Oxide and Oxygen, Novocaine-Suprarenin; Local Anesthesia and Various Aspects and Uses; Gasserian Ganglion Injections. These subjects, treated by such men as Lillie, Casto, Mann, Gatch, Crile, McKesson, Henderson, Miller, Levy, Gwathmey, Polak, Rice, McMechan, and Hertzler, point out the importance and excellence of the articles, each an original monograph, and the whole constituting a veritable summary of recent advances. When the Anesthetists' Societies founded a Journal of Anesthesia, in the supplement to the *American Journal of Surgery* there was produced the long-needed medium of exchange, but until now no concise year-book has appeared and it will find, no doubt, a welcome among those who want to keep at hand the information contained. It is a well printed quarto volume of impressive appearance and the able editor, Dr. F. H. McMechan, deserves great credit for his enterprise. The admission of advertisements may seem to some quite a departure, but the helpfulness of reference to apparatus mentioned is among the reasons assigned.

A MANUAL OF SURGICAL ANATOMY. By LEWIS BEESLY, F.R.C.S. Edin., Assistant Surgeon, Chalmers' Hospital, Edinburgh; Lecturer on Surgery and Operative Surgery, Edinburgh School of Medicine for Women; Lecturer on Surgical Applied Anatomy, Edinburgh Postgraduate Courses; Examiner in Anatomy, Royal College of Surgeons, Edinburgh; Lately Demonstrator of Anatomy, Edinburgh University; and T. B. JOHNSTON, M.B., Ch.B., Lecturer and Demonstrator of Anatomy, University College, London; Lately Lecturer and Demonstrator of Anatomy, Edinburgh University, and Lecturer on Medical Applied Anatomy, Edinburgh Postgraduate Courses. Price, $3.75. New York: William Wood & Company, 1916.

THIS volume gives the main facts of anatomy as viewed from their practical application in surgery. Surgical operations are described from the standpoint of anatomy rather than technique, and in order to keep the volume within reasonable bounds the descriptions of amputations have been omitted. The authors have given special attention to the anatomical relations of the joints, and the bearings of their various structures with regard to the spread of tuberculous disease. Another important feature is the inclusion of brief paragraphs on the development of the different parts. The volume is well printed and illustrated, and is of very convenient size; and it should prove a useful addition to the working library of every practitioner.

COLLECTED PAPERS OF THE MAYO CLINIC, ROCHESTER, MINNESOTA. Edited by Mrs. M. H. MELLISH. Volume VII, 1915. Octavo of 983 pages, with 286 illustrations. Price, cloth, $6 net; half morocco, $7.50 net. Philadelphia and London: W. B. Saunders Company, 1916.

THE constant increase in the amount of material contributed by the staff of the Mayo Clinic made it necessary to abstract in the 1914 volume some of the articles the material of which had been partially covered in that or in former volumes. In the present (1915) volume still further condensation has been necessary in order to keep the size of the book within reasonable limits. As in former volumes, the material is grouped under six headings. These, with the number of papers in each division, are as follows: Alimentary Canal, 26; Urogenital Organs, 10; Ductless Glands, 12; Head, Trunk, and Extremities, 16; Technique, 5, and General Papers, 15. A wide range of subjects is covered, and not only the continued studies but many of the articles on special topics are of even more than usual importance. For the progressive practitioner or surgeon, who wishes to keep in touch with the latest researches in surgery and allied branches, these papers of the Mayo Clinic are of considerable value.

PRACTICAL PHYSIOLOGICAL CHEMISTRY. A Book Designed for Use in Courses in Practical Physiological Chemistry in Schools of Medicine and of Science. By PHILIP B. HAWK, M.S., Ph.D., Professor of Physiological Chemistry and Toxicology in the Jefferson Medical College of Philadelphia. Fifth Edition. Price $2.50 net. Philadelphia: P. Blakiston's Son & Co., 916.

TO those who have had the privilege of following the growth of this work through succeeding and successful editions, the appearance of this fifth revised and enlarged edition will be a welcome sight. Developed far beyond its predecessors in size, it has come to be a complete physiological chemistry and clinical pathology combined, though of course the microscopical side of the latter subject is hardly touched upon. It is a well-planned textbook for students, and also almost indispensable for the laboratory worker. The omissions are exceedingly few, the most important being the failure to include Vogel's method for the detection of mercury in the excretions. New chapters are those on Nucleic Acids and Nucleoproteins, Gastric Analysis, Intestinal Digestion, Blood Analysis, and Metabolism. That on Blood Analysis is a striking bit of evidence of the way in which methods have developed in that one field during the past few years.

RULES FOR RECOVERY FROM PULMONARY TUBERCULOSIS. A Layman's Handbook of Treatment. By LAWRASON BROWN, M. D. Second edition, thoroughly revised. Price, $1.25. Philadelphia and New York: Lea & Febiger, 1916.

THIS little book is a valuable one to put into the hands of any patient, and a revised edition is welcome. The old days of mystery surrounding the knowledge of the physician, and of blind obedience on the part of the patient are past. This type of book is one of the last steps in the campaign of education which is being so vigorously waged. Even the most intelligent patient is going to make mistakes during the earlier part of his cure, and it is "to help the patient avoid blunders" that Dr. Brown's book was written. "It is not the author's intention that the book should be hastily read and laid aside, like the modern novel, but he believes that it should be read slowly, chapter by chapter, day by day." And taken in this dosage, it will give many a patient the needed stimulation to permanent cure. In the earlier days of cure it will help him to know why he is following certain orders, and later will be a reminder that repair is slow and cannot stand added strain. The poise with which the book is written and the absolute lack of exaggeration command respect and the work should for that reason carry more weight with those who have a long battle ahead.

SEX PROBLEMS OF MAN IN HEALTH AND DISEASE. A Popular Study in Sex Knowledge. By MOSES SCHOLTZ, M.D., Chief of Clinic and Clinical Instructor in Dermatology and Syphilology, Medical Department, University of Cincinnati; Fellow of American Medical Association, Ohio State Medical Society, Medical Academy of Cincinnati, Society of Moral and Sanitary Prophylaxis, etc. Price, $1. Cincinnati: Stewart & Kidd Co., 1916.

THIS is a conventional work, presenting the moral aspect of the problems involved in an attractive style. In a book intended for parents, teachers, and clergymen any other treatment of his subject would have been impracticable. But why push too far the analogy between male pollutions and menstruation? The former are almost always traceable to preventable causes. And why state that a youth feels better after a pollution? Not only does he suffer physical and mental depression, but a deep sense of humiliation, because of the publicity, so to speak, which invariably follows such events, the wrong interpretations and the comments based thereon. It is often the dread of pollution which drives otherwise moral youths to acts of onanism and sexual intercourse. It would have been a simple matter to have suggested measures of cleanliness in such contingencies.

Society Reports.

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS.

Twenty-ninth Annual Meeting, Held at Indianapolis, September 25, 26 and 27, 1916.

THE PRESIDENT, DR. HUGO O. PANTZER, OF INDIANAPOLIS, IN THE CHAIR.

(*Concluded from page 833.*)

Heat as a Method of Treatment in Some Forms of Cavity Carcinoma.—Dr. JAMES F. PERCY, of Galesburg, Illinois, referred to some of the historical probabilities of the use of heat in cancer, and gave briefly a résumé of his own work. In addition, he suggested the possibility of destroying cancer in the vagina, rectum and bladder by the continuous application of a bearable or a supportable degree of heat without the use of a general anesthetic. He gave this degree of heat as from 49° C. to 60° C. (120° F. to 140° F.) The author described the instrument by which the continuous heat was applied. He pointed out the difficulty of treating cavity carcinoma, especially that of the vagina, because of its usual lack of bulk or mass, as there was not enough tissue through which heat could be disseminated. If the ordinary pasteurizing temperature, delivered through the Percy cautery, was used, too much destruction of normal tissue cells might result from the treatment. If the parts were thin and the cancer disseminated, and not in mass, the author had found in two cases that the continuous application of the above mentioned degree of heat caused in one case a local disappearance of the growth, and in the other, also a vaginal case, a clearing up of the local symptoms, but not the entire disappearance of the growth which had invaded the cervix and base of the bladder. In both of these cases the continuous heat was applied, averaging eighteen hours a day in each case for six weeks. The work of the author was an effort to bring to the human sufferer from cancer the known facts in the destruction of cancer in the laboratory animal by the continuous application of heat.

Chronic Intestinal Stasis.—Dr. WILLIAM SEAMAN BAINBRIDGE of New York City said that chronic intestinal stasis, or what he had often termed defective human plumbing, was increasingly being accepted as one of the fundamental causes of disease. Gradually the profession was coming to consider the condition as an entity, with far-reaching results. Many of those to whom stasis and constipation were at one time synonymous were broadening their viewpoint and learning that there might be residual intestinal content doing damage to the entire organism, regardless of whether there were activity of the lower bowel or not. This was evidenced by the fact that some of the worst cases of stasis occurred in those with diarrhea. Unfortunately, in the minds of many of the profession (happily their number seemed rapidly diminishing) intestinal stasis had been thought to indicate only one kind of treatment—the removal of a large portion of the intestine with its consequent extreme surgical risk. Those who had given thoughtful attention to the teachings of Lane and others were recognizing the truth of the oft-repeated statement that the vast majority of all cases of chronic intestinal stasis belonged to the physician, through whose prompt and proper care the necessity of seeking ultimate relief at the hands of the surgeon would be obviated. Between this overwhelmingly large group and the relatively small number of neglected patients (those late in the disease, or previously treated by improper or inadequate surgery) who must have part of their plumbing removed in order to attain comparative health and not drift into chronic invalidism with attendant complications which might terminate life, there remained a mid-group. In these cases a careful application of conservative surgery to the abdomen, according to the principles of the mechanics of the intestinal canal, returned the patient to the first group, where with medical care and reasonable attention to hygiene and dietetics, he could be restored to health and strength. The writer, who had been for many years a close student of body plumbing, had published from time to time articles covering various phases of the subject of chronic intestinal stasis. It was his purpose in this and a number of subsequent papers to report succinctly a series of case histories illustrative of various types of stasis treated surgically and, though brief, it was hoped these would comprise the essentials in such manner as to present a sufficient ground work upon which to base conclusions. "Evidence was and must be the test of truth"; as it was only by weighing the evidence in relation to methods of treatment that medical progress was possible, it was hoped that case reports which gave actual results—good, bad and indifferent—might serve to facilitate this end.

Tuberculous Glands of the Mesentery.—Dr. ARTHUR T. JONES of Providence, R. I., drew these conclusions: "(1) Tuberculosis mesenteric glands are often a primary disease of the true tuberculous type. The bovine type was undoubtedly present in many children and without producing symptoms, the glands remaining quiescent, or having a tendency to subside. (2) It is impossible to make a correct diagnosis before operation, as a rule, unless there are palpable glands which may be felt through the abdominal wall, or by the finger in the rectum. (3) Tuberculous mesenteric glands may be present without giving symptoms. (4) There are two clinical types: (*a*) A slightly progressing one generally with palpable glands; (*b*) An acute fulminating type most often stimulating and impossible generally to differentiate from appendicitis. (5) Prognosis in the subacute stage is good without operation. In the acute stage exploratory laparotomy should be done, but the glands should not be removed unless there are definite indications either from adhesions, ulceration, or size of mass producing pain or much obstruction. (6) Tuberculous glands of the mesentery may not present any symptoms until breaking down begins in the glands, after which we get our symptoms of tuberculous peritonitis, intestinal obstruction, or symptoms simulating acute appendicitis. (7) In children and young adults with history of righ-sided abdominal pain, with or without palpable masses, tabes mesenterica should always be considered as a possibility."

The Relation of So-Called Ether Pneumonia to Pelvic and Abdominal Surgery.—Dr. WILLIAM EDGAR DARNELL of Atlantic City stated that for many years it was commonly taught that ether irritated the bronchi and was largely the cause of what was known as post-operative pneumonia. Such pneumonia was spoken of, and still was in most hospitals, as "ether pneumonia." Yet any surgeon in reviewing his experience might find many facts to disprove, and few or no reasons to prove that ether was the cause of pneumonia after an operation. Ether was administered in most hospitals many times every day, yet the condition known as ether pneumonia was a rare occurrence compared with the number of ether administrations given. If the pneumonia were the result of the ether, we ought to expect to have many cases every week. Again, if ether produced all the havoc it had been credited with, the administration of it by the intratracheal method might almost come under the classification of criminal malpractice. Yet we knew that this was done safely every day. Rovsing had proved experimentally that although ether did occasion increased secretion of the salivary glands of the mouth, that the larynx and trachea and the bronchi were not irritated at all, even when the animals were killed by administering ether through a tracheotomy tube until they were dead. The only way, therefore, that ether could produce pneumonia was by the aspiration of the accumulated saliva in the throat, usually the result of technical error on the part of the anesthetist, who should not allow the secretion to accumulate in the throat. Such secretions might, of course, be easily infected from the buccal cavity. It was quite possible under such circumstances that tonsillar infections, involvement of the nasal accessory sinuses or the teeth might be one of the causes of post-operative pneumonia which had been attributed to ether. Attention had frequently been called to the importance of the sanitation of the nose, throat, and mouth before all operations. If we looked on pneumonia after an abdominal operation just in the same light as we did the development of a subphrenic abscess after an appendectomy, they bore the same analogy to the point of original infection. The only difference was that in the one case the new focus of infection landed above the diaphragm, and in the other beneath it, but both were brought about by the carrying of infection from the original source in the abdomen up through the lymphatics and veins by the retroperitoneal route. The idea was further strengthened by the fact that most post-operative pneumonias would show a mixed infection containing streptococci, colon bacilli, or other organisms in addition to pneu-

mococci. On the other hand, it was often true that the appendix, the gall-bladder, the Fallopian tubes and the ovaries might be the seat of a pneumococcus infection.

It would seem proper to conclude, therefore, that cases of pneumonia following operations were not due to the ether. The term "ether pneumonia" should be discarded and forgotten Post-operative pneumonia occurred with great rarity except after abdominal operations, and was then probably due to an infection already existing in the bronchi or lungs at the time of operation, or to imperfect aeration and ventilation of the lungs by reason of the fear of taking deep breaths after a laparotomy, but most often such pneumonia was a secondary infection of the lung following a septic abdominal condition.

Hospital Management and Mismanagement. — Dr. GORDON K. DICKINSON of Jersey City discussed the fundamental origin of all hospitals. There was no proper definition of the term. There were three essential factors: Patients; attendance by physicians and nurses; superintendent and the board of managers. From the viewpoint of the first he discussed therapy, diagnosis, and education; from that of the second came system, red tape, economics, and autocracy. From the third, the board of managers, made up entirely of the lay public, came ignorance of the needs and the ideals of the institution, often working solely through the superintendent, who had made a home of the hospital for himself. We looked for finances and encouragement, but the results were disheartening.

The Surgeon's Responsibility to the Economics of the Hospital.—Dr. EMERY MARVEL of Atlantic City said that a mutual dependence existed between the hospital and the surgeon. This relation imposed upon the surgeon the duty of guardianship for, and a responsible duty to the institution. He became, in part, responsible for the waste and abuse of its resources. He was directly responsible for loss of service and embarrassment to the organization when late for operation, dressings, or other appointments; the waste in using unnecessary or unduly expensive supplies, and for misuse of funds occasioned by encouraging expenditures for construction and equipment which did not give commensurate beneficial returns. A staff surgeon must share responsibility for the neglect to utilize opportunities which, if taken advantage of, would benefit the hospital. It was his duty to inspire enthusiasm in attendants, maintain a congenial atmosphere for the patients and to teach improvements in service. It was the surgeon's opportunity to teach the patient better care for self and give him knowledge to prevent recurrence of disease or injury. His opportunities for service to conserve the institution's interest were many, and his responsibility proportionate.

Removal of the Appendix for the Cure of Trifacial Neuralgia and Other Nerve Pain About the Head and Face.—Dr. MAURICE I. ROSENTHAL of Fort Wayne said that the apology which he had to offer for presenting this very brief report of only seven cases was the startling results obtained. He did not claim in this small experience that he had established a new pathology for trifacial tic and kindred affections, but he did claim that in these seven cases he had fixed the pathology in the vermiform appendix, even though the physical and subjective evidence of appendicitis was so obscure as to be entirely overlooked. In all but one case there was present almost symptomless chronic appendicitis of the obliterating type; the other a symptomless pus case. It was very probable that a report of 100 cases might reveal some further startling results in recurrence and might explain the unsatisfactory results from resection or revulsion of the nerve as well as from injections used with a view to chemical nerve destruction. Case No. 7 of this series was more on the order of migraine or so-called sick headache. It had not been uncommon in his experience to note the cure of migraine and so-called sick headache after removal of a diseased appendix. It was quite possible that many of these cases came under the same pathology as did tic dolourreux and other nerve pains about the face and head. From the prompt cessation of the pain in six of these cases we might conclude that the disturbance was a toxemia with selective action. If the tonsils, the teeth, the hollow bone cavities gave rise to toxemias and bacteriemias of such far-reaching effect, we need not be surprised if the appendix, a hollow abdominal organ with its possibilities of aerobic and anaerobic bacterial development, should also give rise to a toxemia which might readily be the basis of a selective neuritis or nerve irritation.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Sixty-sixth Annual Session, Held at Scranton, September 18, 19, 20, *and* 21, 1916.

(Special Report to the MEDICAL RECORD.)

(*Concluded from page* 831.)

SECTION OF SURGERY.

Chairman's Address. — The Chairman, Dr. LEVI J. HAMMOND of Philadelphia, stated that he hoped that he should have met in some sense his obligation, when he had reminded the members of the Surgical Section, for he was sure he was doing nothing more, of the great principles which this Section stood to promote. He said that we were in a time of unusual stress and test. There never had been a time, therefore, when we needed more clearly to conserve the principles for which this Section stood than the present time. That part of the world from which our inspirations, if not our methods, had in the past been drawn seemed for the present in the cauldron. Just what the outcome of this gigantic ebullition was to be no one dared at present even prophesy. We stood apart, as yet, unembroiled, conscious of nothing so much as our own powers, resources, and possibilities. There must be no difficulty so great, no truth so obscure, no problem so involved that the American surgical mind could and did not solve.

Symposium on First Aid—The Railroad Phase.—Dr. J. B. HILEMAN of Harrisburg read this paper in which he stated that the problem of first aid on the Pennsylvania Railroad has been to provide a simple dressing applicable to railroad conditions and to instruct the employees in its use. The first aid packet was air and moisture-proof, and was distributed in tin boxes which held six. On the outside were printed instructions for its use and a tag bearing an order for a fresh box as soon as the seal was broken. These packets were put wherever they might be of use. Stretchers and blankets were supplied to all baggage, mail, express and work cars, stations and shops. Employees were taught to confine themselves strictly to first aid, and in severe cases to send for the nearest physician. The dangers of infection and hemorrhage were pointed out. No drugs or whiskey were to be given. Employees were taught to effect resuscitation from electric shock by means of the Schäffer method. His rather extensive experience in first aid taught him that employees were keen in appreciation of this subject and did their best to put into practice the instruction they got. The results had been most satisfactory.

Injuries Common to Policemen and Firemen and Their First Aid Treatment.—Dr. HUBLEY R. OWEN of Philadelphia read this paper, saying that the common injuries to firemen were punctured and lacerated wounds, due to falling glass, treading on pointed objects, kicks and bites of horses, falling bodies, blows by harnessing apparatus; scalds and burns by hot water, steam or acid; asphyxiation by the great variety of smokes and fumes met with fractures and sprains; traumatic hernia. Injuries common to policemen were those due to being struck by prisoners, wounds of the fingers from striking prisoners; gunshot wounds, fractures, especially of the jaw from being struck; dog bites. The principles of first aid treatment of injuries were to stop hemorrhage, keep the wound clean and put the part at rest. The army tourniquet was used; wounds were swabbed with iodine. An immunizing dose of antitoxin was given in all punctured wounds; only one case of tetanus had developed in the first department since 1871. In shock morphine was used freely. Whisky was not a good remedy for smoke cases. Six pulmotors were in use in the first department.

Dr. J. B. CARNETT of Philadelphia said that unfortunately it was not often possible to have at the scene of accident the surgeons, ambulances, pulmotors, stretchers and the various other equipment described by Dr. Owen, as being sent out with the Philadelphia fire fighters. The fact that more than a million serious accidents occurred each year in the United States urgently demanded more widespread knowledge of first aid. A great many lives had been saved each year by the prompt application of first aid, and many more could have been saved had the principles of intelligent first aid been more generally known. It had been urged against the universal teaching of first aid that "a little knowledge is a dangerous thing." It was no doubt true that in exceptional instances first aid teaching, when

perversely applied, might lead to meddlesome surgery or even to disastrous results. Such deplorable instances, due to deficient knowledge, fortunately were rare and were overwhelmingly counterbalanced by the great number of lives that were saved by intelligent first aid attention. First aid, which thus far had been taught chiefly by the National Red Cross, military and municipal organizations, Boy Scouts and various corporations, had proven of such vital and practical value that it should henceforth be included among the subjects taught in the public schools.

Dr. W. F. Skinner of Chambersburg said that one of the first principles in applying treatment to wounds was that Nature was the best healer, and, if not interfered with too much, she would bring about a reasonably good result in her own way and in her own time. He felt that it was as important to know what not to do for wounds as it was to know what to do. With reference to burns generally, he felt that a good rule to follow was the washing of the parts with castile soap and warm water, using pledgets of cotton for the removal of foreign matter and then applying the normal salt solution, heavy dressings of gauze and parchment paper.

Dr. A. W. Colcord of Clairton said that he wanted to say a word on applying the tourniquet. He always emphasized that there were three methods of applying the tourniquet: on the artery, the vein and the capillary. The tourniquet must never be made tight enough to stop hemorrhage, only the spurting from the wound, and, when spurting was stopped, they must stop tightening the tourniquet. The remaining hemorrhages must be stopped by direct pressure on the wound. He placed the iodine treatment for wounds as the best for application at the roadside, the private home, hotel, or anywhere outside of the hospital. In emergency hospital work he did not believe the iodine treatment was best. He believed the constant wet dressing was the best. This was made of saturated solution of boric acid one-fourth and alcohol three-fourths. They put it directly to the wound and applied plenty of cotton. In several thousand cases they had not had a primary infection.

Dr. Edward Martin of Philadelphia said that the emergency which was commonest was not the fatal hemorrhage, or the discrimination between uremia, apoplexy, heat exhaustion or sunstroke which was to be done so surely in the books for the laity and which we ourselves so often failed to make, but infection, and to the credit or discredit of the profession, which ever one might choose to regard it, there was no concerted view as to how infection should be treated in emergency. There was no concerted view as to emergency dressing. It was time to formulate our knowledge.

Dr. H. R. Owen of Philadelphia said that they tried to teach firemen and policemen to do as little as they could. They carried first aid packages, and the policemen were taught to place a compress on the wound and tie a two-tailed bandage around. They had a very complete system of having wounds treated, using an ampoule of iodine. In regard to punctured wounds the firemen practically felt their jaws begin to tighten as soon as they received a punctured wound, and they reported at once for antitetanus serum.

Modern Hospital Organization in Rural Pennsylvania.—Dr. H. L. Foss of Danville presented this paper, in which he stated that Pennsylvania, with a population of about six million outside of the large cities, had about 150 hospitals good, bad and indifferent. Fully 90 per cent. of these had no trained laboratory workers; not over 20 per cent. of them were prepared for *x*-ray therapy or fluoroscopy. Whenever a young member of the staff attempted to develop a laboratory he received such poor co-operation that he soon became discouraged. The recent requirement of an interneship of one year on the part of those applying for license to practice medicine had led to great improvement in these conditions. Certain positions in order to get the best service required the incumbent be on a fixed salary. Staff appointments should be only on merit. The success of the rural hospital would depend largely upon the education of the people and to a great extent upon the training of the general practitioner on whom rested the initial responsibility in making the diagnosis and recognizing the need of hospital care. In addition to this the principal factors in success were dependent upon a clearly defined need for a hospital in the community; the construction of an adequate and well-equipped institution; a sound financial basis; a competent and efficient administrator who would see to the maintenance of high standards in the staff; a broad sensible policy, giving the hospital executive full authority and responsibility in which he would have the complete support of the trustees; thorough and scientific care of the sick; individual investigation of the financial resources of all patients and discouragement of indiscriminating charities; an efficient system of purchasing, so arranged under the direction of the institution's superintendent that he might be free to take advantage of all changes in price.

Dr. T. B. Appel of Lancaster said that in opening the discussion of the very important question of a hospital for the rural districts he wished to emphasize the fact that we should all agree on the importance of the development of the laboratories. He wished to say personally in relation to the hospital with which he had connection that the inspection there had made the efforts of the staff to increase the efficiency of that hospital so very much easier than before they had been told where they were deficient. The modern hospital, particularly in a small town, was in a sense an educational institution for the profession. These institutions should become centers of education for the profession in that neighborhood, that they might have an opportunity to see the advantages or to use the advantages of modern hospital care for patients.

Dr. A. R. Allen of Carlisle said that the present Board of Medical Examiners had done more to elevate the medical profession and bring the hospitals up to the standard than all the work done heretofore in Pennsylvania or in any other State. He wanted to compliment the chairman and the members of the Board for the great work which they had done in efficiency and increasing the good instruction the young medical men get before they were licensed to practice medicine.

Dr. William H. Walsh of Philadelphia said that he wished to express his appreciation of Dr. Foss's paper. He also felt that Dr. Baldy had done a great deal for the hospitals of Pennsylvania. A great deal of the opposition he had came from members of the staff of the hospitals. The improvements he recommended should have been realized years ago. In reference to the appointment of staff officers, that was a vital matter.

Dr. Frederick L. Van Sickle of Olyphant said that he thought a rural hospital to-day was confronted with a question which had not appealed to it so strongly in the past in relation to the newer developments of surgery and medicine which were to come under the head of sociologic or workmen's insurance. Employers were trying to get men and women cured in medical cases, and it appealed to the sense of the manufacturer, the mine and mill owner, when he was willing to pay somebody well to get the sick man cured. Therefore, the efficiency of the smaller rural hospital must be increased and the men doing the work must be up to the standard.

Dr. John B. Roberts of Philadelphia said that some things must be obtained for efficiency. First, a permanent medical dictator. Somebody must be on duty as a medical men and have control from the 1st of January to the 31st of December at 12 o'clock at night. The damnation of small and large hospitals was the fact that nobody was boss, and every man who came on duty every six weeks ordered something different. The form of treatment must be a standard which everybody must obey.

Dr. J. M. Baldy of Philadelphia said that the matter rested with the staff of the hospital. If they arose to the opportunities that had now come to them for the standardization of their institutions the State board would be patient. As medical men they had a unique opportunity to awaken interest, and he felt that if they did not measure up to these responsibilities eventually that the shame of it should come on our own heads. The unequal development was one of the crying evils of this State. They found in their inspection that from 75 to 80 per cent. of the work done in the rural districts was surgical, and that of that about 75 to 80 per cent. was emergency. He would like to know how the Bureau of Medical Education and Licensure could send an interne into such a hospital for his fifth year. If this condition was altered such institutions would simply get a credit for second or third year interneship and be classified as special hospitals.

The Treatment of Deformed Union and Non-union of Fractures.—Dr. John B. Roberts of Philadelphia read this paper, saying that deformed union of bone was usually due to lack of knowledge of efficient treatment of the fracture or to neglect in applying well-known mechanical or physical principles to the problem of treatment. Operative exposure for remedying de-

formed union of bone was demanded in only a limited number of cases. Subcutaneous refracture for the correction of angular deformity was comparatively easy. This procedure was available and successful for a long period after the fragments had been firmly united. After-treatment was on the same lines as in accidental fracture. Repair in delayed union should be hastened by massage, good food, air, and surroundings, and the interrupted use of constriction with a rubber band at the proximal side of the fracture. There should not be too hasty resort to operation in non-union. Using the limb and rubbing the ends together by manipulation, also injection of blood hypodermically into the tissues around the fracture, was helpful. When these measures failed operative treatment was demanded.

The Treatment of Compound Fractures.—Dr. JONATHAN M. WAINWRIGHT of Scranton read this paper, in which he stated that the main problems presented by compound fractures were to prevent or cure infection and to procure and maintain satisfactory reduction. The more important of these was infection; indeed, it would be better if we substituted for open and closed fractures the terms infected and uninfected fractures. Very few infected fractures were restored to even a near approach to normal. Researches in the armies in Europe had shown that Dakin's hyperchlorous acid solution was most effective in the treatment of infected fractures. These studies had also shown that the retentive fracture dressings must be such as to permit access to the wounds for the purpose of dressing. As regards drainage, we must accept the teaching of Moynihan, namely, that there "never yet was such a thing as a gauze drain." He believed that the fixation methods would narrow down to three: open operation and suture of the fragments by kangaroo tendon, the Albee sliding graft, or extension by the Steinman pin.

Dr. JOHN B. LOWMAN of Johnstown said that he thought the treatment of fractures was a very serious proposition. Very many angles should be considered before doing operation, and before doing it you should be perfectly satisfied in your own mind that you should do it. He had not been so successful as Dr. Roberts with these old fractures of four or five months by breaking them. He thought the success of the treatment of compound fracture lay in the primary dressing. In compound fracture too much was done in the way of first aid. You ought to let them alone. In their mills at home in a fracture nothing was done at the time except to put on a clean piece of gauze and the patient sent to the hospital immediately. Their men were instructed never to pull a fracture. He thought the thing to do was to convert the compound ino a simple fracture before attempting any method of operation. The thing to do was to wipe all the foreign material off you could and paint with iodine and put on a dressing. Their success with compound fractures by practically letting alone had been that their percentage of infections had become very low. He did not think any plate should be put on a compound fracture.

Dr. WILLIAM L. ESTES of South Bethlehem said that he was beginning to be in the position in which he dreaded to see a fracture. He believed that the indication in the compound fracture was, first, as the reader of the paper had said, to provide for as nearly absolute drainage as possible. He thought they might all conclude that a compound fracture was an infected wound when it came in. If these fluids which develop were dammed up they would inevitably press on the blood-vessels and a thrombus develop, and, if it continued, a necrosis. The indication then was to relieve that pressure as soon as possible and to prevent it. As absolute drainage as could be should be used. The great principle enunciated by the reader should be remembered, namely, that gauze was not a drain. One must provide tubular rubber, bone, or what not. He thought, too, that he was not quite in accord with the dictum that metallic plates should not be used. He persisted in using metallic plates with the greatest satisfaction. Speaking of rest, he thought we sometimes carried that principle too far. He did not believe that absolute immobilization was necessary for the union in fracture. He thought he had seen delayed union caused from immobilization. Certainly cases of delayed union had seemed to yield to use.

Dr. EDWARD MARTIN of Philadelphia said that, as a rule, a fracture united in proportion to the traumatism which had been inflicted. The greater the traumatism and larger the exudate, the slower the union. There seemed to be almost no constitutional condition which would either delay or interfere with the union of fracture. They had had the best results in those cases of delayed union by the Bier condenser and by the simple common-sense expedient of changing the treatment. Excepting in the operative cases, tney were not greatly troubled with non-union or greatly delayed union. In contravention of what had been said, it seemed to them that every case of fracture operated on whether by kangaroo tendon, bone plates, pins, pegs, staples, screws, unless there was some delay in union and the delay was proportionate to the traumatism inflicted on the end of the bone, they were to some extent led from the ideal of opposition.

Dr. CHARLES E. THOMSON of Scranton said that 50 per cent. of their compound fractures healed without marked infection with ordinary first dressings, or, if infected at all, the infection was negligible.

Dr. G. F. BELL of Williamsport said that in the large majority of cases that were infected it was due to the fact that the surgeon went into the operative field before proper aseptic preparations had been made. In the simple operation of necessity in these compound fractures one had to open up the field to see what blood vessels and muscles were torn, what fragments of bone were comminuted, or to see what muscles were between the fragments, which no surgeon could see and which no *x*-ray would show.

Ligation of the Superior Pole of the Thymus in Operating for Goiter.—Dr. LEVER F. STEWART of Clearfield read this paper, in which he said that about 30 per cent. of the cases of toxic goiter operated upon were either not cured or were not helped in any way. There were cases of Basedow's disease in which the thyroid alone was responsible, and others in which both the thyroid and the thymus were responsible. In dissections which he had made, in the majority of cases the inferior thyroid arteries gave branches to the superior pole of the thymus. In some instances this branch was given on only one side. In one out of ten cases no such branch was given off. Ligation of the inferior thyroid artery close to the gland did not touch its branch to the thymus. As a result the thymus might become congested and enlarged. Ligation of the superior pole of the thymus would circumvent this and in addition have a favorable influence upon the thyroid participating in the disease.

Dr. DONALD GUTHRIE of Sayre said this paper of Dr. Stewart's opened up a new line of reasoning. He thought, after all, that those who had done thyroidectomy in which either one lobe or part of one lobe had been taken out and where the inferior arteries had been taken out had been worried for the first or second day by a lot of pressure symptoms, and it was his belief that some of these cases might be suffering from an engorged thymus.

Dr. G. T. MATLACK of Wilkes-Barre said that in his experience in doing thyroidectomy it was very rarely he saw the enlarged thymus glands. He had removed three enlarged thymus glands, but not in exophthalmic goiter. It was a very hard thing to find an enlarged thymus gland when operating for goiter. He was looking for it all the time and did not find it. He believed we would have to give the thyroid credit for most of the evils.

Dr. CHARLES H. FRAZIER of Philadelphia said that he felt disposed to take the view that Dr. Matlack had taken as to the importance of the thymus gland in the intoxication we saw associated with the enlarged thyroid. He knew in the literature we found cases which were extraordinarily important in pointing in the other direction. He personally had not found them in his clinic and he had been lookng for them, having most of the patients fluoroscoped, but had not found as yet any coincident enlargement of the thymus gland in thyrotoxicosis.

Dr. GEORGE C. JOHNSTON of Pittsburgh said that the relation between the thymus and thyroid in cases of thyrotoxicosis was a very doubtful one. Practically he believed there was little connection. Lots of these cases of undoubted thymus were diagnosed as aneurism or mediastinal tumor, but if you put the patient in the recumbent posture you would find the thymus drop over and give the shadow of a dog's ear. It was such an unusual thing that it was absolutely diagnostic.

Support of the Stomach After the Beyea Gastropexy.—Dr. T. TURNER THOMAS of Philadelphia presented this paper, in which he said that Dr. Beyea's operation was the only one which hung the stomach in its normal, physiological position. All others attached the stomach to the anterior abdominal wall, so that it then hung in an abnormal position. Full credit had not been given to

the reported success of the Beyea operation, because it had always been claimed that the stomach afterward hung by the shortened gastrohepatic omentum, which was obviously too weak a structure to support such a weight. The His models, patterned after frozen bodies with the organs in their normal positions and formalin hardened bodies, proved that in life the anterior and upper surface of the stomach and the under surface of the liver were in close, intimate contact over a wide area. The effect of the Beyea operation, therefore, was to cause the development of strong, supporting adhesions in this area of close contact. Such close, strong adhesions were found in a patient reoperated on after a preceding Beyea operation. Therefore, the support of the stomach after the Beyea operation was ample for all needs and the stomach was in the best possible situation.

Dr. H. D. Beyea of Philadelphia said that while Dr. Thomas sought to form adhesions between the stomach and liver, he tried to avoid them. He scarcely retracted the liver to any great extent. The operation he did originally was the suture of the gastrohepatic omentum. He didn't think he ever got the stomach sufficiently high in the original operation. He now placed four sutures through the hepatic omentum and tied them, and this brought this in contact with the lesser curvature of the liver. Then inflammatory reaction took place with the formation of further adhesions. He had operated upon more than fifty cases. He had made no statistical study for the last two or three years as to the results. Up to that time 90 per cent. had gained in weight.

Dr. G. M. Dorrance of Philadelphia said that this tissue which Dr. Beyea spoke of was on the under surface of the liver and was very strong. It runs from the transverse fissure to the oesophagus. In thirty-four fresh cadavers they had found this band, and by suturing the stomach in the method he described and fastening scales to the bottom the stomach would stay up with 14 to 16 pounds' downward pull. Dr. Thomas did not take up the indications. There was practically only one indication, acute wrinkling of the duodenum, for this operation. If motility was good the stomach might be down in the pelvis and still empty itself.

Dr. T. T. Thomas of Philadelphia said that he believed strongly in the Beyea operation. There must be shown some other method than that conceded by Dr. Beyea by which the stomach was held up or the Beyea was not a rational operation. He thought he had shown clearly from the normal anatomy of the part that that operation cannot be done in any without the development of a considerable area of adhesions between the stomach and liver, which would be very much stronger than the gastrohepatic omentum ever was.

Obstruction of the Common Bile Duct.—Dr. C. D. Schaeffer of Allentown read this paper, in which he said stone was the usual cause of obstruction in the common bile duct. Stones were seldom found in the common duct, but came down into it from the gallbladder. They seldom caused complete obstruction; when the obstruction was incomplete there was a ball-valve action, as described by Fenger, which was attended by pain, irregular chills, followed by high fever and sweats, and later on by intensified jaundice. If the obstruction was in the ampulla of Vater or at the orifice of the papilla, bile might be retrojected into the pancreas, an occurrence which was followed by acute hemorrhagic necrosis of the pancreas. If the obstruction was due to a polyp, the health became impaired insidiously and there was progressive jaundice, persistent intestinal indigestion, and emaciation. The earlier the operation was done the more favorable the outcome. In cancer the operation must be done so early as to permit complete excision of the growth; if this could not be done, cholecystenterostomy might prolong life. Resection of the bile duct most suitable in the structural type of obstruction was attended by a mortality of 50 per cent.

Cholecystectomy the Operation of Choice.—Dr. A. R. Matheny of Pittsburgh read this paper, in which he said that as the work of Rosenow showed gallstones was not a disease per se but always a sign of a previously diseased gallbladder which, once diseased, either remained a nidus of infection or, as a result of inflammation, lost its function, it was probable that the gallbladder was simply a pressure chamber; but, even admitting that it was a storage reservoir, this function was nullified in cholecystitis. Therefore, given an organ whose function was impaired or destroyed and whose presence was a source of infection, it was reasonable to remove it if the risk was no greater than drainage would be. The mortality in the experience of several good surgeons in the past two years had been no greater from cholecystectomy than from cholecystostomy. From the point of view of end results, there could be no question that removal of the gallbladder showed less morbidity than did drainage. If we would remove the gallbladder, except where it was necessary for drainage, we would avoid the unpleasant experience of an unimproved patient and removal of the gallbladder by another surgeon.

Dr. J. A. Lichty of Pittsburgh said that Dr. Matheny had brought out a very interesting point in gallbladder disease which was not thought of when he began to compile his statistics upon gallbladder work. Several years ago he collected statistics covering twenty or twenty-two years. In the early part of that time, when the gallbladder was removed there was very little thought of it and he made no effort to compare cholecystectomy and cholecystostomy. At that time he published some 614 cases, and 193 of these were operated upon; 174 were gallstone cases, and drainage was done in most of these. Two of these had to be operated on on account of failure of the operation. Cholecystectomy had to be done. He recalled in his early cases one very satisfactory cholecystectomy. The question was whether the results would be comparatively good. He would rather have a live patient with the gallbladder in than a dead patient with the gallbladder out.

Dr. Ernest Laplace of Philadelphia said that only one reason stood in the way of removing the gallbladder, the supposititious one that it was a necessity to functionating of proper digestion. It had been proved that it was not. Therefore, why preserve an organ that was not of essential use to the system? He removed all gallbladders, every one and without exception, and only hesitated when the necessary time required for proper work might jeopardize the life of the patient. Not that he feared the after results, but that the doing of this operation in the correct way at the time did not seem possible.

Dr. J. H. Jopson of Philadelphia said that he found himself very much in accord with Dr. Matheny's views in the indications for the removal of the gallbladder. When he began to remove gallbladders the mortality of cholecystectomy was higher than cholecystostomy. With the improvement of technique he found the mortality was no more than in cholecystostomy and end results were very much better. He was still taking out gallbladders which he formerly drained. He thought when a gallbladder was acutely inflamed and patchy with gangrene, as in some cases of acute pancreatitis, or in occasional cases of infection of the gallbladder, we had better let it alone.

Dr. H. L. Foss of Danville said that there was no question about the value of cholecystectomy, as there were cases where there was a history of recurrence of stone. He recently performed a cholecystectomy on a patient operated on three times before for gallstones. When the gallbladder was removed he counted over 500 shotlike stones. That patient had been drained three times before.

Gastric and Duodenal Ulcer from the Study of Twenty-five Operative Cases.—Dr. H. B. Gibby of Wilkes-Barre read this paper, in which he said that the most common evidences of ulcer in his cases were pain coming on one-half to three hours after meals and progressive emaciation. The painful attacks were recurrent and sometimes morphia was needed for relief. Basing his opinion upon the etiology and pathology of ulcer, he would say that an ulcer cannot be permanently cured by medical treatment. Surgery met the requirements of a cure. The proper method of operation in gastric ulcer was either excision, if the ulcer was large, or destruction with the Paquelin cautery, if small, combined with gastroenterostomy. For duodenal ulcer his results had been good from folding in the hardened area with mattress sutures and doing posterior gastroenterostomy. In his series 88 per cent. had been relieved of soureructations and a like number of abdominal distension. In view of the results obtained, operative treatment seemed logical and justifiable.

Dr. H. D. Gardner of Scranton said that three or four times as many ulcers of the duodenum would be found as ulcers of the stomach. In operating make your incision under local anesthesia. In favorable cases you could do all your work in this way. In the more difficult ones you could make your diagnosis and plan your work, which often took half the time.

Dr. F. P. Ball of Lock Haven said that he was more and more convinced that gastric ulcer was much more common than was formerly supposed. If one looked for it he was much more likely to find it. More than four times as many cases of ulcer were found at autopsy as

were diagnosed before death. This would indicate that we were missing the diagnosis in a great many of these cases. The history in a good many cases was so indefinite and the symptoms so obscure that we could not make a positive diagnosis.

Dr. J. A. LICHTY of Pittsburgh said that when it came to chronic peptic ulcer he had the opinion that it was a surgical condition. That would mean that every patient with a chronic peptic ulcer should be operated forthwith. That was not altogether in the interest of the internist. But the patient was one party in the procedure, and it was not always possible to bring patients to operation. The indications for operation in peptic ulcer were very definite. For the last two years it had occurred to him that he was seeing quite a number of patients who had been operated, and it was a most discouraging thing when you took a history of chronic appendicitis and thought you would take the patient to the hospital, and before you got through he would say: "Two years ago I was operated upon and had my appendix taken out." Among 1400 patients of all kinds he had seen 126 cases who had beautiful ulcer histories and good operation, beautiful appendix histories and careful operations, and yet their symptoms continued; so surgery did not appeal to us so tremendously in these doubtful cases when we had experience of that kind.

The Value and Limitation of Radiotherapy in Gynecology.—Dr. F. E. KEENE of Philadelphia read this paper in which he said that his report comprised an analysis of 116 cases treated in the gynecological department of the University Hospital; 69 cases were of malignant growths of the vagina, cervix or urethra, and 47 cases of benign hemorrhage of myomatous or myopathic origin. The majority of cases received 85-110 mgms. for 24 hours. In one case of cauliflower growth in a woman of 28 who was six months pregnant 210 mgms. were applied with complete cure. The only immediate effects were nausea and vomiting which usually ceased 24 to 36 hours after removal of the radium. In 44 per cent. of cases of cancer there was complete healing and in only 2 cases was there no benefit. In not a single instance had there been a failure to check bleeding in the cases of benign hemorrhage. Mild symptoms of menopause were developed in 10 cases. In cancer of the fundus, operation was preferable to radium; this was also true of early cervical cancer. In cases of small myoma whose only symptom was hemorrhage 100 per cent. of cures might be expected. This work was still on probation.

Dr. H. K. PANCOAST of Philadelphia said that he had kept in touch fairly well with this work and could indorse all that Dr. Keene had said. The gynecologist had the advantage over the Roentgenologist in that he was able to use this agent himself; whereas the Roentgenologist was usually not a gynecologist. There were undoubtedly some advantages in radium over Roentgen rays in this one feature. The results of radium therapy in carcinoma of the cervix could not be classified as cures as yet because the longest cases had yet almost three years to run before they came within the five year period. There were cases in which a combination of radium and *x*-rays might do good, the radium not being quite strong enough to reach the outer border of the growth.

Dr. GEORGE C. JOHNSTON of Pittsburgh said that the disadvantage of this treatment was that it required the physician to have anywhere from $10,000 to $25,000 worth of radium. Also this work required considerable experience and a careful technique and the results which these gentlemen had so beautifully described might not be expected to follow the application of radium without regard to the case. Where simple hemorrhage was encountered aside from malignancy, these cases were controlled with mathematical exactitude by deep Roentgen therapy. He made that statement without any qualification whatever.

Advantages of Local Anesthesia. — Dr. HARVEY F. SMITH of Harrisburg read this paper in which he stated that patient and persistent use alone could train a judgment as to the limitations of local anesthesia and the type of cases in which it was indicated in preference to general anesthesia. The possible disadvantage might be noted as follows: The operative field could always be completely anesthetized or the mental attitude of the patient might not be right. However, the fact that painless surgery could be done without ether was becoming more widely known by the laity and converts to this method were usually easily made. Too much enthusiasm with too little judgment might lead to inexact or incomplete surgery. The question of additional time required for operations under local anesthesia was regarded by some as an objection. This was only relative and should hardly be considered valid. The advantages might be briefly summed up as follows: The novocain and adrenalin combination when injected in proper solution and with correct technique was absolutely safe. This was his personal judgment as well as the judgment of all users. There was a minimum of surgical shock and encroachment upon the patient's margin of safety; rarely was there vomiting, neither was there ether toxemia to overcome. Because of these facts the patient entered promptly upon a smooth and comfortable convalescence. There was prompt and, he believed, better wound healing due to the sharp dissection and gentle handling of the tissues. Moderate toxemia might occur, but no serious heart, lung, gastro-intestinal or kidney disturbance seemed to follow the use of novocain. Office and ambulatory surgery was simplified. Postoperative pain was less in abdominal cases if a 1/6 per cent. solution of quinine and urea was injected around the field of operation. This caused an edema of the tissues which was not serious if the suturing was not too tight. Weighing these limitations against the advantages and possibilities he felt that we could fairly say that novocaine anesthesia, plain or with one of the possible combinations, should be used when the operative field could be completely anesthetized and the mental attitude of the patient was right or when the vitality of the patient was low and the margin of safety was narrow and a minimum post-operative shock was regarded as a factor necessary for recovery.

Dr. J. TORRANCE RUGH of Philadelphia said that he wanted to mention a little point in the matter of the toxemia which resulted from the use of these local anesthetics. Very early in the discussion of the use of cocaine toxic effects were extremely common and all manner of stimulants, such as strychnine, whiskey, and so on were used to counteract the effect. In a case on which he was operating he had had no strychnine or any of those substances present and he used nitroglycerin with the happiest effects and it suddenly dawned on him that nitroglycerin was the physiological antidote of cocaine and of these anesthetic agents. Since then he had not seen any cases of toxic effect from the local anesthetic drugs. He used with the injection a small amount of the nitroglycerin and it physiologically controlled the toxic condition.

Dr. C. F. NASSAU of Philadelphia said that if the surgeon's enthusiasm led him to believe that he could stick in a few syringefuls of a local anesthetic and then go ahead and do his operation, he was going to be bitterly disappointed. The statements to be made to the patient had a great deal to do with the success. There was a certain psychological element that must be judged. One must not operate on every patient under local anesthesia even if he would like to. If one were in the habit of doing it and had in the ward of a hospital a patient who had successfully come through an operation conducted in this way, he had no difficulty in getting the next patient to be done in the same way. A local anesthetic sometimes meant the difference between life and death. He did not believe anybody had any business to give a general anesthetic for strangulated hernias.

Dr. ERNEST LAPLACE of Philadelphia said that he wished to express his conviction that infiltrating anesthesia was a superior mode of anesthesia. In his mind it was superior to lumbar, intravenous or rectal anesthesia, all of which were local methods. In infiltration anesthesia, you could direct, you could inject what you pleased. You knew when you were at the heginning and the end. You did just what you wanted to do.

Dr. S. G. GANT of New York stated that personally he had used eucaine in ⅛ of 1 per cent, solution for the last few years. He used it in all operations. Quinine-urea solution had proven satisfactory. When one did not get anesthesia it was because one did not understand the technique. If we gave an elaborate technique the measure was voted a success. Those who gave local anesthesia would have many patients and increase their reputation.

Dr. KATE BALDWIN of Philadelphia said that she simply wished to add her approval of using local anesthesia for operations more than had been done. She had done almost everything with it. She was very sure that she saw others using general anesthesia where they just as well use the local.

Conservative Treatment of Puerperal Sepsis.—Dr. E.

E. Montgomery of Philadelphia read this paper in which he stated that in his early experience 40 years ago puerperal sepsis was regarded as a specific condition; now it was recognized as being due to the same causes as general surgical sepsis. Then mortality in hospitals was much greater than in private practice and these patients were not admitted to hospitals if it could be avoided. His experience led him to condemn the resort to operative interference in cases of infection as being prejudicial to the patient. It was better to keep the patient clean and trust to nature rather than to interfere surgically. The objection to early surgical interference was that the organs had already passed beyond the reach of surgical measures and these only break down barriers which nature had instituted. He would advocate the use of autogenous vaccines prepared from the blood of the patient, and in cases where these could not be obtained the employment of prepared serums, even horse serum. Measures that should be instituted were those to promote effective elimination and immunity. He would not hesitate to employ surgical measures, even sacrificial surgery, in those cases in which the organs were destroyed and were simply foci for further extension of disease.

Dr. G. E. Shoemaker of Philadelphia said that the word conservative treatment must not be misunderstood as opposed to radical measures, if necessary, but he for one would like to join with those who believed that radical measures as usually understood were not required in the management of puerperal sepsis. He would say at once that his hospital experience was peculiar in this respect. The maternity infections which came were not those which they had themselves delivered. They were, therefore, without a history which was reliable as to the absence of retained pieces of placenta. There were other cases which came as the result of criminal interference and there they had no history. There were other cases which had been hastily examined and recognized and unloaded on the hospital. In these cases one must change his attitude as to noninterference. He must never forget that these cases tended to get well of themselves. In regard to an active interference by a cutting operation, he hesitated to do it above the pubis unless absolutely obliged to do so.

Influence of Lesions of the Rectum on Various Abdominal Conditions.—Dr. Ernest Laplace of Philadelphia read this paper in which he said that abdominal symptoms unaccompanied by any subjective rectal symptoms might be due to a rectal condition whose presence was unsuspected. The lymphatics and venous circulation of the rectum accounted for the ease with which toxins were absorbed and found their way into the general circulation, while the complex innervation of the rectum might account for many reflex symptoms so misleading as not to suggest their possible origin in the rectum. The cardiac, the pyloric, the ileocecal and the anal sphincter being in nervous communication with each other it was no wonder that the irritation of the one might result in reflex spasms of one of the others. His experience impressed him with the necessity of making a thorough examination of the rectum in every abdominal case which came for operation.

Dr. Reed Burns of Scranton said that the fact that cardiospasm could come from an obscure rectal trouble was new to him. He was glad to know it. Whenever one examined a patient for gastrointestinal disturbances he ought to begin at the mouth and end at the anus. There might be pyorrhea, diseased tonsils, or at the bottom of it chronic renal trouble, and gallstone trouble. It might be that the early symptoms of locomotor ataxia were making us think that we had gallstone trouble. So there was no end to it. Microscopical and chemical examination of the contents of the stomach and feces was necessary. A thorough examination of the patient all over was equally necessary and when we had excluded certain things then we figured the diagnosis so that it could be made out.

Closure of Fecal Fistula by Extraperitoneal Method.—Dr. C. F. Nassau of Philadelphia read this paper in which he said that in suppurative or gangrenous conditions of the appendix, two methods of closure were indicated, depending upon whether it was of the large or of the small intestine. For the method described the best condition was when the bowel was adherent to the abdominal wall without interposition of a small coil of intestine. With free exposure of peritoneal cavity, a small drain made hernia possible. Wound infection did not cause a breaking down. The skin scar was excised, cut away and the tract disinfected with phenol and alcohol, the top of the tract closed by sutures, the aponeurosis of the external oblique was cleaned and circular incision made around the tract. The abdominal wall was dissected away close to the fistula. After getting through the edges of the muscular layer, one came upon a layer of transversealis fascia, parietal peritoneum, and peritoneal covering of the bowel. The fistula was amputated, the tract was crushed and tied off close to the bowel wall and the wall of the bowel folded in by row after row of chromic catgut. After the fecal wall was folded out of sight the deepest layer was picked up and a continuous suture of the depth of the wound was made. The internal oblique and transversalis muscles were freed and brought together.

Dr. Ernest Laplace of Philadelphia said that the question Dr. Nassau brought up was most interesting. It was well that he had brought this one point out forcibly. That was the differentiation of these various fistulæ and suggested a method which in itself was bound to be a very successful method, although limited to a very small number of cases.

Habitual Dislocation of the Ulna, Report of a New Operation.—Dr. M. Behrend of Philadelphia read this paper saying that there were two kinds of habitual dislocation of the ulna, traumatic and pathological. Traumatic occur in conjunction with fractures of the radius and ulna. Pathological follow infection usually of the soft parts. His case followed severance of all the flexor tendons at the wrist. Infection followed. After a tedious convalescence it had been found that the ulna remained habitually dislocated. A review of the literature revealed 19 cases reported of habitual dislocation of the pathological variety. This included the writer's case. A new operation was performed which consisted in driving a nail transversely through the ulna and radius. Great care had to be exercised in avoiding the joint. Function was perfect except for a slightly limited supination of the hand. Pronation, flexion, and extension were normal. The patient had returned to his occupation of chauffeur.

The Value of Animal Experimentation.—Dr. Walter B. Cannon of Boston delivered an address on this subject before a general meeting of the Society on Thursday evening, Sept. 21. Dr. Cannon compared the two methods of learning about natural objects, that of observation and that of experimentation under which conditions were controlled, and showed how great had been the increase of our knowledge in physical realms through the application of the experimental method. Precisely similar had been the increase of our knowledge of medical facts through the application of the experimental method to the study of disease. Continuing this idea he showed that a sound basis of acquaintance with tuberculosis came through animal experimentation and that our present effective and hopeful fight against the disease was due directly to this knowledge. The same condition had proved true of bubonic plague; whereas formerly people placed their faith in anti-pestilential pills and royal antidotes, they now trapped the rats whose fleas conveyed the disease. Diphtheria, likewise, had had its mysteries revealed through experimental procedures; and antitoxin, which had very greatly reduced the death rate and suffering from the disease, had not only been discovered through animal experimentation, but was produced through the use of animals. Another disease of similar fearfulness was epidemic cerebrospinal meningitis. Through animal experimentation a method of treatment had been discovered which had reduced the death rate from approximately 75 per cent to about 25 per cent, and greatly lessened the defectiveness of those who survived. The development of surgical asepsis and with it the treatment of childbed fever had likewise been the outcome of experiments on animals. The saving of life from this knowledge alone had been immeasurable. Another way in which animals had been useful to man had been that of serving as means for the discovery of useful drugs, such as the sleep-producing drugs and the local anesthetics. Animals had been directly serviceable in the discovery of salvarsan as a means of treating syphilis. In public health laboratories and in the laboratories of hospitals, animals were used also for diagnosis of obscure diseases. In spite of the enormously valuable benefits which had come to mankind from animal experimentation, there were persons, the antivivisectionists, who had objected to the use of animals for this purpose. The antivivisectionists mainly based their claim on ethical grounds, but when we considered that we permitted the dehorning and branding of cattle, unspeakable barnyard operations, the slaughtering of myriads of birds and beasts for sport—all

without any anesthesia—it seemed ridiculous to select as an object for attack the methods employed in operating on relatively few animals in the laboratories with the hope of reducing pain and suffering in the world. Dr. Cannon then explained that throughout this country regulations had been adopted in all the laboratories where experimental methods were being employed in the study of medicine, which provided for the bodily comfort and the sanitary treatment of the animals, and required all the operations to be sanctioned by the director of the laboratory. Furthermore, that these regulations required all operations likely to cause greater discomfort than anesthetization itself, to be done under anesthesia and to be followed by painless death. The question then was whether in the presence of our ignorance of many diseases, such as measles, scarlet fever and infantile paralysis, we were to bow before the antivivisectionists and do nothing to increase out knowledge of these diseases, or whether we were to make use of the methods which had given us knowledge and consequently greater power in the cure or prevention of the diseases which had been mentioned. The physicians perceiving that more power to fight disease could come only from more knowledge, trust the deeper humanity of the investigators who were seeking that knowledge. In the end society must determine which of these contending parties should prevail.

Philadelphia Neurological Society.

At a stated meeting held October 27, Dr. Alfred Gordon presented "A Case of Astasia-Abasia in a Syphilitic." The patient was a colored man, 46 years old, an insurance agent, who rather suddenly found difficulty in walking, although he could execute all movements with the lower extremities while in bed. The gait was ataxic and station swaying, but the knee-jerks were exaggerated. There were no ocular changes, no sensory disturbances, and no derangement of the sphincters. Examination of the spinal fluid disclosed a strongly positive Wassermann reaction, and the case was looked upon as one of spinal syphilis, involving especially the white substance of the cord. Marked improvement ensued on antisyphilitic treatment.

Dr. George E. Price exhibited "A Case of Paralysis Following Inoculation Against Rabies." The patient was a barber, fifty-three years old, who, while under the influence of alcohol, annoyed a pet dog, by whom he was bitten. The animal was killed without examination of his nervous system, and with a view of averting possible rabies the man was treated with specific virus. As a result there developed paralysis in the lower extremities of progressive character, with exaggerated reflexes and impairment of sensibility, indicative of a lesion of the spinal cord.

Dr. James Hendrie Lloyd exhibited "A Patient with Syringomyelia and Arthropathy of the Shoulder-joint." The patient was a woman, about fifty-eight years old, who presented rigidity of the right shoulder-joint, together with wasting of the intrinsic muscles of the hands and partial *main en griffe*, with preserved tactile sensibility and impaired temperature sense.

Dr. Francis X. Dercum exhibited "A Case of Torsion Neurosis." The patient was a man, about thirty years old, who for a dozen years or more exhibited torsion of the neck and varus of the right foot, without hysterical stigmata.

Dr. Charles W. Burr exhibited "A Boy Presenting Mobile Spasms." The patient was about ten years old, and he at one time presented atonic muscular weakness with flaccidity, and at a later period a tendency to muscular overaction on slight provocation, without actual spasticity. The knee-jerks were increased, the ocular conditions were normal, the electrical reactions were not changed, the mental state was good, and sensibility was preserved.

Dr. William G. Spiller presented a communication entitled "Newer Views Regarding the Pyramidal Tracts, Corroborated by Syringoencephalia."

Ambard's Constant in the Clinic.—Leza concludes that the "constant of Ambard" is the most rational method for exploring the functional capacity of the kidneys. Prostatics are almost always nephritics, which explains the operative non-successes in prostatic subjects. Prostatectomy is advisable when the constant is below 0.07 or between 0.07 and 0.15, but is contraindicated when above 0.15. The constant is of value in the prognosis of nephritis.—*Revista Medica Cubana.*

Books Received.

The Medical Record *is pleased to receive all new publications which may be sent to it, and an acknowledgment will promptly be made of their receipt under this heading; but this is with the distinct understanding that it is under no obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

The Dietetic Treatment of Diabetes. By B. D. Basu, Major, I.M.S. (retired). Published by The Panini Office, Bhuvaneshbari Ashram, Bahadurganj, Allahabad. 1916. Seventh Edition. Revised and enlarged. 105 pages. Price Re. 1-8.

I. K. Therapy in Pulmonary Tuberculosis, with a Summary of Cases and Forty-two Illustrative Charts. By William Barr, M.D., D.Sc., D.P.H. Published by William Wood & Company, New York. 1916. 82 pages. Price, $1.25 net.

Pye's Surgical Handicraft: A Manual of Surgical Manipulations, Minor Surgery, and Other Matters Connected with the Work of House Surgeons and Surgical Dressers. Edited and largerly rewritten by W. H. Clayton-Greene, B.A., M.B., B.S., F.R.C.S. Seventh edition. Fully revised with some additional matter and illustrations. Published by William Wood & Company, New York. 1916. 614 pages. Price, $4.50 net.

A Text-book of Pathology. By W. G. MacCallum, Professor of Pathology in the College of Physicians and Surgeons, Columbia University, New York. Published by W. B. Saunders Company, Philadelphia and London. 1916. Illustrated. Drawings by Alfred Feinberg. 1085 pages. Price, $7.50, cloth.

Facts for Freshmen Concerning the University of Illinois, Intended for Young Men About to Enter College. By Thomas Arkle Clark, Dean of Men, and Arthur Ray Warnock, Assistant Dean of Men. 102 pages. Published by The University. 1916.

Medical and Surgical Reports of the Episcopal Hospital of Philadelphia. Vol. III. 356 pages. Illustrated. Published by Press of Wm. J. Dornan, Philadelphia. 1915.

Traumatic Pneumonia and Traumatic Tuberculosis. By F. Parkes Weber, M.A., M.D., F.R.C.P., London. Published by Adland & Son and West Newman, London. Price, sixpence.

Universal Military Education and Service. The Swiss System for the United States. By Lucien Howe, Fellow of the Royal Society of Medicine; Member of the Royal College of Surgeons; Professor Emeritus of Ophthalmology. Published by G. P. Putnam's Sons, New York and London. The Knickerbocker Press. 1916. 138 pages.

The Healthy Girl. By Mrs. Joseph Cunning, M.B. (Lond.) Hon. Med. Director to the Open-Air School in the London Botanical Gardens and A. Campbell, B.A., Lecturer in Biology and Hygiene, Technical Institution, Swindon. Published by Henry Frowde, and Hodder & Stoughton, London. The Oxford Press, American Branch, New York. 1916. Illustrated. 191 pages. Price, $1.75.

Diseases of Children. By Edwin E. Graham, A.B., M.D., Professor of Diseases of Children in the Jefferson Medical College. Published by Lea & Febiger, Philadelphia and New York. 1916. Illustrated with 89 engravings and 4 plates. 902 pages. Price, $6.00.

A Purin Free Dietary: Sample Menus and Recipes. By Edna Alice Waite and Robert Ellsworth Peck, M.D. Published by Elm City Private Hospital, New Haven, Conn. Paper, 24 pages. Price, 25 cents.

The American Year-Book of Anesthesia and Analgesia. By Various Contributors. F. H. McMechan, A.M., M.D., Editor. Quarto; art buckram; India tint paper; 420 pages and 250 illustrations. Published by Surgery Publishing Company, 92 William St., New York City, 1916. Price, $4.00.

A Practical Treatise on Disorders of the Sexual Function in the Male and Female. By Max Hühner, M.D. Published by F. A. Davis Company, Philadelphia, Pa. 318 Pages. Price, $3.00 net.

Charity Inspector and Social Investigator, Examination Instruction—A Course of Instruction for Candidates for Institutional Inspector, Social Investigator, Inspector State Board of Charities, Charity Application Investigator, etc. By Solomon Heckt, Associate Editor, Civil Service Chronicle, and Julius Hochfelder, LL.M. Published by Civil Service Chronicle, 23 Duane St., New York City. 148 pages. Price, $3.00.

A Text-Book of Human Physiology, Including A Section on Physiologic Apparatus. By Albert P. Brubaker, A.M., M.D. Published by P. Blakiston's Son & Co., 1012 Walnut St., Philadelphia, Pa., Fifth Edition. Revised and Enlarged with 1 Colored Plate and 359 Illustrations. 776 Pages, Price, $3.00 net.

Lippincott's Nursing Manuals—Care and Feeding of Infants and Children, A Text-Book for Trained Nurses. By Walter Reeve Ramsey, M.D., Including Suggestions on Nursing by Margaret B. Lettice and Nann Gossman. Published by J. B. Lippincott Company, Philadelphia & London. 123 Illustrations. 290 Pages. Price, $3.00 net.

The Problems of Physiological and Pathological Chemistry of Metabolism, For Students, Physicians, Biologists and Chemists. By Dr. Otto Fürth, Authorized Translation by Allen J. Smith. Published by J. B. Lippincott Company, Philadelphia & London, 667 Pages. Price, $6.00.

Physiological Chemistry—A Text-Book and Manual for Students. By Albert P. Mathews, Ph.D., Professor of Physiological Chemistry, The University of Chicago. Published by William Wood & Co., New York, 1916. Second edition. Illustrated. 1037 pages. Price, $4.25 net.

A System of Mature Medicine as Taught in McCormick Medical College, Chicago, Ill., founded 1893. chartered in Illinois. By Charles McCormick, M.D. Published by McCormick Medical College, Chicago, Ill. 1916. Vol. I, Optics and Ophthalmology. Illustrated. 319 pages. Price, $20.

Précis-Résumé de Chirugie de Guerre. Par Jean Fiolle, Chirurgien des Hôpitaux, Professeur suppléant à l'Ecole de Médecine de Marseille, Aide-major à l'ambulance chirurgicale automobile 21; et Paul Fiolle, Ancien interne des hôpitaux et de la clinique urologique de Marseille, Aide-major du Ier corps colonial. Préface de M. le Professeur Jacob du Val de Grace. Librairie Félix Alcan, Paris. 148 pages. Price, 2 francs.

Vaccine Therapy in General Practice. Third edition. By G. H. Sherman, M.D. Published by G. H. Sherman, M.D., Detroit, Mich. 1916. 523 pages.

Practical Bacteriology, Blood Work, and Animal Parasitology, including Bacteriological Keys, Zoological Tables, and Explanatory Clinical Notes. By E. R. Stitt, A.B., Ph.G., M.D. Published by P. Blakiston's Son & Co., Philadelphia, Pa. Fourth edition, revised and enlarged with four plates and 115 other illustrations containing 505 figures. 497 pages. Price, $2 net.

Principles of Diagnosis and Treatment in Heart Affections. By Sir James Mackenzie, M.D., F.R.S., F.R.C.P., LL.D. Ab. & Ed., F.R.C.P.I. (Hon.). Published by Henry Frowde & Hodder & Stoughton, London. Oxford University Press, American Branch, New York. 1916. 264 pages. Price, $2.50.

International Clinics, A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles. By Leading Members of the Medical Profession Throughout the World. Edited by H. R. M. Landis, M.D. Vol. III. Twenty-sixth series, 1916. Published by J. B. Lippincott Company. Illustrated. 309 pages. Price, $2.

Syphilis and the Nervous System for Practitioners, Neurologists and Syphilologists. By Dr. Max Nonne, Chief of the Nervous Department in the General Hospital, Hamburg, Eppendorf. Authorized translation from the second revised and enlarged German edition by Charles R. Ball, B.A., M.D. Published by J. B. Lippincott Company, Philadelphia & London. 98 illustrations in Text. Second American edition revised. 450 pages. Price, $4.

Manual of Psychiatry. By J. Rogues de Fursac, M.D., Formerly Chief of Clinic at the Medical Faculty of Paris, Physician in chief of the Public Insane Asylums of the Seine Department, and A. J. Rosanoff, M.D., First Assistant Physician, Kings Park State Hospital, N. Y. Published by John Wiley & Sons, Inc., New York 1916. Fourth edition. Revised and enlarged. 522 pages.

The Rockefeller Foundation International Health Commission. Second Annual Report January 1, 1915—December 31, 1915. Published by the Offices of the Commission, 61 Broadway, New York, N. Y., U. S. A., January, 1916; 185 pages.

Seventeenth Annual Report of the State Board of Insanity of the Commonwealth of Massachusetts, for the Year Ending November 30, 1915. Published by Wright & Potter Printing Co., State Printers, 32 Derne Street, 1916. Public Document No. 63; 383 pages.

Therapeutic Hints.

War Treatment for the Eczemas.—While no new drugs are being used for the treatment of these conditions, it is interesting to note the test the old ones are standing. For moist eczema the following paste should be applied liberally and often. As there is a tendency for this paste to dry in the jar, a small amount of water may be added to it upon application:

℞ Sulphur, 10
Chalk, 10
Oxide of zinc ointment, 80

After the death of the cocci and consequent reduction of inflammation and itching, the application of a simple paste containing 1 per cent. carbolic acid or creosote, or 10 or 12 per cent. tar will be found very efficacious.

For the callous or horny variety of dry eczema, Hebra's lead ointment (unguentum diachylon), with the addition of 10 to 12 per cent. tar, or 2 per cent. salicylic acid, or 1 per cent. carbolic acid, or balsam of Peru may be applied. These drugs relieve the intense itching. Soap and water should be avoided in cases of eczema and a mild oil used to cleanse the parts. In the seborrhoic cases, which occur more often in summer, the chalk-sulphur-zinc paste already given is a specific. The dry papular eczemas may be treated by applying chrysarobin 1, collodion 20, to the affected area with a pledget of cotton wool or sterile gauze, and while it is drying Hebra's ointment may be rubbed in thoroughly with the hand. The application of the ointment upon the collodion removes irritation and spreading of the eczema. The dressing must be repeated when the crust comes off.—*Berliner klinische Wochenschrift.*

General Treatment of Chronic Nephritis.—Boyd follows this régime in these cases: Nitrogen retention must be reduced or eliminated principally through the diet. When the patient is able to stand it, all nourishment must be withdrawn for twenty-four hours and thirst satisfied with distilled water. Purgatives should be administered, as much nitrogenous waste can be carried off through the intestines. Hot air baths or hot packs may also be employed. After this rest period a non-protein diet is begun, consisting of arrowroot cooked with water, cream, sugar, and such stewed fruits that do not contain benzoic acid, such as apples, prunes, and figs. This plan may be continued for one or two weeks without any deleterious effect upon the patient's strength, and may produce a definite fall in blood nitrogen. Milk may now be given and stronger and more palatable farinaceous foods than water-arrowroot added to the diet. This rest treatment answers as well in the early stages of acute nephritis, as it allows complete, or nearly so, rest for the kidneys.—*Edinburgh Medical Journal.*

Sodium Hypochlorite as a Wound Dressing.—This drug possesses a high germicidal action even in the presence of serum, and is harmless also where surgical instruments and cotton materials, both colored and white, are concerned. It is used in the following proportions: Sodium carbonate, 550 gm., is mixed with bleaching powder, 800 gm.; this mixture is dissolved in half a carboy of water, the solution thoroughly shaken and made up to 40 litres, the clear fluid poured off and 150 gm. boric acid added. This is a concentrated form of the solution (4 per cent.); it must be diluted with six parts of water before use, and will keep for a month.—*Brit. Med. Jour. Prescriber.*

THE CRUCIAL AGE OF MAN.*

BY W. STANTON GLEASON, M.D.,

NEWBURGH, N. Y.

THE crucial age of man is practically that period of his existence ranging between the ages of forty-five and fifty-five. It is the age when the majority of active energetic men drop away or are seriously incapacitated by degenerative processes undermining their inherent vitality. Influences of birth, environment, education, etc., all have an effect to advance or lower the dial point of their existence. But from any point of view it is generally recognized that at man's crucial age the death rate is steadily increasing, especially among those who are the mental and physical brawn of professional and mercantile life. Their loss is preeminently a distinct one, for they drop out before their allotted cycle is complete or their work accomplished. Under this consideration as a profession we perforce ask ourselves the question. Is there not more active means whereby we may in a partial sense at least solve this medical problem? We realize that acute disease and so-called accidents of life may cause many fatalities at the crucial age. Then again many frail beings who through modern methods of treatment weathered the stormy conditions of childhood are wrecked on the rocks of middle life, their vitality exhausted and their span of life run out. But it is the average man under average conditions and modern environment who presents himself for our study and aid, and it is for us to carry him through if possible.

Amid the clouds of theory as to the incipient underlying forces that bear heavily upon this period of the active man's existence, basic causes are gradually being evolved which are weathering the test of experiment and we hope for increasing results.

The primary efforts in the solution of this question have been advanced through the effective conjoined work of the clinician and laboratory investigator. And in order to familiarize ourselves with those deductions which have passed beyond the theoretical test, it is well for us first to recapitulate the normal chemical changes and control in the human body. For it is not possible to appreciate the abnormal unless we have an absolute picture of the normal. That there are chemical and nervous causes for physical retrogression at the crucial age is well established, and it is universally recognized that the chemical changes in protoplasm which constitute its metabolism are the basis of all the phenomena of life. Sherrington shows us that all activities of the body, muscular, glandular, somatic, and visceral, are controlled and regulated by the nervous system. Herbst drawing his deductions from experiments upon lower animals, states that at some stage of development the nervous system has an important action upon growth and development. Bayless and Starling proves that an autonomic or self-acting system exists at different points in the human body apart from the central nervous system, and that the plexus of Auerbach, a self-acting point, presides over peristaltic movements of the intestines. Magnus indicates that even the swaying movements in the intestines formerly regarded as purely muscular are dependent upon the plexus of Auerbach. The existence of peripheral plexuses in the walls of blood vessels has been demonstrated by Dogiel, and their presence explains many of the phenomena of local control after nerve section. The further investigation by Langley Anderson and Gaskell indicates with emphasis the important influences of the nervous system upon development, growth and nutrition. Therefore the prime factor in the control of the human body in all its various functions is the nervous system.

The Chemical Aspect.—Under normal chemical conditions it is generally appreciated that the ductless glands and their internal secretions play an important part in sustaining the equilibrium of metabolisms. Paton holds that perfect metabolism of advanced life is governed largely by the internal secretions of the ductless glands. Mental emotions, especially care, grief, etc., powerfully influence the ductless glands with the secondary effect of slow degeneration.

Strauss, Adami and Watson deduced the conclusion that the liver and kidneys are closely allied to the thyroid, and when this gland degenerates the other organs are seriously affected. Eppinger and Falsa divide the ductless or endocrinous glands into two groups according to the action of their internal secretions.

1. The "accelerator" group, including the suprarenals, or adrenals, and the thyroid gland. All three increase protein metabolism. The adrenals cause mobilization of carbohydrates in liver. The thyroid causes increased fat absorption.

2. To the "inhibitory" group belong the pancreas and parathyroids; both retard protein metabolism and restrain sugar mobilization in the liver. According to this grouping and action, increased sugar production depends upon influences that stimulates the accelerator secretion of the suprarenals or lessen the restraining of the pancreatic secretions.

The gonads, or sexual glands, also have an internal secretion which acts upon the metabolism of the body to stimulate it in each sex in a specific manner. It has been shown that the interrelationship

*Read at a meeting of the First District Branch of the Medical Society of the State of New York, at Poughkeepsie, Oct. 14, 1916.

of the internal secretion and the nervous system seems to indicate a dominance of the nervous system over the internal secretion. The question is raised how far the body, mental development, and character of the individual are influenced by the condition of the endocrinous glands. The supposition in the light of present investigation is that the influence is an important one. Any disturbance of this perfectly controlled cycle brings lowered nutrition, diminished metabolism, and incipient degenerative processes.

Toxins.—The agents of unrest in this complete control are the toxins the insidious rust in the normally perfect mechanism. The initial step in toxic disturbances is based on our knowledge of protein digestion. Through the investigations of Kutscher and Abderhalden, and the epoch making split-protein announcement of Vaughan, much of the mist of the past has faded away as regards the ultimate of protein digestion. Vaughan holds that "the body to be in perfect health must have all the cells functionate in harmony, and as these cells are made up of protein to a large extent they must have protein food. The proteins entering the human system through the intestines are split into amino acids and synthesized into specific proteins. The cells of each organ have their own ferments peculiar to that organ and these ferments act to defend the cells against foreign proteins." If, however, the foreign split-proteins overwhelm these ferments the possibility of ultimate cell degeneration is imminent. The toxic products of the anaerobic bacteria of the intestines acting on protein bodies produce as we know, indol, phenol, etc. These compounds experimentally fed to animals bring about changes that are strikingly similar to those pathological processes common to the aged.

Lane has emphasized that in health maintenance the question of prime importance is body drainage, the non-absorption of poisons, and the elimination of whatever poisonous matters may be found in the intestinal canal. It is reasonably well proven by Armstrong and others that toward middle life the proximal end of the large intestine favors only the digestion of vegetable substances and the conditions are especially favorable to decomposition of protein products and the formation of bacterial toxins. The deductions of Fisher and MacFadyen after a series of test meals with subjects at the turn of active life, bring out clearly the fact that if food residues are abundant, intestinal stasis is prolonged, and the antiseptic natural power of the intestinal wall is weakened, then the putrefactive flora reaches its maximum development. Barger and Dale further argue that "we have not isolated all the active principles as products of bacterial action in the intestine, and these poisons have no doubt a powerful influence in disturbing enzyme activity. And as the enzymes are the foundation of cellular activity, any disturbance in their action would lead to abnormal phases of metabolism."

Eastman points out that toxemia from the colon can come from colitis, adhesions, colon dilatations, viscerptosis, and stasis. Bassler, Adami, and others have shown that various forms of anaerobic bacteria are the evident causes in the formation of adhesions.

Lane and his school hold that the human race would be better off without a colon because it is the seat of so much misery. The originality of Lane's idea, and the energy with which he followed his theory excited the admiration of the medical profession. But the vista of health and relief for victims of intestinal stasis and chronic arthritis through ileosigmoidostomy has yet to be more fully verified.

Mr. Arthur Keith of London, according to the *British Journal of Surgery*, believes that neither position of the intestines nor peritoneal bands play an important part in the causation of intestinal stasis, deducing his conclusions from a long list of *x*-ray pictures of Jordan.

Bottomley points out that in all his cases of suspected intestinal stasis the *x*-ray always reported positive, which report was not always demonstrated by operation. It is evident the final swing of the surgical pendulum tends gradually toward conservatism, and it becomes more and more evident that the long suffering colon is less the happy hunting ground surgically for the operative cure of most of man's woes. However, deducting an overenthusiasm in the original Metchnikoff idea, there still remains the broad ground of established fact deduced from unbiased sources and experience that the intestines are the seat of far-reaching insidious poisons, especially evident at the crucial age of man. Through the intestinal and metabolic poisons demonstrated and undemonstrated, which are potently active at the turn of life's activity, we find at least an argumentative cause for disturbance of the nervous systemic control and the foundation laid in metabolic changes for arteriosclerosis, uric acid excess, arthritic complications, and possibly diabetes mellitus.

Arteriosclerosis.—We know that arteriosclerosis is a low grade inflammation of the coats of the arteries, usually with progressive degeneration. We also know that these undermining processes, when they exist, are usually found after the age of forty. How well do we know the causes? The clinician and the laboratory worker urge that arteriosclerosis is probably evolved from a toxic origin, not the accepted toxic effect of syphilis and lead, but toxemias generated in the human body through lowered defense. Wheeler thinks that the usual, but not the only cause of this poisoning is a special animal protein to which the particular body cells have become sensitive. Vaughan also cites instances of this sensitive state being produced in animals by injecting them with the serum of the susceptible individual. If we knew the particular protein which is poisoning our patient, we could apply the "few protein" diet, and in theory at least work out his salvation.

Heredity no doubt is a factor in arteriosclerosis. The legacy of lowered resistance makes for the second generation a special susceptibility for the insidious advances of the gouty or uric-acid diathesis, with the complicating arteriosclerosis. This type seems to be unusually prone to meat-protein poisoning, and it is for them to be well advised as to dieteties. Then again there are types primarily normal in every physical sense, who unguided carve out their own cycle of existence. Their years are punctuated with a history all their own, a history of overindulgence in eating and drinking. They burn more than their quota of midnight oil in satisfying their mental and physical sense. And finally having fulfilled all the elements in the formula for producing arteriosclerosis, with high blood pressure and casts in the urine, they drop out in crossing the crucial bridge. As another example we have the earnest strenuous workers in both business and professional lines, whose brains acting in

close concentration keep the mental and physical forces at extreme high tension. With them the day of rest is ever an advancing point, an anticipated goal, evanescent as the will-o'-the wisp. There is no doubt, especially in this class, that certain poisons are developed probably from intestinal sources which have not yet been identified, which are produced by lowered resistance through high systemic tension. The toxins acting slowly and insidiously gradually undermine the vitality, causing increased blood pressure, cardiovascular changes and finally apoplexy or invalidism.

Uric Acid.—In gout there is always an excess of uric acid in the blood, and the prime lesion of gout is the deposition of uric acid in the form of sodium biurate at the points of least resistance. Although uric acid is always found in excess in the blood in even incipient gout, there is a growing conviction that it plays a secondary part in the symptom complex. Futcher emphasizes this in stating that uric acid is a mere weapon of greater forces comparatively unknown. There is no experimental proof that an excess of uric acid causes special toxic symptoms. The summary of the uric acid argument is that uric acid, or irregular gout, is a disease of intermediary purin metabolism, in which certain tissue ferments play an important role, and some unknown toxic agent or throw down of purin metabolism is the controlling force in the insidious terminal results.

Chronic arthritis may have an indirect affinity with the gouty diathesis; or again chronic arthritis may be acquired from a focal source due to a chronic confined infection or possibly some form of intestinal toxin. An examination of 498 cases of chronic arthritis in the service of Dr. Frank Billings furnished valuable information on the incidence of mouth infections, 76 per cent. of these showed well defined pyorrhea after *x*-ray examination. Focal sources of infection are usually found in the head in the form of alveolar abscess, tonsillar abscess, and various chronic sinus conditions. Billings considers focal infection as largely responsible for arthritis, chronic appendicitis, cholecystitis, pancreatitis, etc. In focal infection extreme difficulty has been experienced by observers in isolating the specific germ or germs. It is not found in the joint cavities, the place usually examined, but it is found in the areolar tissue about the joint. This definite organism has been isolated from the human subject afflicted with rheumatic fever injected into rabbits producing a disease identical with that in man—this has been confirmed by Tuboulet and Wassermann.

Rosenow emphasizes the fact that focal sites of infection furnish a place where bacteria may acquire new properties. These properties are brought about by a mutation or change of bacteria from one type into another type of radically different toxic effect.

Elliott also writes that in the treatment of our patients from focal infections the autogenous vaccines in order to be of any avail must be obtained from closed cavities under proper antiseptic precautions. These cavities are practically human test-tubes, and the streptococci in these concealed cavities under low oxygen pressure and in the presence of other bacteria lose their virulence and acquire a special affinity for joints or the endocardium.

Raines' theory that the organism causing the arthritis may also attack the nervous system is generally accepted. Any break in the normal must be met by prompt action especially at the crucial age when the defenses are weakening.

Diabetes Mellitus.—According to the United States mortality Statistics of 1909, diabetes mellitus is most common after forty, and therefore is a distinct menace to mankind at the vulnerable age. It is the belief of some authors that diabetes is becoming more frequent, the assigned cause being increasing wealth and consequent indulgence. Foster, however, asserts that better evidence is required to establish the fact. No theory has been advanced which explains to us all the insidious influences of this disease; the hypotheses brought forward evidently move us nearer a final solution, but in the meantime the general practitioner awaits the final verdict of the laboratory. Palacios considers diabetes a disturbance of metabolism from intestinal toxins. Allen holds that an amboceptor normally supplied by the pancreas is lacking in the disease state, and in default of amboceptor the cells are unable to fix and utilize the sugar.

Warthim and Wilson very recently showed histological syphilitic changes in six autopsies on diabetics, four showing the *Spirocheta pallida* in the myocardium; they deduce the conclusion that "it is very probable that latent syphilis is the chief factor in the production of this form of pancreatitis most frequently associated with diabetes, but diabetes is not always coincident with severe degrees of pancreatitis." Our present precise methods of treatment of diabetes mellitus are due to the well conceived idea of Dr. Frederick Allen, and through this impetus medicine has made a great stride forward in the management of this disease. Due credit should also be given to Nellis Foster, Joslin, and others, who have sustained this work in the study of human chemistry. Allen's methods are too well known to you for repetition, but I would emphasize that to be distinctly true to his plan, two weeks' initial treatment at least should be given your patient in a hospital, in close proximity to the laboratory. For it is only keen observation of the daily urinary changes and the physical condition of our patient that makes for ultimate success in true diabetes. Consider, however, your diabetic at the crucial age also afflicted with arteriosclerosis, traces of albumin in the urine and casts. This picture presents to you a problem demanding special skill to pilot your patient safely between the frowning rocks of dietetic possibilities. It has been well said that under such a cloud we must treat the man, not the disease, for the latter is incurable. We must rely on the proteins of milk, cream and cheese, and establish an index of tolerance toward certain foods as oatmeal and various starches. In order to keep our patient up to the highest possible point of physical energy, the caloric estimate of daily food consumption must be carefully made. Watch carefully heart and kidney function, being always alert to counterbalance an intensification of symptoms toward either disease.

Summary.—In this general review of real and theoretical data of possible causes of degenerative changes, we appreciate full well that the laboratory worker and clinician only partially answer the question of the possibility of conserving and prolonging life at the crucial age. In the face of this obscurity it behooves us to take the fragments of established fact and weave them into rules and methods and apply them with energy. In estimating the known processes of degeneration at middle life, there is but slight variance of opinion in the deduction that

toxins and acids are the insidious factors in gradually disturbing the balance and control of the human organism. These toxins, known and unknown as far as science has determined, are those generated in the intestines, those generated through faulty metabolism, and also those generated from infective or focal sources. Imbued with this present day enlightenment, we should advise our patients along a broad common-sense line of procedure. Individualize every case, appreciating that ancestry, mode of life, environment, and hygienic conditions are as important in the final estimate as the chemical and physical findings.

A full synopsis of causes bearing upon the integrity of individual welfare must be made with all the mechanical and laboratory aid within our scope. For this type of manhood relegate medicines to an accessible port, for refuge only in case of storm. Treat toxemia largely as a dietetic error, and regulate your individual diet lists accordingly. Food demands must be met by careful caloric estimates. As meat protein is especially susceptible to putrefactive changes in the intestines its use should be strictly limited. Substitute to an extent cheese for meat protein unless cheese indigestion forbids. Use vegetables and greens and the carbohydrates generally with milk and milk products. The use of fruits is largely a matter of individual estimate. If uric acid with gouty conditions prevail, acid fruits are forbidden, and the same argument holds true in a rheumatic diathesis. The use of tobacco and alcoholic beverages should be regulated through careful judgment as to individual temperament. My experience proves that a starvation day at stated intervals enables nature's defenses to reestablish their functions. Daily bowel actions are imperative, and this must be largely brought about with a ratio of coarse-grained food in conjunction with exercise and abdominal massage. Avoid cathartics as far as possible, but if laxatives are required high grade mineral oils hold the preference. A fortnightly dose of castor oil lowers decidedly toxic absorption.

For the extreme nervous tension of business and professional life, exercise in the open air is ideal. But exercise must always be tempered with caution, holding in mind that the rust of age is slightly in evidence. Walking either on the golf field, street, or country road, meets every requirement for relaxation of mind and body. The strong argument, however, leading to prolongation of life, is the consistent and judicious arrangement of periods of rest be it either in hours, days, or months. Nature demands recuperation and the penalty will be paid unless due heed is paid to her demands.

These brief deductions drawn from theory and practical fact, point out to us clearly, that with all our science, Humboldt was about right when he said, "Health is the most admirable manifestation of right living."

Pelvic Lavage.—H. L. Kretschmer and F. W. Gaarde publish their results with the treatment of colon bacillus pyelitis by this procedure. Acute cases are not included. They say that from their results they believe that pelvic lavage gives a greater number of bacteriologic cures in a less space of time than any other form of treatment, but it is important to insure a sterile urine in order to prevent recurrences. The number of injections required varies from one to eight. In several instances they obtained sterile urine after one or two treatments in patients who had been on internal treatment for many months without results. In patients failing to respond to this form of treatment there may be conditions other than simple pyelitis, such as tuberculosis, calculus, or ureteral stricture.—*Journal Am. Med. Association.*

MENTAL HYGIENE.

By HENRY M. FRIEDMAN, M.D., LL.M.,

NEW YORK.

ACTING ASSISTANT SURGEON, UNITED STATES PUBLIC HEALTH SERVICE.

No one can long be in contact with the mentally ill, any more than he can be in contact with the physically ill, without being brought face to face with the questions of causation, of prevention, and, in a lesser degree, of cure. In view of the number of the afflicted, of the universality of their distribution, the physician is in constant touch with them and with the hereditary, social, environmental, as well as medical conditions which must be at their base. He has the opportunity of seeing the cases in embryo as well as when fully developed. Unfortunately, he does not often recognize the relation between early symptoms and fully developed cases. Those especially interested in mental conditions usually see only the fully developed cases—and in the hopeless stages. But for the physician to be able to help in preventive work he must be well orientated on this widely distributed malady. Often, however, even though he sees the causes that operate, and recognizes their significance in the development of these conditions, he is yet unable to prevent their coming into being or to encompass their removal, because the causes are so general, so basic, that they are quite beyond the individual to influence. Yet, unless he is well informed, he cannot be in position to urge on the public the necessary remedial measures. The physician can arouse the public to demand the protection of the mental health of the public, to promote the study of diseases of the mind, and to ameliorate the condition of the afflicted. These are, in a broad way, the elements of mental hygiene.

Mental hygiene is a medical problem, not a lay one, except possibly in the field work. Even there the medical man is of infinitely more value. The nature of mental conditions is not nearly so mysterious as the nature of many physical conditions. It is perhaps not too radical to say that mental conditions are as easily diagnosed as the physical, and that the first steps in evolving therapeutic, but especially prophylactic measures, have long since passed. General knowledge can be further encouraged by opening the psychopathic wards to the profession, by lectures, and by clinics. The idea that insanity and other mental conditions are, so to say, ultra-pathological, and not possible of comprehension or of attack except by the specially qualified or "anointed" specialist, must be cleared away here, as elsewhere, before much progress can be made in the movement for mental hygiene. They are as amenable to the ordinary medical mind as other pathological conditions. They are neither vague nor mysterious.

In speaking of mental hygiene, it is hard for many to conceive of the applicability of so definite a term as hygiene to the heretofore vague and nebulous conceptions of the mind. We usually think of hygiene in terms of the bath, the antiseptic, sewage, food, and the like. Yet whether metaphorically or actually, these factors all have their analogues with respect to the mind. Mental hygiene is, in fact, the basis of all hygiene, since right thinking includes the observance of all hygienic considerations and of all health regulations. At any rate, whether figuratively or not, there are certain

definite matters the institution of which, or the correction of others, lend themselves to the conservation of the mind. The field is wide and varied. It embraces hygienic breeding, actual hygiene of the body, prevention of disease and correction of defects, moderation in the use of food, drugs, and alcohol, abstenance from excesses of all kinds, general improvement of social conditions, proper mental, physical, and vocational training. It also embraces the segregation of the mentally defective and the mentally disordered in proper institutions or hospitals for observation, diagnosis, and treatment, so that they may not be in position to exert a deleterious influence on others. It includes, further, the teaching of right and proper methods of thinking, the training of even temperaments, the encouragement of healthful interests, proper introspection, and the discouragement of improper, artificial, or masturbatory mental habits. Neither school training alone nor home training alone is sufficient to carry out this aim; but both must work in intelligent co-operation.

Heredity plays an important part in mental states but usually only as the foundation for a superimposed abnormal structure built thereon by adverse conditions. There would otherwise be a foundation but no structure. Indeed, it is the aim of mental hygiene to prevent the building of such a structure over an hereditarily defective foundation. On the other hand, many of the mental conditions are not entirely preventable because they seem to be handed down as such from ancestor to progeny, as is so well illustrated in the profound mental deficiencies. There are less profound conditions which are handed down as weakened or inferior constitutions, which, however, requires some environmental adversity to activate. In the matter of prevention, or of hygiene, the only thing that can be done with them is early apprehension and segregation so that they may not come in contact with adverse conditions, and especially so that these stocks may be prevented from passing their defective strains to others. The epileptic, the feebleminded, and the insane are really subjects of notifiable disease conditions. There is as much contagion in them as in infectious diseases—either through improper example or the development or propagation of inferior strains. The clearing-house idea and compulsory central notification of all cases will do much to eradicate them. There are too many illustrations of the hereditary factor in respect to the central nervous system to warrant overlooking or underestimating it in the slightest degree.

The best method of keeping down the defective population has not yet been determined. Marriage laws are unsatisfactory because of the very nature of laws which are capable of combat, varied interpretation and nullification because of the reading into the law of so many exceptions. Although the requirement of health certificates, based on examination before marriage, is a step in the right direction, practically, it has not been found to work out satisfactorily because of the ease with which, for example, syphilitic reactions can be masked, or the difficulty of recognizing incipient conditions, and the injustice of refusing permission to marry to those of defective stock, although they may be greater factors in the transmission of this strain than even those with acquired disease conditions. From 50 to 70 per centum of the mental cases are hereditary. Defectives seem to be especially prolific, probably because they are really lower forms of beings. For institution defectives, criminals, etc., sterilization would seem to be the method of election to destroy the strain. There is, however, a great deal of opposition to this procedure because it is considered cruel, a deprivation of the human right of procreation, and on the ground that the laws of heredity are not yet clear enough on which to found so radical a departure. The study of the laws of heredity promises to be one of the most fruitful fields of human endeavor. At any rate, it is even now obvious that the mental hygiene of the individual must be enforced in the ancestor to be of value to the offspring.

Perhaps one of the largest contributions to the defective element of this country comes through immigration. This is quite natural, for immigration no longer demands the facing of hardships such as was encountered in pioneer days. On the contrary, it is often the path of least resistance for those who are unable to make a place for themselves among their own. Not only is there the likelihood of mass admixtures of defective individuals or of defective stocks but of whole atavistic or aboriginal races. Unless this source is strictly censored, not only with relation to the actual defectives but with relation to the potentially defective or constitutionally inferior, the more domestic or local measures will be continually bowled over by the influx of great numbers of these sources of contamination. Even the keeping out of such stocks *en masse* is not too radical a measure to prevent contamination. The prevention of the marriage of defectives, or other means of inhibiting their further propagation, the exclusion of alien foci of "infection' are hygienic measures of supreme importance.

While the hereditary cases may be considered in the light of damage already done and in so far irremediable, the great mass of acquired disease, which is causative of much of the mental disease incidence, and against which mental hygiene must be especially aimed, is almost entirely preventable. These acquired genetic factors include syphilis, alcoholism, tuberculosis, arterial degeneration, etc. Alcohol alone causes about 20 per centum of the insanities, while the so-called parasyphilitic nervous and mental diseases are almost entirely, if not entirely, syphilitic in origin. Even the many apparently innocent neuroses are of immediate luetic origin or are more indirectly the last shoots of a luetic ancestry. With alcohol may be included the excessive use of drugs. The increase of that part of the incidence of insanity caused by the increased consumption of alcohol and drugs, and against which the campaign for mental hygiene is especially directed, is made clear when one considers that in the last 20 years there has been an increase of 750 per centum in the use of drugs with an expenditure of over 150 million dollars per annum. Even if toxic, somatic, or other pathological conditions are not directly causative they are at least provocative. They are still, without doubt, intangible psychogenic bases combined with the acquired—both must be read together, too much importance placed on neither.

Among acquired conditions predisposing to, or causing insanity, and in the nature of intoxications, are the various infectious diseases, parasitic diseases, nutritional diseases, and internal gland diseases. There is a biochemical relation between mind and body; their greatest forces for good must

go together. Before attempting either to prevent or to treat mental conditions the physical condition must be inquired into. The part played by the hormones, the secretions of the ductless glands, in the causation of mental deficiency and mental disturbances has recently gained much prominence. It is a mooted question whether or not in mental conditions, where hereditary and somatic factors are not evident, the cause cannot be found in the internal secretions, as is illustrated in the mental states in thyroid disease, acromegaly, Addison's disease, etc. The prevention of all these must be left to preventive medicine. Their eradication will in so much reduce the field of the psychiatrist or of the mental hygienist.

Generally poor environmental and unhygienic conditions resulting from congestion, poverty, and ignorance are not, however, individually preventible factors. The hygienist must call the attention of the public to the significance of these conditions in the perpetuation of mental conditions and in arousing the public conscience to the improvement of general and social conditions. The movement of mental hygiene is broad enough to call for a social organization to combat this malady. Social medicine has now a definite place in the medical sciences. The improvement of conditions among the sick as well as among the well is quite within the sphere of social medicine. It already has an established place in many large medical institutions—with follow-up work, help, and advice subsequent to hospital or clinic treatment. This sort of work is even more necessary in psychopathic conditions. Pernicious social influences often activate the constitutionally inferior. For these a desirable environment must be created to keep them from changing from latent to active. Adverse environment acts badly on an already prepared mind—a mind prepared by heredity, by acquired disease, by vices, or by excesses.

Overspeed, highpressure, and overwork in the strenuous life of modern times are large contributors toward mental and physical degeneration. There is a tendency to overspeed for long periods without much rest, which soon breaks the worker down—a tendency to product-efficiency without individual physical efficiency. There seems to be, moreover, also an individual desire to work for a short period of life, at great speed, to acquire sufficient money to live a life of prolonged ease thereafter. It so often culminates, however, in mental and physical breakdown, and is, altogether, very poor economy. Likewise, speedy maturity, forced by improper methods of education, especially in the precocious, encourages early decline, decay, and mental deterioration. In these endeavors we take a great deal of stimulation of all kinds—with dire results to the nervous system. Such stimulants as alcohol, drugs, and pernicious sexual habits all help to hasten one to this end. Alcohol, syphilis, and speed are a trinity that causes much insanity.

Moreover, there are many congenital and acquired physical and sensory conditions which either retard mental development or irritate the nervous system and cause respectively deficiency or disorder. The correction of eye, ear, and nervous conditions is often preventive and curative of some very profound mental states. The correction of defects in early life goes a long way to prevent the development of disorder and disease especially in those with poor constitutions.

Of prime importance in all hygiene, as well in mental hygiene, and in the correction of ills, maldevelopments, etc., is physical training. Logically, physical training is the first step in mental training. A mind devoting itself to physical hygiene is devoting itself at the same time to mental hygiene. *Mems sana in corpore sano* is more true than ever before. Physical training, unlike education, must be begun early. It must be maintained throughout life. It is a habit that does away with many of the postural and sedentary ills of life. It supplies the strength and endurance needed in so many occupations and from which the weak are barred. Physical weakness causes economic weakness, disturbances, and poverty—all inevitable forerunners of disease and disorder.

Sedentary persons have whole systems of unused muscles, and in them corresponding brain areas are rendered useless. It is to this class that the neuropaths especially belong. Motor energy stored up by proper muscular energy can be used or converted into mental energy. The one is really reserve force for the other. The development of one goes hand in hand with the other. Neither can very well get along without the other. Muscular coordination and muscular action are the first things taught the mentally defective. It is through muscular activity that it is hoped to arouse the neighboring and bordering mental centers. Physical training must be selective—to bring out retarded muscle groups. The same physical education cannot be given to every person. In physical as well as in mental training each individual is a case by himself. Muscular development and physical training develop useful central activities, purposeful action, and do not encourage aimless, tiresome, fatiguing, and exhaustive activities. The strongest mind is the one with the least peripheral—useless—activity. It is the one in which most of the unused energy can be converted into mental energy, or used elsewhere in an emergency.

Mental training, while it includes, does not mean entirely educative training. In the last analysis, education is really only a training of the memory—to be sure, the most important faculty. Education lays up information that can be drawn from when needed. But perhaps more important than training the memory and laying up information, at least in the interest of mental stability, is the training of the disposition, the temperament, the general character, of proper methods of thinking, of control of the passions, of introspection, of an understanding of the proper proportion of things, of altruistic and of sympathetic traits, of rapid decision, etc. Indecision is the result of improper training. It is almost worse than too hasty and too superficial decision. Whether by religious methods or otherwise the cultivation of an altruistic sense is a help in maintaining mental equilibrium. Individual faculties which are found retarded must receive special training. It is only in this way that failures and disappointments can be prevented. These are themselves very severe mental traumata, conducive to the development of morbid mental states.

Insanity is rarely of sudden onset; it is the result usually of long standing and continued abuse of the mind, of the body, or of both. Besides, there are premonitory symptoms, often subtle, more often well marked. They may manifest themselves in changes of temperament, of disposition, of character, etc. Personal characteristics are usually very much an organic part of an individual and, normal-

ly, do not undergo sudden changes. It is difficult enough to train them purposely, and then only, if at all, after constant and studied effort. A change in personal character is always significant. Fortunately, in most individuals such a change does not go beyond this stage and does not degenerate into a definite psychosis, especially if there has been early mental training, or if the abuse of the mind has not been too severe. On the other hand, if the significance of the mere change is not recognized and the abuse, overspeed, or excitement, continues, the change turns into a distinct abnormality. And it is thus far the sad experience that when once the boundary lines of change have been overstepped return to the normal is not usual. It may be that the environment that provoked the original condition is still operating and keeps the patient under, or especially because facilities for early individual treatment are not yet afforded; besides, favorable environment is not an element easy to procure. Cures are not nearly such hopeful outcomes as prophylactic measures. Many of the cures are not really cures of the insane but of the pre-insane; and it is in these pre-insane especially that the greatest good can come from mental hygiene, and from voluntary admission into psychopathic hospitals.

Mental hygiene is as broad and comprehensive as preventive medicine, perhaps broader; it is too comprehensive to be definite. The prevention of every abuse comes within its folds. Mental stress and lack of adequate rest from fatigue are two cardinal causes of insanity. They may be classed among the toxic causes because the accumulation of the fatigue products acts as an organic poison. High pressure requirements can in a measure be overcome by periodic rests, changes, or vacations. Change is particularly a great regenerator and rejuvenator. Change of scene and recreation will very often anticipate a mental breakdown. Even the change of scene given in an asylum or hospital is of such benefit; and it is for this reason that it is now universally advocated that persons threatened with mental disturbances apply for voluntary admission to a psychopathic hospital long before the actual break has taken place.

While heretofore the operation of prophylactic measures did not seem as plain where the mind was concerned as in the more tangible somatic conditions, thanks to the mental hygiene movement it is becoming more apparent each day. The development and the conservation of the mental faculties are as important to mental health as the development of the muscles to bodily health. An empty and untrained mind is not a healthy mind. Atrophy is not health. Work and exercise are as necessary to mind as to body—but not overwork. The attempt to educate a nervous or feeble mind under the same conditions of speed and pressure as the normal child is as bad as requiring all children, no matter what their muscular capacity, to undergo the same amount and the same kind of physical training. Exhaustion must follow in both instances. The separation of children into appropriate groups for education and for physical development is a measure of highest prophylactic and hygienic importance. The school competitive system is not desirable for the rapidly growing child. It is perhaps that from the realization of this factor that the various new methods of individual teaching for children have sprung up. The competitive system is the cause of a great deal of menstrual retardation, hysterical manifestations, and psychopathic symptoms in girls about the period of puberty. An average minimum need for a school class should be the only one established and maintained. Native ability will come out in due time without competitive stimulation. Competition is best left for later life, and there is already too much of it even there.

Academic education for those who have ability or inclination only for vocational work causes many failures and disappointments, and acts as a direct injury to the nervous system which is so often permanent. It is highly fatiguing to these motor-minded individuals and its continuance is unhygienic. The teacher should be able to recognize mental fatigue and to provide against it. Fatigue, rest, habit, etc., are elements in the child with which the teacher should be conversant. The teacher can carry out her part in the movement for mental hygiene by being familiar with the physiological and psychological needs of her pupil. Fatigue is often a matter of bad training. It is just as necessary to build up a mental reserve force as it is a physical reserve force, for use in emergencies. Without proper drill aimed at individual needs, capabilities, and possibilities the school becomes merely a forcing or cramming medium. School inspection and child surveys are the means of bringing to light the defective, and the nature of their deficiencies. Coupled with investigation, entire defective family strains can be detected. Proper follow-up work with the defective families can do much to reduce "return" or new cases, as it has done in such diseases as tuberculosis.

Mental retardation and mental defect are not, however, synonymous. Retardation is due to disuse and to neglect; defect is due to inherent brain defect. The apparent results may, however, be the same if care is not taken to differentiate them. Every mental faculty, memory, attention, will, etc., may be retarded through neglect in training and through disuse. The lack of discipline of home or of school permits the mind to lag and allows outside pernicious influences the easier to take hold. Lack of interest follows lack of understanding. It is the discipline of effort, of work, of interest, that trains the mental faculties into habits of work and habits of right thinking. It takes the mind away from the many pernicious extrinsic psychological processes, so conducive to mental disturbances. In the better classes especially are nervous disorders the result of idleness, sedentary life, and a lack of proper mental interests. The ordinary forms of amusement are no longer satisfying to them, and excesses of various kinds are the natural results. They become blasé, introspective, self-centered, they suffer from functional nervous disorders, and then, lastly, actual psychoses. An unproductive life, no matter in what sphere of society, as well as all forms of overstimulation are factors in the development of mental disturbances. Mental and physical activity are hygienic and therapeutic measures, when properly selected and not overdone.

Mental training must include a training of self-reliance, else there will ensue a sort of negativism, indecision, apathy, and lack of mental energy. While these may be due to fatigue they are more often due to neglect. The acquirement of desirable mental habits is, likewise, a matter of training. Distinct effort will cure the tendency to trivial anxieties and worries. Perhaps encouragement to unburden themselves of their worries and anxieties

immediately as they occur to some one who is sympathetic, perhaps to counsellors and confessors, will be helpful. This may be the human origin of the confessional—and the calm and ease it affords those who can take advantage of it justifies its use.

Habits of exaggerating, of looking for slight personal affronts to brood over must be discouraged during the developmental period. The tendency can in a measure be overcome by teaching a philosophic analysis of things—a better understanding of real proportions in life. A relentless hunt for the good in the bad—for the sunny side of life, is a great help in overcoming such baneful mental habits as suspiciousness, supersensitiveness, seclusiveness, anxiety, fear, despondency, undue excitement, idleness, day dreaming, and the like.

The neuropathic, nervous children must be exposed to some adversity—to the elements, so to say—and not coddled too much; they must be encouraged to learn their own legs; they must be "hardened." Children who rarely display any emotion, and are of the "shut-in" type, must even be goaded to the display of emotion, almost by any method, in order that they may have an opportunity to indulge in the "gymnastics of emotion." Environment has a great deal to do with the development of desirable mental habits, and unless the desirable ones are knowingly developed and the undesirable ones knowingly eradicated the mind will founder with the first ill wind. Favorable external influences such as are furnished by settlements, recreation and community centers are hygienic measures social in nature and of very first importance. It is with this sort of therapeutics and prophylaxis that social medicine is concerned. For the very weakest mentally, occupations must be furnished that keep the mind pleasurably occupied, so that they may have no time to exercise their morbid mental habits. Perhaps the acquirements of hobbies is a valuable preventive measure.

Intense emotion is just as fatiguing as mental or motor effort. In early life, at least, and in the neuropathic, it must be studiously avoided. Those who are temperamentally thus inclined should be urged to keep away from displays, exhibitions, or anything which they know from experience has a tendency to arouse intense emotion—at least until they have trained themselves against it. To be of value to the organism emotion must be followed by action; much emotion should not be allowed to accumulate without some commensurate action. Distinct vital energies, without any adequate return, are consumed by such displays of emotion as anger, jealousy, etc. The telling of fear stories to children arouses emotion which often remains as a distinct psychic injury. For the same reason children should never be led into experiences that do not perfectly belong to their years.

Thus far the treatment of mental conditions has been almost entirely custodial. There were maintained asylums or retreats from which few returned. Yet even with the mere improvement of the custodial care given these patients the number of cures have increased. Further improvement with respect to facilities, space, etc., coupled with a rational search for the genetic factors will return many more to society. For incipient cases, for the so-called psychoneurosis, psychasthenias, voluntary admission to hospitals are recognized to be prominent factors in prophylaxis. Even mere residence in a hospital is of benefit because it takes these patients away from the noise and turmoil of life, from which they are really suffering and from which they seek to escape and submerge in the form of their delusions. The opportunity given for observation, diagnosis, and the correction of somatic difficulties must prove helpful. If indicated, psychoanalytic treatment can be given under the very best conditions. Hospital care can be combined with rest, work, exercise, and occupation.

On the other hand, definite therapeutic measures in the treatment of the insane has practically not yet been developed, except in the more recent methods of psychoanalysis. It is plain that the mentally ill must be taught to find themselves. And whatever may be said in criticism of the methods, principles, or possibilities of psychoanalysis this has been the means of opening the field of active treatment in cases heretofore closed to any but passive measures. Time and study will reveal how much actual merit there is in the method. It is intended by this to teach patients to find themselves by having them abandon their own aimless introspection and substituting instead a more methodical and rational introspection—an analytical and not a pathological introspection. Eventually, psychoanalysis must have its place taken by a sort of autopsychoanalysis—if the benefits are to be very broad. Rational psychoanalysis contemplates teaching the patient to become a "more rational, thoughtful, and mature individual." Here lies its place in mental hygiene. Psychoanalysis searches for the truth behind any impression, in order that the impression may not soar into the mysterious, beyond control, where it becomes a fascination from which it is hard to withdraw; not to allow impressions to become exaggerated, not to allow them to grow needlessly, but to analyze, interpret and separate all thoughts that obsess the patient into their component or genetic factors. In order to be in a position at any time to offer mental aid to a patient it is necessary to make complete analyses of the personality with respect to traits, habits, work, etc., so that any breach may be found and filled in. In all forms of mental treatment or of mental work a degree of intimacy, sympathy, and confidence must be maintained, much beyond that required in ordinary medical work.

Ordinary psychological investigations deal with motor, sensory, and purely intellectual elements; but these are difficult to interpret in terms of their dynamic relation to the personality of the individual—which is disordered in the insane. These latter may be called the intrinsic psychologic elements as against the former or extrinsic which deal with the external dynamic manifestations of the mind. It is with the intrinsic elements that psychotherapeutics is concerned. Therapeutic measures attempt to create order out of disorder, comprehension out of misapprehension—to clear away the psychic débris whose presence lends to unhygienic conditions in the mind.

One is said to be well balanced mentally who is able to hold and does hold a proper relation to his environment; he is unbalanced when in a dynamic sense he is disturbed by such psychogenic factors as conflicts, tangles, day dreams, etc. There is, then, no sharp line of demarcation between sanity and insanity. It is the ability to adjust or to readjust oneself under adversity which determines sanity or insanity. To cure means to help to readjust. Mental hygiene may mean a general readjustment of environment to the many of a class against

mere individual adjustment. During the period of maladjustment, there are manifestations of temper, fads, fancies, seclusiveness, etc. Normal persons may have these same symptoms after stress, but they are the normal ones because they are able to overcome them, and to readjust themselves, while the abnormal cannot—at least not without help.

In the body, fever, pain, and other reactions are Nature's efforts at protection; in the mind, such manifestations as delusions, illusions, etc., are efforts of the mind at readjustment, or attempts in this way to get away from sources of irritation. These are attempts to become readjusted to an environment of difficulty. There is an attempt to reestablish an equilibrium. We usually see only those who fail in these attempts. Those who have succeeded do not come under observation. As in other conditions a great many get well without observation, and, of course, without treatment. More of this type can get well, or, better, can avoid becoming ill, by conforming to general and mental hygienic measures. In respect to the mind, then, we are concerned mainly with the failures at readjustment, but we must also make it easier for the successful to determine a successful issue.

On the other hand, psychoanalysis has its limitations. By its very nature it is a therapeutic measure of refinement in language taking place between patient and physician. The best results can occur only in those who by nature or through education have acquired sufficient refinement of language so that many of the subtle variations of expressing mental processes can be conveyed to them. To the crude, whose range of language is restricted to the lower degrees of expressions—expressions even much lower than the sum of their very few experiences—in whom there is not even language for the grossest of their experiences, analysis cannot be made. Besides, of course, it cannot be applied to the excited or to the deeply depressed. It is limited in its action to the pre-insane, as a prophylactic measure, and is in no wise a panacea for all mental ills. Psychoanalysis is a therapeutic measure rich in language, in terms, and in expressions. The experiences of the ignorant are more often bodily than psychic. The range within which there can be injury of their minds is very small. A wealth of psychic experiences and actions in a constitutionally inferior mind are the most prolific causes of mental injuries.

Undue repression of desires, emotions, and sentiments are psychogenic factors, and while normally a certain amount of repression is necessary for social order, the weak can stand little of it, and perhaps even the strong not too much of it without harm. Society demands a certain amount of repression. It is the cognizance of the need for this demand and the ability to live up to it that makes for the normal. The tendency in the young to undue repression, dissociation of the personality into the unreal and the imaginative, to indulgence in emotional excesses and the like must be overcome by substituting appropriate action and healthful recreation. A little self-scrutiny does no harm, if it becomes the means of knowing onself, and provided it does not degenerate into too great an introspection; psychoanalysis is the giving of therapeutic introspection. The insane complex, in which there is a submersion out of harm's way, is a medium of protection. Psychotherapeutics must discover the conditions from which the patient finds himself forced to escape, and the removal of these conditions is the goal of treatment. Many of us normal beings submerge into minor depressions, the blues, self-pity, self-engrossment, fantasy, etc., in order to escape some unhappy or unpleasant condition; we are normal, however, according to our ability to rise again and stay on the surface. The abnormal cannot, at least not without help, and even then some not at all, because they have sunk for the third and last time, so to say. Perhaps the ability to supply them with a more fruitful, different, or less harmful medium in which to submerge would not be so fatal.

The elements in mental hygiene are, then, the eradication of the hereditary element by restricting propagation by known defectives, by eliminating the disease, the drug, the alcoholic and the excess factor in acquired mental conditions, by the exclusion of alien foci of "infection," by the improvement of general hygienic and social conditions, by proper physical, mental, and vocational training, by voluntary admission of the pre-insane into psychopathic hospitals and the subsequent follow-up work, by psychotherapeutics wherever possible, and lastly by a better understanding by the profession at large of the various phases of mental disorders and their early recognition.

351 East Fiftieth Street.

THE TREATMENT OF MERCURIAL STOMATITIS.*

By Douglass W. Montgomery, M.D.,

San Francisco, Cal.

Some years ago, in conversing with a friend on the effect salvarsan would have on the treatment of syphilis, he remarked that it would certainly make us more strenuous in our employment of mercury. That we have become more exact in our dosage, and more methodical and more energetic in the administration of mercury is most true. Possibly the reasons for this change are not so much the introduction of salvarsan, however, as the discovery of the spirochete and of the Wassermann reaction. The first gives definiteness to our therapeutic thought, and the second impels us to secure a negative result. In the endeavor to obtain a negative result, however, we run the risk of causing inconvenient or distressing symptoms from the drug itself, and in giving mercury prolongedly, as must be done in syphilis, one of the chief incidental accidents is stomatitis.

Mercurial stomatitis is caused by the mercury administered, but in many of its manifestations is far from being directly due to it. The state of the mouth and very especially the sanitary condition of the teeth are of great importance in rendering the patient susceptible to mercury. The mere presence of the teeth is important, as shown by the infrequency of stomatitis in infancy and in toothless old age.

The Normal Mucous Membrane of the Mouth.—The mucous membrane of the mouth should be pink and smooth, and the normal gums should be firm and should hug the teeth tightly. The interdental pyramids of the gums should not be prominent but should sit in between the teeth, so closing the space around the neck. No matter how close the apposition may be, it nevertheless constitutes a weak joint receptive to bacterial attack. An ideally perfect mouth is, however, seldom seen except in infancy.

*Read before the Sonoma County Medical Society, June 8, 1916.

The modern civilized man always has a gastro-enteritis, the condition of which is reflected in his oral cavity. In many people with a dirty mouth, a coated tongue, and a foul alimentary canal, the gums become spongy and redundant and fall away from the teeth, leaving a more or less deep open groove between the gum and the tooth, and besides this the gum pyramids elongate and tend to flap outwards, leaving still larger pockets between the teeth. Food is forced into these grooves and pockets, and when the particles are protein they are attacked by the anaerobic putrefactive bacteria, the deleterious influence of which in combination with mercury, will be taken up later.

The formation about the teeth of phosphate of lime deposits, commonly called tartar, also throws the gums away from their natural close apposition to the teeth. After these inflammatory changes have lasted sometime the gums shrink, exposing the teeth still further to deleterious influences. Although these conditions are not normal, yet their presence in a more or less marked degree is so usual as not to excite comment.

Effect of Mercury on the Mouth and Alimentary Canal.—Mercury, no matter how given, excites the alimentary canal throughout, and the larger the dose the greater the effect. It causes redness and tenderness of the mucous membrane of the mouth, swelling of the gums and of the tongue, a disagreeable metallic taste, a characteristic nauseating fetor of the breath and salivation. The teeth become sensitive in chewing, or when smartly clamped together, or to acids or to heat, and especially to cold, such as ice water, and they get a curious feeling of being too long; in some cases they may loosen and even fall out.

In considering the condition of the mouth the state of the rest of the alimentary canal is of interest, as any disturbance along it reflects itself in the mouth. There may be redness and soreness of the throat, with an abundant accumulation of frothy mucus, such as is so graphically described by Rabelais.[1] Mercury may also cause icterus, vomiting of glairy mucus, and painful diarrhea with watery, mucous stools stained with blood, simulating dysentery.

The local trouble may give rise to severe neuralgia of the fifth nerve. I well remember one of those stubborn, elderly men with fixed habits of thought, who consulted me on account of what he insisted was a neuralgia due to syphilis. I found that besides the neuralgia, he had tender, swollen gums, a wet mouth, and the familiar fetor, and he had been receiving mercurial injections. The pain was so intense that he felt overwhelmed by it, and was bent on having me give him more mercury, although evidently he already had had too much. With the utmost difficulty I persuaded him to defer the mercurial treatment.

Mercury, therefore, when given to a man with a normal mouth may, through its own physiological action, cause highly disagreeable symptoms of a congestive nature, and when the oral cavity is illy kept and irritable, mercury is especially adapted to add seriously to his troubles.

The Interaction Between the Putrefactive Bacteria and Mercury.—Almkvist has worked out this subject in a most fascinating way.[2] As before mentioned, when the proteid foods are pressed into the pockets about the teeth, or into the recesses of the mouth, they are attacked by the anaerobic putrefactive bacteria, principally the fusiform bacillus of Plaut-Vincent and the *Spirochæta dentium*. Among other iniquities perpetrated, these bacteria form H_2S gas.

When mercury is given, either by the mouth, by inunctions, or subcutaneously, it is principally taken up by the blood, and so circulates in the capillary loops of the papillæ of the mucous membrane of the mouth. Here it comes in contact in the capillary wall with the above-mentioned sulphureted hydrogen produced by the putrefactive bacteria, causing a precipitate in these capillary walls of the black sulphide of mercury. This black sulphide, Hg_2S, although usually estimated as being insoluble, is only relatively so, as it exerts a detrimental action upon the capillary loops, and interferes with the function of the vessels in transmitting nourishment, which in its turn, brings about degeneration and molecular death of the superimposed epithelium. This affected epithelium constitutes, therefore, additional dead proteid matter, furnishing still more nutriment to the anaerobic putrefactive bacteria, and so on progressively leading to erosions and to ulcerations of greater or less extent and depth, abscess formation, periostitis, necrosis, for instance of the lower jaw, and even the death of the patient.

Further investigations may either substantiate or invalidate Almkvist's views of the sequence of events constituted by the anaerobic bacteria, H_2S, Hg_2S, and lesion of the capillary walls, but it is unlikely that anything will be found to diminish the etiological importance of the anaerobic bacteria themselves as a cause of inflammation and ulceration in mercurial stomatitis. The weighty influence of this knowledge in our estimation of this condition will be appreciated when treatment is considered.

Sensibility of Certain Locations in the Mouth.—The gums just behind the lower last molars have long been recognized as being particularly sensitive. This seems partly due to the narrow angle between the tooth and the ascending ramus of the lower jaw. If the gum here becomes swollen it is apt to be crowded and irritated in the angle. This irritation is increased if the treatment falls at a time when the wisdom tooth is breaking through the gum, which is not such an unusual coincidence, as I have two such cases in the office at present. Because of the remoteness of this position also, it is difficult to reach it with a tooth-brush, and therefore food frequently lodges, ferments, and irritates. The mucous membrane in this situation often rises into a tender, easily bleeding point, which Almkvist says is nothing more than an interdental pyramid. The gums behind the upper front teeth are also, in my experience, often sensitive, which may be also partly due to the difficulty of getting a tooth brush into this region, and the consequent accumulation of tartar. In a patient under treatment now, this is the only situation that is sensitive, but the sensitiveness in him is not near the teeth, but a little farther back on the riffles.

Almkvist says that he finds the gums behind the upper last molars to be as sensitive as those behind the lower last molars. He ascribes the sensitiveness to the existence of a natural pocket, called the pterygo-gingival angle. There is a fold of the mucosa that extends downwards and outwards from the palate to the gum, called the pterygo-gingival fold. The above-mentioned pocket lies between this fold, the tooth and the cheek, and is therefore called the pterygogingival angle. It is my impression,

however, that the gums about the lower molars give more trouble than those about the upper ones.

The cavities of a carious tooth may also form a focus for troubles, which cause irritation and infection of its gum. A woman at present taking inunctions under my charge has had this trouble adjoining a cavity in which the filling is broken. A portion of the edge of a soft tongue projecting into such a cavity may also become infected. Almkvist gives a striking instance of this.

As before mentioned, one of the specific effects of mercury is to cause dilatation of the blood vessels in the tongue. This and the sympathy that naturally exists between the tongue and the rest of the alimentary tract cause the tongue to become heavily coated, flabby, and swollen. Its edges and the under surface of its tip, lie in contact with the affected gums, and therefore become infected by them. The softness of the edges of the tongue make them take the impression of the teeth against which they lie, giving rise to saucer-shaped facets with yellow purulent borders, the well-known "orchestra chair" tongue.

The very same thing that occurs on the edges of the tongue, occurs also in the cheeks. The soft mucous membrane of the cheek pouches takes the impression of the teeth, and extends as a ridge between the upper and lower sets, forming what is called the interdental line. The tonsils too, when they are hypertrophic and full of cavities in which food may lodge, may form a starting point for ulcerations.

The Complicated Etiology of Mercurial Stomatitis.—The upshot of the matter is that there are many etiologic components entering into the incidence of stomatitis and its gravity, besides the direct action of the mercury itself. There is the previous state of the mouth, the stomach, and the alimentary canal, the presence of the anaerobic bacteria and the susceptibility of the patient to their deleterious action, and the sensitiveness of the individual patient to the drug mercury itself. Intricate as the disease, hydrargyrism, is, there is a distinct advantage in appreciating these different etiologic factors and in knowing where trouble is likely to break out, as giving a greater objectivity and intelligence to therapeutic measures. The other danger of being so cautious as to render the treatment of syphilis ineffective out of fear for the remedy must also be avoided.

The severer forms of stomatitis are rarely now seen, but the milder grades are frequent, and should receive attention as indicating that the limit of tolerance for the drug is being reached, and also because intelligent treatment may add much to the patient's comfort.

Grippe as a Complication in Treatment With Mercury.—One of the accidents that may befall in giving a course of mercury is a grippe infection. The patient becomes constipated, and develops a metallic taste, and gingivitis and ptyalism supervene. The conjunctivæ may become yellow, and bile may appear in the urine. The patient feels utterly miserable. If the mercury is not stopped, severe mercurialism will almost certainly develop. In ordinary grippe a dose of calomel is given as being the best intestinal antiseptic and aperient. When this disease supervenes during a mercurial treatment, this remedy, of course, is to be avoided.

The chemical changes in our body are unbelievably swift, and the corporeal structure is held together and the initial energy is furnished by what is hypothetically called vital energy.* Some men have much of this vital force, others have very little, but whether much or little of this driving energy is present as a natural endowment of the individual, there is no common disease that will so suddenly lower it as "grippe."

When the functions of the organs work perfectly and the food is duly transmuted into energy, and the waste is cleared away steadily by the emunctories, the stream of mercury given for the cure of syphilis flows along and is uninterruptedly discharged. Let, however, the vital energies decrease, and the chemical activities of the body slow down, and the emunctories slacken in their discharges, then the mercury will accumulate and begin to act detrimentally. All these misfortunes and more too may happen as a consequence of a "grippe" infection, and time and again I have had to interrupt a mercurial treatment on account of this interloper.

Prophylaxis.—As before mentioned, mercury causes very little trouble in the mouth in infancy, but in the adult the susceptibility is so marked that the laity is well aware of it, and patients frequently ask for directions regarding the care of the teeth and mouth. In almost every case, at some time during the treatment, there will arise some irritation, generally controllable by quite simple means. In fact no one thinks of interrupting treatment because of these slight symptoms, which are regarded as signs that the patient is well under the influence of the drug. When the symptoms become more serious, however, the mercury is stopped immediately, and means are taken to facilitate its elimination and to control the oral trouble.

As a preliminary, at the very outset of treatment, the patient is requested to brush the teeth after each meal three times a day, using any of the good tooth powders or pastes, of which there are some on the market, containing chlorate of potassium, that are excellent for this purpose. As for chlorate of potassium, many men have adopted the routine of prescribing a tooth paste containing it, for no other reason than that it acts well. As we shall see later, this is a sufficiently interesting circumstance.

The brushing, however, is essential, and the clearing away of the food from between the teeth, and the depression of the gums with silk floss or a handkerchief wrapped around the finger or a pointed orange woodstick. Indeed as brushing is sometimes very painful, the orange wood stick, the finger, and the silk floss may be the only means of cleaning tolerated. Tartar should be removed and decayed teeth filled or evulsed. In florid syphilis the dentist, of course, should be warned for fear of infection.

The patients frequently become very sensitive to acids that set their teeth on edge, such as those of the citrus fruits and vinegar. This often leads them to blame the acids for the salivation, and incidentally, the physician, if he had not warned them of this contingency. It is rare, however, for a little dash of lemon or vinegar to act either disagreeably or detrimentally—when the teeth become very sensitive, of course, it is a different matter.

Moderate smoking may be allowed except when the mouth is very irritable. There is no question that alcohol is injurious. Mouth washes or drinks that are too hot or too cold should be avoided; ice water seems to be particularly harmful.

*This is also called by Prof. Benjamin Moore, biotic energy. "The Breath of Life," by John Burrows, 1915, p. 107. This change of name was introduced because the phrase "vital energy" had fallen into such ill repute.

Peroxide of hydrogen is now regarded as almost a specific in mercurial stomatitis. Nicholas mentions that it will often prevent its development, and frequently will cure one already under way. Scholtz says that as soon as the gums begin to swell and a purulent film appears, a very dilute perhydrol solution (1:500 or even 1:1000) constitutes the best mouth wash. The question as between peroxide of hydrogen and perhydrol is an interesting one. Perhydrol is a 30 per cent. solution of peroxide of hydrogen, H_2O_2, and is free of acid. It, therefore, differs from the peroxide of hydrogen solution of the pharmacopœia in being acid free, and in being ten times stronger. The addition, however, of a very small quantity of acetanalide stabilizes the H_2O_2 and enables it to be made so slightly acid as not to be hurtful, so that the difference between the two preparations, when carefully made, is reduced to a matter of strength, and as they are almost always employed highly diluted in stomatitis mercurialis this difference may also be equalized. Perhydrol has the disadvantages of being expensive, and being liable to explode. Expense under the circumstances is a matter of importance, as the free use of the mouth wash is essential.

Scholtz employs the following prescription:

℞ Sol. perhydroli, 5.00.
Aq. ad., 200.00.

M. Sig.: A teaspoonful in a half or a full glass of water as a mouth wash, several times a day.

As peroxide of hydrogen is one-tenth the strength of perhydrol an equivalent prescription would be:

℞ Peroxide of hydrogen, 50.00.
Aq., ad, 200.00.

M. Sig.: A teaspoonful in a half or a full glass of water.

This is slightly astringent and antiseptic, it cleans the mouth and gums, and dissolves and scatters the mucopurulent coating, and therefore deprives the anaerobic bacteria of their food. As occasion requires, this solution may be employed stronger.

In cases in which the margin of the gums is still more strongly affected, as in pyorrhea alveolaris, undiluted peroxide of hydrogen may be directly applied, or a mixture of equal parts of peroxide and a 20 per cent solution of nitrate of silver:

℞ Peroxide of hydrogen.
Argent. nitric. (20 per cent. sol.) aa, 10.00.

M. Sig.: Apply with a cotton swab.

Both chlorate of potassium and peroxide of hydrogen, the two remedies found so excellent in mercurial stomatitis, give off their oxygen very readily, and it may be presumed that it is to this circumstance that they, in a great measure, owe their effect in interfering with the activity of the anaerobic bacteria.

Liq. alumini acetatis, a teaspoonful or less in a glass of water, makes an excellent mouth wash and gargle.

There are several good mouth washes on the market of the same general formula as the liquor alkalinis antisepticus. A principal ingredient of these is borax, a mild antiseptic of an unctious, soothing nature. Boric acid may be used advantageously alone, dissolved in water, a heaping teaspoonful in a glass. Years ago I ran across a recommendation by Louis Brocq of adding boric acid powder to slippery elm bark tea, which makes a particularly smooth, simple, mildly antiseptic preparation in irritative lesions of the mouth. First the infusion is made by putting a handful of the bark in a moderate sized pitcher and adding hot water. After standing for some time the tea may be poured out through gauze. A heaping tablespoonful of boric acid powder may be added to a quart bottle of this infusion. If this is more than sufficient to dissolve, the residium sinks to the bottom of the bottle, and in any case can do no harm. The patient may carry a quantity of this in a flat bottle in his hip pocket for frequent use. Every author insists on the frequent employment of these mouth washes as being of the utmost comfort to the patient, and it is one of the chief advantages of the acetate of aluminium, boric acid, and of the very dilute peroxide of hydrogen mouth washes that they can be so employed, without either inconvenience or financial embarrassment.

Chromic acid, in 10 per cent. solution, is the best application for erosions. It must, however, not be used too frequently, as in that case it will irritate an already irritable condition. A swabbing every two or three days is usually much better than a daily application. Nitrate of silver, in 10 per cent. solution or as the stick, may also be used in the same way, but usually does not act so kindly. When the gums are very soft and swollen, it is best to brush them with a 10 per cent. or 20 per cent. solution of nitrate of silver followed immediately by a 10 per cent. solution of chromic acid (Scholtz).

Chromic acid may be used in yet another way when ulceration occurs. A 25 per cent. solution is brushed over the surface, followed by the application of nitrate of silver stick (Boeck). A combination of red chrome silver is formed as a crust, under which healing takes place. In larger ulcerations iodoform gauze may have to be laid between the gums and the cheeks. I have never had to employ either of these expedients, but no man can say when he will have to do so, as in giving mercury hypodermically the dose is irretrievable, and the patient may be hypersensitive to the drug. Furthermore it is well known that the most severe cases of stomatitis may occur with the inunction treatment. The two effective ways of administering mercury, therefore, are intimately linked with a possible severe stomatitis.

Tincture of rhatania, tincture of nut-galls (gallarum), and tincture of myrrh are employed for their astringent effect. They are, however, of lesser value than those previously mentioned, but may be very useful when the gums are in good order.

℞ Tr. rhataniæ.
Tr. gallarum, āā 15.00.

M. Sig.: Fifteen to twenty drops in a half glass of water as a mouth wash.

Eliminatory Treatment.—The elimination of an offending substance must be fundamentally more important than the control of the symptoms it produces. This axiom holds as good for mercury, causing a severe stomatitis, as for any other foreign body. The first step to be taken, therefore, is to stop the drug, and if inunctions have been employed, to give a hot bath with plenty of soap to free the skin of the mercurial ointment. Some would add Vleminckx' solution to this bath in order that the inert black sulphide of mercury may be formed. The essential, however, is the water, the soap and the scrubbing to free the skin of the mercury, and so to stop absorption and inhalation.

Formerly the impure sulphuret of potassium, called "liver of sulphur," was much used for sulphur baths, but now Vleminckx' solution is generally preferred. This solution is made by adding quick lime to sulphur and boiling it down:

℞ Sulphuris sublimati, ʒv.
Calcis vivæ, ʒxx.
Aq., ℥l.

Boil together with constant stirring until the mixture measures ʒxxx. This is sufficient for about five baths.

One hundred and fifty to two hundred grams, or five or six ounces, are added to a bath. The two disagreeable features of this bath are its evil odor and the way it blackens a metal bath tub. The advantage to be reaped in fixing the metal mercury as the black sulphide is very small, as all the metal attainable on the surface can be removed by a bath of soap and hot water.

The rate of the elimination of mercury varies greatly in different cases, and the reasons for the variability are usually unascertainable—one of them, however, an attack of la grippe, has been previously discussed. There seems to be no doubt that the chief emunctory is the intestinal canal. Vogel, and Lee, for instance, recently have found that, in cases of bichloride of mercury poisoning, the mercury persisted longer in the feces than in either the stomach washings or in the urine.[3]

The next measure, therefore, after stopping the drug, is to see that the bowels are acting properly. A dose of castor oil may be given as the best cleanser of the alimentary tract, and this should be followed by a steadily acting laxative, such as senna or rhubarb, which may be advantageously combined with a diuretic:

℞ Pot. acetatis, ʒv.
Ext. sennæ fl., ℥ii.
Aq. gaultheriæ ad., ℥iv.

M. Sig.: A teaspoonful in a little water p.c.tid.

To give a diuretic and not to give abundance of water is like putting a mill wheel in a dry mill race. The patient, therefore, should be advised to take warm drinks in plenty. The value of the various teas rests probably in the fact that many people cannot take plain warm water without nauseation. These teas set the skin as well as the kidneys in action, and if to this ingestion of hot water there is added a hot bath with a subsequent rest in bed of two hours to encourage perspiration, much will be accomplished.

Here may be mentioned the administration of atropine as a hypocrinic. A hypocrinic is a drug that lowers the secretory activity of a gland, and for this purpose the use of belladonna and atropin have been advised to control the tormenting salivation. If, however, these drugs are given to lower the activity of one set of glands, they just as surely lower activity in others, and therefore interfere with the intestinal, renal and cutaneous elimination of mercury. Furthermore the effect of these drugs on the salivary glands is apt to be very little, whereas their general effect on the entire secretory system may be quite pronounced, and therefore more harm than good may easily be accomplished by their employment. All the other hypocrinic or inhibitory drugs are in the same catagory. Many men, for instance, prescribe opium with mercury as a routine practice in giving mercury by the mouth, with the double purpose of preventing a diarrhea and of allowing the mercury to accumulate in the body. It is not, however, the mercury that accumulates in the body that does the good, it is that that actively changes into a form noxious to the spirochete and then passes through, carrying with it the peccant materials. The action is, therefore, spirocheticidal and eliminatory, and any interference with elimination is detrimental both in the treatment of syphilis, and in any of the accidents produced by mercury.

In reflecting on the phenomena of mercurial stomatitis one cannot fail to be struck with their intimate connection with the teeth. Sensitiveness of the teeth is one of the first symptoms; the trouble is most apt to begin in the neighborhood of the teeth; the condition of the teeth is of the first importance in the incidence of the symptoms, absence of the teeth secures a comparative immunity, and the treatment is largely directed toward the care of the teeth and gums.

THE CARE OF DIGESTION.*

BY MAX EINHORN, M.D.,
NEW YORK.
PROFESSOR OF MEDICINE AT THE NEW YORK POSTGRADUATE MEDICAL SCHOOL.

DIGESTION deals with the processes of food ingestion, assimilation, and ultimate waste elimination. Health and life are dependent upon the harmonious working of the digestive apparatus. Its disturbed function creates disease; its interruption for a longer time carries death with it.

It appears worth while to consider here some of the points which serve to keep the digestion in good shape, in order thereby to preserve health.

For this purpose we may divide our subject matter into the following items: (1) Food intake: quantity required in growth, manhood, old age; (2) State of the body for this act; (3) Period of assimilation; (4) The final act of waste elimination (defecation).

The quantity of food required is very definite and is greater in the period of development and manhood than in middle age or old age. During the time of growth a large quantity of the nourishment is utilized for the upbuilding of the body. In manhood the greatest activity is manifested, and this again requires additional nutritive material. In middle and advanced age the activities are gradually reduced and the food requirements are accordingly lessened. With the beginning of middle age there is often a tendency to corpulence; for occasionally at this period with the reduction of work there is no decrease in the quantity of food intake. The surplus of nutritive material is then stored up in the body in the form of fat.

The diet should be watched and arranged somewhat differently for these different periods of life.

In most instances in health our instinct guides us correctly and the appetite is a sufficient monitor to go by. Transgressions may, however, occur in both directions by faulty habits (overeating on the one hand and too scanty nutrition on the other). Thus opulence and high living give rise to an overabundance of the food intake, while poverty and avarice in the parent's house or in the boarding

*An address delivered before the employees of New York City, October 11, 1916, at the Municipal Building, New York.

establishment may lead to subnutrition. Both hypernutrition and subnutrition practised for a longer time may become established as a habit, *i.e.* the appetite here becomes deranged and is no more a fit guide for the best purposes of the organism.

In order to look for good health we must guard against either of these faults.

How shall we know whether we eat just right? The quantity of food physiologically required is known, and for the physician it is a simple matter to make a computation and to state whether somebody eats enough, too much, or too little.

The layman, however, can likewise easily find the right measure. First, his appetite may be used as a guide; second, everybody should eat about as much and as often as his neighbors and associates; third, everybody can see whether his body and strength are in good condition. If everything is harmonious and goes on smoothly, this alone is sufficient. If not the scale may be utilized and weighing yourself once a week or so will soon show whether there be too much or too little food taken.

What kinds of foods should be taken? Here, again, the answer is: look at your neighbors, do the same, and you will not go wrong.

The following rules may, however, be given in a general way. Arrange for a great variety of food, which should embrace most nutritive substances easily digestible and also difficult of digestion. To select a diet in health consisting merely of easily assimilable foods would be a great mistake as it would serve to decrease the efficiency of our digestive apparatus.

Eating being one of the most important functions of the organism should not be done haphazard, but performed with care. A moderate amount of work preceding the meal increases the appetite and enhances the digestive function.

A few more rules regarding diet in health may here be added. There is a tendency in this country toward eating too much meat, which often leads to constitutional disturbances. Some people here take meat regularly at each meal. As a rule meat should be partaken of once or twice daily in quantities of about one-quarter of a pound for an adult, but not much above this. Plenty of vegetables should be served with it. Bread and butter, fruits, and salads should be used liberally. Water should be taken with each meal, and if thirst be present also in between. Its importance cannot be too much appreciated.

Water itself is one of the principal ingredients of the organism. It contains, besides, in small quantities, mineral salts of different kinds which are utilized in the body economy. Food digestion, assimilation, and elimination require for these processes water as an intermediary, without which life is impossible. Fresh cool spring water at meal time increases the appetite and augments the pleasure of eating.

Too great fatigue destroys the appetite and banishes the joy of eating. The latter is then done mechanically, almost with disgust, and the process of digestion is thus disturbed right from the start. During meal time rest of the mind and body is essential. A comfortable seat, a nicely set table, pleasant company, wholesome food and drink (fresh spring water) are important factors in increasing the worth of the meal. General conversation not requiring much concentration of mind is rather useful. Direct business talk should be avoided. The meal should be ingested leisurely and time given to the enjoyment of the different courses (food articles). The eating should be performed neither too quickly nor too slowly. Both deviations lead to manifold digestive disturbances. A short period of rest following the meal is advantageous. A mild cigar and pleasant conversation contribute toward the enjoyment of this after-table act.

The real act of digestion begins after the ingestion of food. The alimentary canal may be likened to a factory in which all the material brought in is sorted and changed in such a manner that it can enter the circulation and by means of that stream of communication reach all the body tissues.

Assimilation of Food.—Unfit substances or the remnants of food which cannot be utilized any more are carried along the digestive canal to be eliminated at the end. The tissues of the body likewise throw off dead or waste material. They accomplish this through the eliminative systems (lungs, kidneys, skin, and alimentary tract, including the liver) reached by all the tissues through the blood stream. The digestive canal is thus one of the principal avenues for the traffic also of waste products of the body itself.

The assimilation is greatly favored by keeping the body in good trim. For this the organism must be in a state of contentment, which can be reached by satisfactory mental and bodily work. Every occupation should be performed with a good will and pleasure, and should not be carried on to overfatigue and annoyance. Thus assimilation will be helped and good health made possible. Plenty of fresh air and a certain amount of muscular exercise (walking, horseback riding, rowing, gymnastics) are of importance. In the same way after the working hours rest and a sufficient amount of sleep (eight hours daily) are essential for good digestion and perfect health. Both exercise and rest, properly apportioned, enhance assimilation as well as elimination.

The final act of digestion consists in the expulsion of all the remaining unutilizable food substances and some waste products from the alimentary tract (defecation). This usually occurs once daily in normal individuals. Regular attendance to this natural event is likewise important for the well-being of the organism. With regard to this act the call of nature should be obeyed at the right time. Frequent neglect to perform this duty as well as too much devotion to it lead to irregularities of the bowel and ultimately to ill health. In health the best principle is to let things take their natural course. Too much interference with it often leads to abnormal conditions and disease.

To sum up, the care of good digestion embraces the following items: simple life, in which work and rest for mind and body are harmoniously divided; regularity of meals, frugality, great diversity of wholesome foods taken, in just the right proportion; an abundance of water; proper attention to the call of nature. Good digestion is also the best promoter of good health and a long life. There is no elixir of youth for old age, or a rejuvenation remedy. In keeping our organism, however, in good trim, in looking out for its steady and harmonious activity, we succeed in delaying and perhaps also shortening the advancing state of invalidism and the dissolution period, with death at its end.

Life is not complete without death. The latter is a natural event at some time for each living being and its advent should not be begrudged.

AMBULATORY TYPES OF THYROID DISEASE.*

By ELEANOR BERTINE, M.D.,

NEW YORK.

SHELDON FELLOW IN MEDICINE, CORNELL UNIVERSITY MEDICAL COLLEGE.

In the last eleven months 134 cases of thyroid disease have passed through the Cornell Medical Clinic. As in dispensary practise in general, they have been, for the most part, patients with the less serious manifestations of the trouble, the large majority belonging to that most obscure class, the formes frustes. However meager our knowledge of real Graves' disease may be, it is a flood of light compared with our understanding of the processes taking place in the organism to produce these aberrant conditions. While the laboratory attacks the subject of their cause from the experimental point of view, some light may be shed upon the problem by a more careful observation of the demonstrable results as shown in the clinical pictures presented. With this end in view a study has been made of the material seen in the Cornell Thyroid Clinic.

For every new admission during the year a chart, such as here shown, was filled in, and at each subsequent visit a careful record has been kept of the progress in respect to pulse, weight, circumference of the neck, blood pressure, tremor, and the patient's own statement of how she feels, with, of course, the treatment. For this purpose the second blank was used.

First, a word about the patients. A small majority were American-born; of the rest Russian-Jews and Austro-Germans were numerous, with only an occasional representative of the Irish, Italian, and other nationalities. Practically all were women, half the number being single and half married. Most of the married women kept house and had children. The single patients were about equally divided between school-girls, girls engaged in some semi-domestic occupation, as sewing or domestic service, and workers in miscellaneous industries. Though all were poor, there was comparatively little destitution among them.

Clinically, there was found the greatest variety of combinations of signs and symptoms. An attempt to classify some order into this confusion revealed a serious difficulty, namely, the inadequacy of our ordinary classifications. There were a few cases of real Graves' disease, many cases of partial Graves' disease, no cases of true myxedema, some cases vaguely suggestive of myxedema, though differing from it in many essentials, and a large number combining the elements of a partial Graves' with a suggestion of myxedema in a way that no mere variation in the quantity of thyroid active principle could account for. An attempt to classify our cases as vagotonic or sympathicotonic according to the work of Eppinger and Hess† gave no more illuminating results. There is still much doubt as to which division of the vegetative nervous system is responsible for many prominent symptoms. Then, too, even accepting the conclusions of these workers in this regard, very few of our patients fell wholly or even predominantly, in one class or the other, but combined symptoms and signs of both to such a degree that the picture was more confused than simplified.

*From the Medical Clinic of the Cornell University Medical College in New York City.

†Eppinger and Hess: Vagotonia, Nervous and Mental Disease Monograph, Series No. 20.

So discarding all preconceived ideas and focussing attention only on the patients, an attempt was made, finally, to see some principle on which a sound division could be made, a principle that should not pretend to explain or assign causes, but which should be so true to facts that it could be used when the time comes to help test explanations and theories of causes. Aside from nine simple goiters without symptoms, the patients fell clinically in to (1) those in whom stimulation was the chief factor, stimulation of metabolic processes, of the nervous system and heart, and (2) those in which functional depression was the outstanding feature. In addition there were all intermediate gradations and combinations of the two conditions.

The first group, or nearly half the total number, can be quickly dealt with because it presents the well-known syndrome of hyperthyroidism. All these patients had a goiter, usually small or moderate in size, tremor and nervousness. The increased metabolism was shown by loss of weight, tendency to elevation of temperature, and the compensatory mechanism of sweating. One-half were poorly nourished and nearly two-thirds complained of sweats. Three per cent., however, were over-stout, but these were all middle-aged women who had had the disease in a mild form for years. More or less exophthalmos occurred in 70 per cent. of the cases. All the pulses were irritable, running up abruptly with the slightest exercise or excitement, and in addition most of them were rapid, 72 per cent. being over 100. There were a large number of young girls in this class, 37 per cent being between 10 and 20 years of age, with the number in each succeeding decade progressively falling. Menstrual disturbance though occurring in some slight degree in 45 per cent., consisted in half the number of only a reduced or retarded flow, and hence was not prominent as a complaint.

The second group contained those characterized chiefly by depression of function. There were 27 of them, well-nourished, a majority in fact over-stout, usually with good color, yet complaining bitterly of weakness. This symptom stood out above all the rest, and was the thing for which 90 per cent. primarily sought relief. This is in marked contrast to the hyperthyroid group, in which, though it included two bad cardiacs, two recent operative cases, and all the very sick people, only 26 per cent. complained of weakness. Though largely subjective, expressing itself in easy fatiguability, disinclination for mental or physical exertion, loss of concentration, and emotional depression, there was also definite muscular relaxation that was evidenced by posture and abdominal flabbiness, often with visceroptosis. With this were associated frequent headaches in 85 per cent. of cases, constipation in 71 per cent., and in 78 per cent. a distressing sense of pressure in the neck or choking sensations, which had no apparent relation to the size of the goiter or the probability of its interfering mechanically with surrounding structures. Menstrual disturbances were the rule, and were very troublesome. There were more large goiters among these patients than among the previous group, the age tended to be older, and the duration longer. This, with the tremor so frequently present, suggested the possibility that the depression phase might be a late sequel to that of stimulation. In a few cases this appeared to be true, notably in two in whom a slight exophthalmos occurred, but the great majority gave a history that could not fairly be so in-

terpreted. However, some of our own hyperthyroid cases appear to be going through this transition while under observation, so it probably does occur.

Thus far the cardinal symptoms, asthenia, physical and mental fatiguability, headache, intestinal sluggishness, and choking sensations, might be attributed to a hypothyroid condition, and doubtless this plays a part in producing the picture. However, there are some important differences. The patients do not look myxedematous; they lack the pallor, the apathy, the somnolence, the falling hair and thinning eyebrows.* They are alert enough, generally have normally moist skins, pulses that average about 82, and not one had the slightest sign of the characteristic infiltration of the skin.

Perhaps the most conclusive evidence that the condition is not so simple as a mere thyroid deficiency is the combination of the symptoms of the latter group with those of hyperthyroidism in every conceivable arrangement. Thirty-three cases of the series were thus classed as intermediate, each patient having symptoms belonging to both types. For instance, nervousness, tremor, more or less emaciation, and irritability of pulse may be associated with lassitude, inertia, emotional depression, and headaches. Or again, there may be on the one hand, tachycardia (120 or more) and sweating, and on the other, obesity, constipation, and asthenia. A case history will illustrate the combination.

Mrs. M. Age 26, a Roumanian Jewess, married but with no children, has had, for nearly two years, a small goiter, some exophthalmos, and a marked tremor. She is very nervous, poorly nourished, and is slowly but constantly losing weight. Her pulse is moderately accelerated, 108, and she sweats considerably, though able to do light housekeeping. So far, a pretty straight case of mild Graves' disease. But in addition, she complains of great weakness, headaches, constipation, almost constant choking sensations, and dysmenorrhea, except for the poor nutrition, an equally complete picture of the opposite type.

A few cases have come to the clinic after having a partial thyroid lobectomy. The tachycardia, tremor, and exophthalmos remain, but the operation has been followed by a marked gain in weight, even to the point of obesity, headaches, choking sensations, asthenia, and constipation. There is here an extrathyroid element, probably adrenal or pituitary. Somehow the balance between the thyroid and the other endocrine glands has been upset.

Summary and Conclusion.—1. Of 134 cases of thyroid disease, there were: (*a*) Nine simple goiters; (*b*) sixty-five cases in which stimulation from excessive thyroid activity was clinically the chief feature; (*c*) twenty-seven cases in which depression, physical and mental, was the chief feature; (*d*) thirty-three cases in which there was a mixture of stimulation and depression.

2. Simple quantitative change in thyroid secretion is inadequate to explain groups *b* and *c*, but the cause must be sought in some at present ill-understood incoordination between several endocrine glands. Hence of 134 cases of thyroid disease, at least 60 present features of a complex endocrine disturbance.

CONGENITAL CLUB-FOOT.

CLINICAL STUDY OF A SERIES OF 21 CASES WITH REMARKS ON TREATMENT.

By I. REITZFELD, M.D.,

NEW YORK.

ASSISTANT SURGEON, HOSPITAL FOR DEFORMITIES AND JOINT DISEASES.

THIS report is based on a study of 21 cases, seen at the clinic of the Hospital for Deformities and Joint Diseases and from the services of Drs. H. C. and H. W. Frauenthal, whom I want to thank for the privilege of reporting same. This study must be considered purely preliminary in character. For the purpose of simplicity and aid in reaching conclusions, a history form was gotten up, presenting a number of important data.

Each case on the first visit to the clinic was made the subject of the following inquiries: The name and age, the character of labor, the question of hereditary taint, the time when the deformity was first noticed, the presence of associated congenital abnormalities, the type of deformity, whether single or double, etc., were all noted. Later on the method of treatment, and the complications, if any, were also considered. Each patient was photographed, and where absence or deficiency of bone elements was suspected radiographs were taken. In this series there were 21 cases, taken as they came and unselected. Of this number 12 were males and 9 females. The ages of the deformed ranged from 10 hours to five years.

To enable us to consider the question of traumatism during birth, the character of the labor was carefully gone into. Of the series 19 of the cases had perfectly normal births and in the remaining 2 the delivery was instrumental. So that it is fair to assume that trauma plays a small rôle, if any, in the production of this condition. The question of heredity is a rather interesting one. In the series only one case gave a definite history of a familial tendency. In the case of M. G., an older child of 10, was afflicted with a similar deformity. This case is rather of unusual interest and will be reported in detail further on. Personally, I feel that hereditary predisposition is a factor, a contributing one, perhaps, and not a direct cause.

In all but two of the series the deformity was noticed soon after birth; in one case it was not observed until the third day and in the other one week following birth. It may be safely said, however, that the deformity in both cases was undoubtedly congenital, for all other etiological factors can be excluded. It was interesting to note that in this series 5 cases presented associated abnormalities. In case of M. L. there was a fusion of the third and fourth toes on both sides. Case of T. B. presented an anomalous condition of the small toes of both feet. The metatarsophalangeal articulations of these toes were perhaps one-half inch posterior to the normal situation. Case of M. L. revealed a congenital constriction about the second finger of the right hand (amniotic adhesions). Case of M. G. showed congenital malformation of the left ear, and case of H. Z. presented congenital dislocations of the fourth toes of both feet, at the metatarsophalangeal joint line.

A rather frequent condition that I noticed in a number of the cases was the relative smallness in size of the big toe in the affected foot. Whether this is to be considered an abnormality or not I am unable to state.

The types of talipes as seen were as follows: Equinovarus numbered 15, ten of which were bilateral. Of the five single deformities three involved the right foot and two the left one. Three of the cases in the series were pure varoid in character. All were bilateral. There was one case of calcaneus affecting the left foot and two cases of valgus. Of the latter one was double and the other single, involving the right foot.

Anatomical Observations.—Inspection of the afflicted members presented a number of points. In all of the cases seen the heels were found small and when there coexisted a contracted tendo Achillis a fold just above the heel was always encountered. These folds were also observed about the ankle, on either side, depending on whether a varus or valgus deformity existed. In talipes varus the folds were found on the inner side of the foot, and in valgus on the opposite side. As correction of the condition progresses one notes the appearance of the folds of the skin onto the opposite side of the joint, and at the same time an associated stretching of the original folds.

In talipes equinovarus the outer border of the foot assumes a curve with its concavity facing the median line. A few cases in the series presented marked displacement of the astragalus. This is of great importance. Until this displacement is corrected, no true and stable cure is obtainable—at least that has been my experience. Indentations or dimplings were encountered a number of times. These have been seen on the soles and inner border of the feet. They are supposed to be due to amniotic adhesions.

Treatment.—The treatment to be described is according to the method in use at the clinic of the Hospital for Deformities and Joint Diseases. No claim for originality is made. It consists of three fundamental principles—correction, retention, and supervision.

Correction is obtained by manipulation, with especial effort toward replacement of any existing faulty position of small bones of the foot, especially the astragalus and cuboid. The earlier treatment is begun the better the prognosis as to a cure. Each foot is manipulated for a period of about five to ten minutes, following which the limb is fixed in the corrected position. For the purpose of retention we use first adhesive straps, followed by plaster of paris. The patients are instructed to return at least once a week, the dressings, however, are changed about once in two or three weeks, when the same process is gone through. This in brief is an outline of the treatment for talipes in general. The different types, however, require special considerations.

Talipes Equinovarus.—After manipulation a primary roller of gauze (one inch bandage) is applied from the toes to the knee. This is to fit snugly, each turn overlapping the previous one. Care is exercised not to leave any exposed and uncovered areas, as these make fruitful soil for ulcerations. With the deformity corrected as much as possible, and the gauze roller applied, the next step consists in holding the acquired position by use of adhesive straps, usually one or two in number, rarely three. These straps are about one-half inch wide and from 4 to 7 inches long, depending on the size of the leg. They are applied from within outward and should partly overlap. They should be long enough to go beyond the knee. A second roller bandage is now applied in a similar fashion as the first. This helps to

maintain the adhesive straps in the desired position. When the knee is reached the adhesive straps, which extend beyond the joint, are then reflected and kept there by a few turns of bandage. Over this a thin light cast of plaster of paris is applied. A one-inch bandage is usually found sufficient.

Recently we have modified the above to the extent of adding and incorporating in the bandage or dressing a thin wooden splint, measured to the size of the sole of the foot and so applied. The object of this is to prevent a narrowing of the forepart of the foot. Before applying the splint it should be well padded.

After correction of the deformity is obtained the feet are placed in very light metal braces which are easily removed, so as to allow for massage. This is applied especially to the peroneal group of muscles. At this time the patients are instructed to return three times a week for massage treatments. When the child has reached the walking stage, proper shoes are ordered and so constructed as to force the feet somewhat into valgus position (elevation of the soles on the outer side with a small pad under the arch to prevent breaking down completely. In other words, to prevent flat foot). From now on the case is supervised to prevent relapse.

In those cases where manipulation is not sufficient to overcome the equinus position, the patient is referred to the hospital for surgical relief (tenotomy, tendon lengthening, etc.) But this takes the patient from the clinic and I shall not describe these measures.

Talipes Varus.—Treatment consists in the same measures as used in overcoming the varus deformity in equinovarus, and as this has been described no further mention is necessary.

Talipes Valgus.—In this condition manipulations to be used are the reverse of those in varus deformity. It is a good plan to apply any bandage that may be necessary from without inward. This aids in overcoming the valgus. The same holds true to the application of adhesive straps. They should be started on the dorsum of the foot, running outward over the external border of the foot, across the sole and then up alongside the inner margin of foot and leg. When the stage of correction has been reached and massage is indicated, this is to be directed mainly toward muscles of the legs, which, when active, produce inversion of the foot. Shoes, when ready to be worn, should be constructed so as to throw the foot into a slight varus position (inner side of sole raised).

Talipes Calcaneus.—In this form, the foot is dorsiflexed on the leg at an acute angle. On the dorsum one may see folds of skin. The dorsiflexor muscles are found shortened and the extensors lengthened—notably the tendo achilles group. In the one case of calcaneus in the series, it is possible with just the merest use of force to dorsiflex the foot so that the toes actually touch the front of the leg.

For the relief of this type we use a malleable metal splint, well padded. This splint is applied so as to increase the angle of dorsiflexion. It is applied posteriorly, extending from a distance a little above the knee to the toe line margin. The part is first manipulated in such fashion as to stretch the contracted or shortened anterior group muscles and to shorten the calf muscles, then a gauze roller is applied. The splint is then fitted to the limb, bent at the knee, and at the ankle. In the latter position it is bent so as to keep the foot in equinus. The knee is taken in so as to allow for greater correction of the deformity. The splint is held in position by another gauze roller and this is followed by the application of a plaster case.

When correction has been obtained massage, especially directed to the calf muscles, is instituted. The part is then redressed as above described with a plaster of paris splint (removable). This is done to enable one to remove the dressing easily. When the child begins to walk, it may be advisable to elevate the heels of the shoes somewhat. This has a tendency to maintain the equinus position.

For the correction of different types of club foot I have found that the average time is about four months. Occasionally delay in cure is caused by intercurrent infantile diseases and complications due to the correction of deformity. In one of the cases (equinovarus), as a result of faulty application of corrective dressings, pressure sores developed on the anterior surfaces of both ankles. It took ten weeks to cure these, leaving ugly scars.

The results obtained at present writing may be spoken of as cured, improved, and unimproved. By cured, it is to be understood that stable correction of deformity has been obtained. By the term improved, some correcting has been obtained, but not entirely so. The designation unimproved refers to those in which no change for the better has resulted. In this latter class I have included those cases in which treatment has been given for a short time and in which no change is yet to be expected. Among the cured there were five cases of equinovarus and one of calcaneus. Two cases of equinovarus, one of valgus, and one of varus were improved. Seven cases were unimproved, of these two were equinovarus deformities, one valgus, and four were of varus type.

After all is said and done, the correction of deformity is accomplished in a comparatively short time, a few weeks or months, but the result can be determined only after constant and active supervision for two or three years following so as to guard against relapse.

57 East Ninety-sixth Street

A FOUR YEARS' STUDY OF THE KELLING HEMOLYTIC TEST.

By B. G. R. Williams, M.D.,

Paris, Illinois.

About four years ago I became sufficiently interested in the promise of Kelling's hemolytic reaction to undertake tests with a view to diagnosis. The first of these was set up on September 18, 1912. This test was positive. At the time I warned the people that the reaction was still in the experimental stage and could not be regarded as specific. The patient was alive nine or twelve months after that date and consultants were of an opinion that the growth was after all a benign one. The patient agreed to an operation. Exploration, however, revealed an inoperable tumor mass and the patient died within a short time.

Meanwhile I had refused to undertake further tests until convinced that the results of this first one had not been misleading. Led to believe that the test might have a clinical value, I then adopted it as a laboratory procedure of probable worth and have applied it, not routinely, but in cases selected according to the conditions noted below.

The number of tests made under these conditions

is 90. About 100 other tests might be added were I to count controls and reactions used for study, mainly in normal cases. I have no apology to offer for a report on so apparently small a number for the reason that the selection of sera was not haphazard from hospital wards and so on, but in every case there was some good reason to regard malignant neoplasm of the abdominal viscera as a possibility. I might say, however, that this reason was sometimes merely the fact that some physician had suggested cancer, although we saw no real clinical signs or symptoms confirming such a diagnosis. According to available reports one or more of the "positives" are still alive since tests set up several months ago, but in general the results have been so convincing as to prompt me to make at least the following brief conclusions as to the value of the test.

Probable Value of the Kelling Test.—My experience seems to prove that when properly applied and interpreted the Kelling test is of value in the diagnosis of cancer and especially in the differential diagnosis of benign and malignant abdominal neoplasms. As a routine procedure for the diagnosis of all cancers in all stages it is practically valueless and misleading.

The value of the hemolytic reaction in my hands may best be expressed in the words ventured by me about four years ago:[1] The so-called "exploratory operation" is becoming altogether too frequently applied in cases which are probably fatal and inoperable. The chief promise of the hemolytic test is that of preventing hopelessly developed, necrotic, and metastatized abdominal tumors coming to the operating table. On numerous occasions I have witnessed these cases, and no pen can paint the horrible picture of the ubiquitous, rotting masses of daughter tumors revealed. It seems to me that in such surgery there is little actual reward, and any test which promises to illuminate will be most acceptable to a conscientious surgeon. Any abdominal malignant tumor of several months' growth or one which is palpable is invariably inoperable, and if the malignant nature is known it requires not even a glance into the belly to prove that it is too late for the knife. As a matter of fact, the exploratory operation is not ordinarily attempted to determine whether or not it is too late to operate, but whether or not the growth chances to be benign and can be removed by virtue of this fact. The case is altered, of course, when certain indications suggest (regardless of malignancy) that a gastroenterostomy is to be done to relieve the patient.

Workers apparently agree that the sera of patients with late malignant neoplasms of the viscera invariably cause hemolysis of alien corpuscles, and that this hemolysis is usually prompt and marked. More interesting and valuable than this is the fact that the sera of patients with *benign operable tumors do not cause hemolysis unless the test be applied very late indeed.* It has been claimed that when certain techniques are used (not that of Kelling) the sera of patients with advanced tuberculosis, syphilis, and so on, bring about these reactions; but such conditions are likewise not operable, and the value of the test, even though judged by an incorrect application, is not limited by these possibilities. So also pernicious anemia and nephritis (easily differentiated by blood and urine examinations) may, according to some techniques, cause hemolysis, and these conditions are likewise inoperable. Suppurations, it is claimed, may also produce positive sera, but such conditions do not usually enter into the differential study of benign and malignant tumors and may be regarded as no greater source of error than a positive Wassermann in a case of scarlet fever. Moreover, if Kelling is right the hemolytic properties of the sera of pus cases are lost by raising the temperature to a certain degree, while those of the cancer sera are retained, and we have thus a very accurate method of differentiation.

It would not, perhaps, be just to ignore all of these claimed exceptions. But keeping in mind the countless variations (most of them uncalled for) in technique which have characterized the work of our American investigators, and the constant results noted above, certainly the future promises much for the reaction, at least in those circumscriptions of diagnosis which I have indicated.

In brief, therefore, I suggest that the questioned positive reactions given by other sera include chiefly the nonoperative conditions, and these are usually diagnosticated by other methods and do not enter into the special differential question. They should not detract from the main proposition that if the serum of a person (who has been affected for several months with a condition which *may* be malignant, and if so is certainly by this time inoperable, but even at this late hour the possibility that it is benign still exists) invariably brings about a prompt and marked hemolysis of standard suspensions of alien corpuscles we should not hope to find at operation benign fibroids, simple peptic ulcer, or other condition easily remedied by the knife, and we should hesitate to approach surgery which promises so little. We do a great injustice to the patient when we recommend such surgery.

Selection of Cases.—I would hesitate to propose binding rules for the selection of cases. Now and then with our greatest care we will deny the test to the patient who would be served the best by its application. I have touched upon some of the main points when considering the value of the reaction. The following suggestions may be added:

1. There must be some reason to suspect abdominal neoplasm—a palpable tumor, cachexia in a good subject for cancer, an unexplained and suspicious stomach history, a suggestive gastric analysis, a diagnosis of malignancy proposed by another clinician, and so on.

2. Essential anemia, nephritis and so on should be ruled out by proper laboratory examinations before undertaking and interpreting a hemolytic test. Rule out tuberculosis if possible, although some cases of abdominal tuberculosis may be regarded in a class with cancer so far as surgical treatment and prognosis are concerned.

3. The hemolytic test should be preceded by the use of *x*-ray and gastric analysis in questioned stomach cases and by a diagnostic examination of curettings in uterine cases.

4. It is not necessary to be able to palpate the abdominal tumor, though it is much better and usually possible to do so by the time the advisability of the test is considered.

5. Do not hesitate until the tumor is very large, for it is conceivable that hemolysins may arise by virtue of retrograde changes in enormous benign growths denied proper pabulum. This introduces a very dangerous source of error.

What Is the Hemolytic Test?—Kelling found

that there exist in the blood sera of patients affected with malignant disease certain substances or a substance innately capable of destroying the red blood cells of organisms not cancerous, but only to a limited extent the red cells of the cancerous patient, the latter appearing to be immunized (if such a term is proper) to these bodies.

Furthermore, these cancer sera rapidly hemolyze erythrocytes of chickens and other aliens, whereas normal sera have but little effect. The precise nature of the cancer hemolysin has not to my knowledge been accurately determined. Wade has shown that it is poisonous. It is especially plentiful in cancers of the mucous surfaces—stomach, intestine, etc. It may be a toxic protein remnant. Again it may be a salt or salts of certain fatty acids (cholesterin or sodium salts of oleic acid) which have been shown to have hemolytic properties.[2]

Claims of Kelling.—The first communication of Kelling appeared about nine years ago,[3] and subsequent reports by him concerned mainly case reports and technical modifications rather than any change in opinion regarding the value of the reaction. He claims that when the test is properly applied it is specific for internal cancer even in its incipiency, and that the reaction depends upon the presence of antibodies in the serum capable of causing hemolysis of the corpuscles of the hen irrespective of the location of the growth, its structure, or any retrograde changes which may be taking place in its cells. I am unable to verify or refute this broad claim, being denied the use of material in a charitable institution or an endowment to make possible such an undertaking in my laboratory. The claim of the originator of the hemolytic test should not be lost sight of, but cannot be considered in this paper.

Choice of Technique.—Instead of adhering to an original technique long enough to prove the value of a reaction, laboratory workers (and especially those of this country) begin at once to modify and "improve" upon it, with the result that many good tests are "botched up" and dropped in disgust. This has been the case with the Kelling test. It is to the shame of our workers that there is today no standard or universal technique for the hemolytic test. Four years ago I made a plea for such, and so far as I know I am the only man in this country who still adheres to the technique as proposed by Kelling. Modifications have been empirical, uncalled for, and entirely stupid, and it is not difficult to understand why the reaction has never gained a place in the average diagnostic laboratory. Parenthetically, I might say that Kelling has modified the technique somewhat, but the changes are not sufficient to subtract from the value of the original method nor the cases he examined by that method.

Preparation of Serum.—All operations should be carried out under aseptic conditions, not because the reaction depends upon the isolation of microorganisms in pure culture, but because a number of hours are necessary and some of the materials (citrate, etc.) may spoil. Secure blood from the patient in a sterile test-tube. Fifty drops are sufficient in a possible case of cancer, where we do not wish to deplete the circulation. Where a normal individual must supply serum for several controls the blood may be secured from a vein by a needle. For a single control the finger is cleaned with alcohol and pierced with a Moore spring lancet. I do not usually separate the serum by mechanical methods as by centrifugalization, but merely slant the tube and place upon ice. Keep it there for twelve hours. Then draw off the serum carefully with a sterile pipet and dilute 1:10 with physiological salt solution (formerly we did not dilute, but used practically the same amount of the serum in the end as contrasted to the corpuscle suspension). Empirically we now incubate for 24 hours at 37° C. This is claimed to render inactive certain lysins and inhibiting substances which might be present in noncancerous sera and yet not affect the cancer-produced hemolytic substances. In most of my work I have used also nonincubated serum, and the results have been about the same. Personally, I have seen no advantages thus far in incubation before mixing with corpuscles. The serum is now ready for use and should not be set aside, but the corpuscle suspension should also be ready at this point for making the test.

Preparation of Corpuscles.—With a pair of small, sharp-pointed shears open a blood-vessel on the under side of a hen's wing. The hen should be healthy, and it is best to pick a fowl known to have been healthy for several months. I select a good laying hen, and by keeping my own stock am assured that it is healthy. In case the hen is purchased just before doing the work it is best to kill it and be assured that the viscera are free from sarcoma. Receive the fresh blood directly into a vessel containing 2 per cent. sodium citrate solution. This prevents coagulation and is preferable to defibrinating with glass beads, because the latter method injures the red cells and thus favors hemolysis. Centrifugalize. Draw off citrate and substitute physiological salt solution. Repeat this process several times until the corpuscles are entirely washed. It is best to centrifugalize slowly, which avoids adhering of corpuscles into a mass, for the breaking up of such a mass injures the cells and favors hemolysis. Finally add enough or subtract enough supernatant salt solution to approximate a 5 per cent. suspension, again mix by inverting the tube, and this second component is ready for use.

Technique.—Slender serum tubes are used. In each place 10 drops of the corpuscle suspension. To one or more add equal part of the iced, diluted, incubated, unknown serum. To others add equal part of the iced, diluted, incubated, normal serum. To still others add equal part of physiological salt solution, and yet others equal part of distilled water. If at hand, serum from a cancer patient may likewise be used to control. Place tubes in rack and incubate from 24 to 48 hours at 37° C. Each tube should be tightly corked and inverted hourly, providing for thorough mixing.

Readings.—Hemolysis is most marked in the tube containing distilled water. It is marked in the sera of patients with late growths. We have found it most marked in cancers of stomach, intestine, and uterus. There should be absolutely no hemolysis in the controls with healthy sera or physiological salt solution, or else an error must be suspected. Following is the proper positive test:—

Suspected serum, marked hemolysis.
Normal serum, no hemolysis.
Physiological salt solution, no hemolysis.
Distilled water, very marked hemolysis.
Known cancer serum, marked hemolysis.

Conclusions.—Several American workers have tried out this reaction upon a series of cases from

hospital wards with a view of verifying the claims of Kelling in regard to the reaction being specific. I am perhaps the only laboratory worker in the country who has put the method to use for the purpose of diagnosticating and differentiating inoperable abdominal tumors.

This communication has been prepared to answer a large number of inquiries from laboratory diagnosticians and other physicians concerning the technique and interpretation I have used. It seems to me that the method is a promising one and deserves further study, not so much by the research worker as by the diagnostician.

109 EAST COURT.

AUTOINTOXICATION FROM CHRONIC INTESTINAL STASIS, DUE TO HYPERTROPHY OF THE SPHINCTER ANI, SIMULATING APPENDICULAR COLIC.*

BY ARTHUR A. LANDSMAN, M.D.,

NEW YORK.

CLINICAL ASSISTANT DEPARTMENT RECTAL SURGERY, N. Y. POST GRADUATE MEDICAL SCHOOL AND HOSPITAL; DEPUTY SURGEON, RECTAL DISEASES, O.P.D., N. Y. HOSPITAL; ATTENDING PHYSICIAN, HOME DAUGHTERS OF JACOB.

THIS case derives its interest from the circumstance that the patient was ill for four weeks with subacute abdominal symptoms, which were attributed to appendicitis, for which operation was advised.

The patient, a woman, is 20 years old, married, has one child of 2 years; her family history need not detain us. Menstruation and urination normal, habits good, appetite poor, bowels regular up to one year ago. Since then it has become increasingly difficult for her to have a normal movement; the stools being small, hard, dry, and lumpy, accompanied by straining, necessitating enemata and physic, even then productive of but poor results at the expense of much abdominal distress. She has been accustomed to only one movement in nine days for the past year.

Four weeks before she presented herself for examination, her condition became markedly worse, with pain in the right lower abdominal quadrant, cramps occurring at frequent intervals, obstinate constipation, nausea, headache, dizziness, backache, radiating pains in the legs, cardiac palpitation, but no fever, chills, or vomiting. Examination of the abdomen showed some distention, diffuse tenderness on deep pressure over the right iliac fossa, and hyperesthesia of the skin over the right lower abdomen; there was no pain on the right side when pressure was made over the left, no pain when the fingers were suddenly withdrawn after deep palpation, no subjective disturbance in the abdomen when the thigh was flexed on the pelvis. Temperature 99°, pulse 76. Vaginal examination showed no evidence of tubal or ovarian disease. Digital exploration of the rectum disclosed a small, tightly-contracted, irritable anus, with a hard, thickened muscular band surrounding the anal canal, which permitted only with difficulty the introduction of the little finger. The rectum was distended with feces.

The signs elicited by abdominal palpation were suggestive of subacute appendicitis, but the previous history of the patient, the function of the bowel, and the condition of the stools, together with the physical findings obtained on examination of the anal canal, pointed to partial intestinal obstruction due to hypertrophy of the sphincter ani, with secondary toxemic manifestations. Hence it was thought advisable to relieve the condition at this point, by division of the sphincter muscle. Ths was done under quinine and urea hydrochloride anesthesia, the wound was drained, and the anal canal dilated with a No. 10 Wales bougie daily. The patient had a satisfactory movement on the day following her operation, unassisted, and a normal defecation every twenty-four hours since; her abdominal cramps and tenderness in the right iliac fossa disappeared with the establishment of normal bowel function, all subjective gastric disturbances ceased, and she feels better than she felt in a year.

No attempt is made to draw any general conclusions from one case, and it is simply reported as an interesting instance in which symptoms indicating a grave intra-abdominal condition were apparently due to an obstruction in the anal canal, and were promptly relieved when the obstruction was removed. The writer is well aware that this patient may quite possibly harbor an appendix in a latent state of inflammation, which may light up at some future time—that is a negative proposition which he is not disposed to argue; nevertheless, it will be admitted that there appears to be a significant relation of cause and effect in the condition of this patient before and after the operation.

Two points deserve attention: (1) That toxemia from absorption of intestinal contents may produce symptoms which simulate appendicular colic; (2) That the cause of chronic constipation may be found in mechanical conditions of the rectum and anal canal, which are aggravated by physics and enemata, but yield at once to simple operative measures, which may be undertaken under local anesthesia.

748 FIFTH STREET.

Medicolegal Notes.

X-ray Photographs as Evidence.—In an action for alleged malpractice in the treatment of a fractured wrist, expert medical witnesses called by the defendant testified that *x*-ray plates of the wrist offered in evidence for the plaintiff as showing an indentation showed the epiphyseal line. In rebuttal the plaintiff showed by a medical witness that on the preceding day the latter was requested by the plaintiff's attorneys to take an *x*-ray photograph of a pair of normal wrists and that he had done so. The plaintiff then offered the *x*-ray photograph so taken for the purpose: (1) Of rebutting the defendant's evidence that the radii shown by the *x*-ray plates in evidence were normal; (2) of rebutting the testimony given in defense that the epiphyseal line appeared on the *x*-ray plates (in the case) of the radii, and (3) of showing normal radii, the condition and appearance of normal radii, to rebut the testimony of the defendant's witnesses that the radii shown by the *x*-ray plates in evidence showed normal conditions. It was held that this evidence was properly excluded for two reasons, if not more: (a) The receipt of the photograph offered would have raised many collateral and immaterial issues, such as whether the wrists there represented were in fact normal, whether the age of the person whose wrists were shown was such as to make his or her wrists fairly and reasonably similar to the normal wrists of the plaintiff, whether the photograph was taken in a manner fairly to represent the wrists of the person in all respects material to the purpose for which it was offered, etc. On all the questions so raised evidence would have been admissible, and thereby numerous immaterial collateral issues would follow bearing no relevancy to any question before the trial court. (b) The *x*-ray photograph offered was the result of an experiment entirely outside the case. The photograph was held to be admissible only in the discretion of the trial court, and the wisdom of its exclusion was obvious from the immaterial and collateral issues likely to arise if it were admitted.—Davis vs. Dunn, Vermont Supreme Court, 98 Atl. 81.

THE MEDICAL ASPECT OF UNIVERSAL MILITARY EDUCATION.

IN all the great amount of discussion which has been going on about "preparedness" and compulsory military service or education, the arguments have largely centered around the legality of the procedure, its military necessity or advisability, and the possibility of the development of a militaristic party which would endeavor to force the country into war. Advantages which would accrue to the individual in the way of physical and mental development have been mentioned but not, we think, with sufficient emphasis.

While this country may excel in a competition of trained athletes or in certain kinds of mental ingenuity or shrewdness it is certain that the average man is far from being a picture of perfect physical development, and the lack of self-control and the extreme contempt for the law of the American have become proverbial. A casual inspection of the crowds on the streets of any one of our large cities will reveal pale, undernourished, and poorly developed youths and pasty, flabby men in large numbers, and will convince the open-minded observer of the desirability for the individual of some form of regular physical training. That the country-bred, moreover, are not greatly superior to those brought up in the city has been the experience of most military men who have had occasion to handle large numbers of troops.

In addition to this physical handicap the country is cursed with the presence of a very large group who, confusing liberty and license, confess allegiance to no constituted authority. These individuals demand from society every protection and the opportunity for material gain but deny the right of that society to exact any return. It is particularly in respect to these points that Dr. Lucien Howe develops his discussion in his recent book on Universal Military Education and Service.* He points out the position of the United States in world politics and our need for adequate preparation, and outlines briefly the Swiss and Australian systems and their applicability to this country.

The many advantages of universal military education to the nation are so evident as to need little discussion and he devotes most of his attention to the development of his chief argument, the advantages of such education to the individual. Education should include the development of the pupil in at least four different directions—health, knowledge, character, and efficiency. He points out that of twenty million pupils in this country about three-fourths have physical defects sufficiently grave to require attention and seriously to threaten health. Partly as a result of this poor start the standard of health of the average American is so low that over 50 per cent. of the applicants for the Army and Navy were rejected for physical disabilities in 1914 and in the following year less than 10 per cent. of the applicants for the Marine Corps were found to be physically fit.

Most certainly any system of military training would necessarily include gymnastic exercises and these regularly performed and accompanied by the regular routine physical examinations would inevitably rapidly raise the standard of physical health of our youth. In the matter of knowledge America does not rank so low as she does in military strength yet there is still room for improvement. In all countries the percentage of illiterates is much less in the army than in the civilian population and in Germany, the most militaristic nation of our time, there is but one illiterate for every 385 in the continental United States.

In its effects on character and efficiency a military training would have no less striking and important results. The lack of deference shown by the American boy to his elders is notorious and parallels his lack of self-restraint and self-sacrifice, qualities out of which character is developed. As logical consequences of our slackness in early training America stands high among the nations in intemperance, divorce, disobedience to law, and crime. The most sure way of correcting these fundamental faults in our youth is shown to be some form of military discipline. Universal military training would also provide trade instruction for the youth and thus increase his efficiency as a unit in the country's productive strength. The girl also would receive her share in instruction and would be better prepared to share in governmental responsibilities and in the education of the young. The attitude of the so-called "pacifists" and their apparent number afford strong support to the disgraceful accusation that many Americans rank low in loyalty and in readiness to sacrifice personal interest to the good of the country.

The one great lesson taught by military service is the one great lesson most needed by the citizens of this country: *obedience*. The attitude of the "anti-preparedness" adherents is strongly remindful of that of the antivivisectionists who are always perfectly ready to receive the benefit of any medical progress which is founded directly on animal experimentation but who, from either a silly sentimentality or dense ignorance, deny the right of the profession to use the means by which such knowledge is obtained. It is a sad commentary on the condition of things in the United States that such a book as that of Howe's should be necessary. It is a hopeful sign for the future that such a book has been produced.

*Universal Military Education and Service; the Swiss System for the United States, by Lucien Howe, F.R.S.M. Price, $1 net. G. P. Putnam's Sons. New York and London. 1916.

THE CARE OF RURAL SCHOOL CHILDREN.

THERE is little doubt that in every country physical efficiency is rare, this is to say, that in the large majority of individuals there exist defects which subtract considerably from the ideal of perfection. Of course, no one is physically perfect and most of us are far from that state. That physical imperfections abound is continually being demonstrated by the rejections for army service in all countries. Before the outbreak of war in Europe the rejections in Great Britain were numerous and in this country a similar state of affairs prevails. Dr. Taliaferro Clark, surgeon, U. S. Public Health Service, writing in Public Health Reports, Oct. 6, 1916, states that an officer connected with the recruiting station of the U. S. Marine Corps, New York City, has been quoted by George J. Fisher in "Physical Preparedness" to the effect that only 316 of 11,012 applicants for enlistment in this branch of the public service were up to the required physical standard.

The particular point, however, that Clark makes, is that it has been noted by observers in other countries that, in the case of volunteers for military service, rejections because of physical unfitness are in direct relation to the number of years spent in the school. The writer therefore, seems inclined to think that there may be some truth in the hypothesis that the schools may be responsible in a measure for such lack of development. He further holds that this view is all the more evident when it is recalled that the greatest number of rejections for enlistment on account of physical defects were due to abnormalities of physical development, defective vision and hearing, heart disease, faulty teeth, and postural defects. These defects are to a great extent preventable, or at least controllable, depending upon their prompt recognition during childhood, the period in which so many of them have their origin.

In discussing the condition of school children in one county in Indiana, in which investigations were undertaken by the Public Health Service with regard to physical averages, it is pointed out that, compared with the records of children in most urban centers as tabulated in "A Manual of Diseases of Infants and Children," by John Ruhräh, the boys of this county were below the average height from the age of 6 to 17. The girls were under mean height from the age of 12 to 17. The deficiency ranged from 0.7 to 2.3 per cent. among boys and from 0.2 to 2.8 per cent. among girls. The deficiency of weight from the age of 7 to 15 varied from 0.2 to 5.9 per cent. in boys, and from the age of 7 to 16 in girls 0.6 to 8.9 per cent. Unsuitable food was found to be the chief cause of this backward physical development. Moreover, no adequate facilities for play were provided and no systematic physical exercises were practised in any of the rural schools of this county.

Ear troubles, impaired vision, and defective teeth were found to be very prevalent. With regard to impaired vision faulty illumination is held to be largely responsible for the condition and in addition to this, a number of rural school children were badly in need of glasses and had never been refracted. It goes without saying, that the rural school child is greatly in need of instruction in the care of the teeth and in need of adequate dental service. It was shown that no fewer than 49.3 per cent. of the children of this county had defective teeth and only 16.9 per cent. had dental care. Furthermore, 14.4 per cent. of these children never used a toothbrush, 58.2 per cent. used one occasionally and only 27.4 per cent. used one daily.

Sufficient evidence has been already gathered to indicate that the school is a factor in the spread of communicable diseases in rural communities, due largely to the fact that the children of different families are rarely in intimate contact except at school. The question then arises how are all these conditions to be remedied and according to Clark the answer is: (1) By abolishing school districts and establishing a country unit of school administration; (2) by establishing an efficient system of health supervision of school children; (3) by consolidating rural schools.

When it is borne in mind that rural school children in this country constitute 60.7 per cent. of the total school enrollment of the country, the vast importance of properly caring for their health and of endeavoring so to bring them up that both mentally and physically they may be able thoroughly to fulfill their duties and responsibilities is too obvious to require elaboration. In order to attain this object their health supervision should be more strict by far than it is at present. This Indiana county presumably offers a fair example of what school children are in an agricultural district and the investigations of the Public Health Service plainly show that reforms should be promptly introduced if a decent standard of health among the school children of the country is to be hoped for. Children of a school age spend more of their waking day at school than at home and it behooves the authorities to insist that every effort should be made to establish and maintain their physical and mental health.

THE DIAGNOSIS OF RENAL TUBERCULOSIS.

GUINEA-PIG inoculation has long been accepted as the most reliable method for the diagnosis of tuberculosis, not only of the kidney, but also in other parts of the body, such as the pleura, peritoneum, etc. The method has the great advantage of being almost absolutely sure in its results, but has the disadvantage of requiring a long time before the results of the test can be obtained. Several attempts have been made to shorten this time without weakening the value of the test. The French advocated injecting the material into the lactating breast, which was said to be especially susceptible to infection with the tubercle bacillus. Three years ago Keene and Laird injected the material into the thigh and traumatised the inguinal glands, both before and after the injection. They claimed to be able to recognize tuberculosis of the traumatized glands on microscopical examination ten days after the injection. But lactating pigs are not always at hand, and traumatising inguinal nodes of thirty or forty pigs every day, as would be demanded in a large hospital laboratory, would use up a deal of time.

To shorten time and assure results, Morton has recommended the use of the *x*-ray. He bases his work on the demonstration by Murphy and Ellis that white mice which have been exposed to *x*-rays are made markedly more susceptible to bovine tuberculosis than normal animals. This increased susceptibility was apparently related to a destruction of the lymphoid tissue. Morton first ascertained (*Jour. Exper. Med.*, 1916, xxiv, 419) that guinea-pigs could tolerate a large amount of *x*-rays without apparent injury to their health, and that one massive dose would reduce the total white cell count by about one-half. This reduction affected mainly the lymphoid cells and was apparent for a period of more than one week. His method was to radiate the animal, at the time of the inoculation, for ten minutes with a Coolidge tube at 12 inches, with 5 milliamperes and 8½ inches of spark. From one to two cubic centimeters of urine was injected intraperitoneally and the animals were killed and examined after ten days. His results were excellent in a small series of animals. He lost but one out of ten from a mixed streptococcus infection, and all the control animals gave negative results.

The only objection to the method is that susceptibility is increased to other infections beside the tuberculous, and in those cases in which a mixed infection is present it would probably be advisable to inoculate two animals, one treated and one not, so as to avoid the loss of the animal. The method could, of course, be extended for use with fluid from the chest, abdomen, and spinal canal, and if continued favorable results were obtained, would effect great saving, not only in the feeding of animals, but also in the stay of the patients in the hospital.

Intraspinal Injections of Tuberculin in Meningeal Tuberculosis.

The high mortality of tuberculous meningitis is warrant enough for any effort to reduce it. The number of recoveries from this affection is very small; some years ago the few alleged recoveries were discredited, the diagnoses having been purely clinical, but with the introduction of lumbar puncture the possibility of cure was demonstrated. The intraspinal injection of tuberculin as a form of local therapy is of quite recent date, Bacigalupo, one of the first to test the remedy, having cured two patients, one with three and the other with two injections. Laforo, in *La Pediatria Española*, says he failed to cure two cases treated, but obtained in one a markedly favorable response to the remedy. A girl aged 9, with evidences of the disease, received lumbar puncture without incidental relief. The fluid was clear, and came out without much pressure. There was an intense lymphocytosis. An injection of tuberculin (Koch's old tuberculin) was made. The symptoms remained severe for some hours. A second puncture gave exit to much fluid, under high pressure, with prompt improvement throughout, the temperature becoming normal. The following day another decompressive puncture relieved the symptoms, which had reappeared. The child, however, slowly succumbed to the disease. The second child was 18 months old, and had been ill 20 days when the first puncture was made. Withdrawal of 10 c.c. of fluid gave some relief. An injection of tuberculin caused a slight reaction and was followed by striking amelioration. For two days recovery seemed to be taking place, the child beginning to take nourishment with avidity. It was thought best to make another puncture and mix the fluid with tuberculin. An intense reaction followed, with headache, vomiting, strabismus, convulsions, and death two days later. The treatment went wrong because the puncture was mixed with blood, which clotted, and prevented admixture with tuberculin. In his next attempt the author, if he can obtain a clear punctate, will proceed to mix it with tuberculin, thereby securing a physiological serum in imitation of the Swift-Ellis salvarsanized serum. A solution of tuberculin in physiological serum, 1 to 100, is used, and from this is formed another of 1 to 10,000. Of this 1 c.c. is mixed with the punctate (10 or 15 c.c.), and the whole is slowly thrown into the spinal canal. In the favorable results on record, headache, vomiting, etc., disappear.

The Fourth Disease in Italy.

The Italian literature of the so-called Filatow-Dukes disease appears to be very light, for in a representative bibliography of important reference works we see nothing in that language. In fact, we obtain the impression that the disease is not cumulative in southern Europe. However, Donetti of Lucca reports 15 cases in *La Riforma Medica* for August 21, and his conclusions evidently concur with those of the classic writers on the subject. It is a clinical entity, a children's disease of the general infectious type, with an incubation period of from two to eight days in most cases. It begins as an angina, simple or follicular, with reaction in the proper lymphnodes. Fever is due to the anginous component. The eruption comes out during a period of four or five days, beginning about forty-eight hours after the first evidence of disease. At first there is a general rash, but small papules soon replace it, and appear to characterize the disease. The fever subsides long before the completion of the outbreak. There is a rapid period of desquamation, the epidermis of the digits coming away in flakes. Itching is usually present. Complications may be renal or pulmonary. Enlarged cervical and submaxillary lymphnodes may persist for a long time. Not infrequently the general health suffers. The incidence is epidemic throughout.

A Cynic's View of Syphilis.

Nothing is safe from the ridicule of a witty Frenchman, and Voltaire was the wittiest of them all. Naturally, the great problems of life, death, and disease were, with him, the material from which epigrams could be made. In those days, syphilis held sway untroubled by premonitions of the days of salvarsan, and its ravages were frightful. Thus, in *Candide*, the author tells of the horrible havoc played with the features of Pangloss by the disease, and its failure to cure his optimism. He makes his characters tell of the prevalence of lues among the soldiers, two-thirds of whom, he says, were affected. By means of the military this affliction was carried into country villages where, hitherto, love-making had been as free and unrestrained as among the birds of the air. To combat its encroachments, mercury was used lavishly, until the treatment became only the exchange of one form of poisoning for another. The experience of the

present war is again illustrative of the way in which the disease is spread by soldiers, showing that often the life of the soldier, whatever may be its value in inculcating habits of discipline while he is on duty, tends to relaxation and license in his leisure moments.

A Discussion on Health Insurance.

In writing on health insurance a few weeks ago, we expressed the hope that every medical society in the State would set aside at least one evening for the discussion of this important subject, so that when the Legislature takes up the matter, as it must at the coming session, the medical profession may be informed regarding it and be able to cooperate intelligently with the lawmakers in formulating a fair and workable measure. We are therefore glad to learn that a public meeting has been called by the Committee on Medical Economics of the Medical Society of the State of New York, to be held at the Academy of Medicine on Thursday evening, November 23, to discuss the entire subject of compulsory health insurance. The topics announced are the following: "Introductory Remarks," by the Chairman, Dr. Samuel J. Kopetzky; "Relations to Preventive Medicine," by B. S. Warren, M.D., U. S. Public Health Service; "The Labor Man's Point of View," by Mr. Hugh Frayne, American Federation of Labor, National Civic Federation; "The General Medical Practitioner's Point of View," by Eden V. Delphey, M.D.; and "The Advantages of Compulsory Health Insurance," by Mr. Miles M. Dawson, Insurance Expert. Now that the State Society has set the example, doubtless the county societies will follow suit, and then when the measure is introduced at Albany it will more likely be in the form of a wise and just law and one that will be acceptable to physicians and the public alike.

News of the Week

Foundation of a Medical School in the University of Chicago.—The General Education Board and the Rockefeller Foundation have announced the appropriation of $2,000,000 for the establishment of a medical department in the University of Chicago. It is understood that the university will set aside at least an equal sum for the same purpose, will give a site on the Midway, valued at $500,000, and will raise a further sum of $3,300,000, and that, in addition, the present plant and equipment of the Presbyterian Hospital, Chicago, valued at $3,000,000, will be placed under the control of the medical department of the university. At present, the University of Chicago has no medical school of its own, though it has an agreement with the Rush Medical College. The new school, however, will be entirely independent of the latter, which it is expected will go out of existence as soon as the new department is ready. It will thus be possible to organize the medical school from the beginning along the most recent developments in medical education, and it is planned to include in the Faculty and teaching force only full time men, as regards both laboratory workers and clinical teachers. Laboratory buildings will be provided and also a university hospital. The latter, under complete control of the university, with laboratories and an out-patient department, will offer ample facilities for clinical teaching. The restriction of the members of the teaching force to full-time workers is in line with action already taken at Johns Hopkins Medical School and at the Medical Department of Washington University, St. Louis. The new school is expected to provide accommodations for 300 students, all of whom will be required to have an academic degree before entering, and it will also have facilities for postgraduate work.

Prevention and Relief of Heart Disease.—The Board of Governors of the Committee for the Prevention and Relief of Heart Disease has developed plans for an active campaign to arouse public interest in the important problems with which it is dealing, and has placed the work in the hands of special committees dealing with various phases of the problem. The Committee on Relief has outlined a program which covers, first, occupation for cardiacs, both children and adults; second, the establishment of classes for cardiacs, when possible in connection with hospitals, with duties divided into medical and social; third, the obtaining of more opportunities for cardiac patients in convalescent institutions; and, fourth, provision for permanent institutional care. The committee's program is of especial interest in connection with the plans now being laid for the after care of poliomyelitis patients, the two problems presenting many of the same aspects, though the care of cardiac patients is really the more important of the two. It is estimated that there are in the city about 20,000 children alone suffering from heart disease and requiring systematic care. In a number of ways the two groups need similar provision for relief; both should be under constant social and medical supervision; the members of both should be fitted for occupations suited to their infirmity; some of the children in both groups need to be taken to school in conveyances. It would seem, therefore, that a way might be found to coordinate the work of existing agencies to the fullest extent. The committee on relief appeals for funds to carry on its work.

Gifts to Charities.—By the will of the late Mrs. Caroline A. Wilson of New York, the Presbyterian Hospital of this city receives a bequest of $25,000.

New York Physicians' Association.—At a meeting of this Association to be held Thursday, Nov. 23, 1916, at 8.30 P. M., Prof. Alfred Stengel of the University of Pennsylvania will present a communication on "Practical Differentiation Between the Various Types of Chronic Nephritis."

St. Joseph's Hospital, St. Francis' Hospital, the Home for the Blind, and St. Rose's Home for Incurable Cancer, New York, receive bequests of $500 each by the will of the late Catherine E. Brown of Brooklyn.

A bequest of $15,000 is made to the House of Mercy Hospital, Pittsfield, Mass., by the will of the late Mrs. Louise F. Crane of Lenox, Mass.

Personals.—Dr. William T. Councilman of Harvard University and Dr. Robert A. Lambert of Columbia University will accompany the expedition headed by Dr. Alexander Hamilton Rice, which will sail shortly for South America. The members of the expedition will make a topographical survey of portions of the Amazon Valley and a study of the diseases of natives in those regions.

New Medical Society.—At a convention held in Pensacola, Fla., on October 27, the West Florida and South Alabama Medical Society was formed, the following officers being elected: *President*, Dr. Louis de M. Blocker, Pensacola; *First Vice-President*, Dr. M. S. Davie, Dothan, Ala.; *Second Vice-President*, Dr. E. Porter Webb, Laurelhill, Fla.; *Secretary-Treasurer*, Dr. Fritz A. Brink, Pensacola.

Obituary Notes.—Dr. William Judkins Conklin of Dayton, Ohio, a graduate of the Medical College of Ohio, Cincinnati, in 1868, and a member of the Ohio State Medical Association and the Montgomery County Medical Society, died at his home on October 31, after an illness of several months, aged 72 years. Dr. Conklin was formerly a member of the Starling Medical College, Columbus, Ohio, and since his removal to Dayton had been active in many ways in the city's life, serving in the Board of Education and in the Library Board, of which he was for eighteen years president.

Dr. Frank S. Stirling of Lewiston, Idaho, a graduate of Cooper Medical College, San Francisco, in 1864, and a member of the Medical Society of the State of California and the Nez Perce County Medical Society, died on October 15. Dr. Stirling was formerly physician and surgeon for the Pacific Mail Company, and served as surgeon in the United States Army during the Modoc war.

Dr. Clinton E. Sapp of South Omaha, Neb., a graduate of the Medical College of Ohio, Cincinnati, in 1875, died at the south Omaha Hospital on October 12, aged 64 years.

Dr. James Bennett Gould of Minneapolis, Minn., a graduate of Jefferson Medical College of Philadelphia, in 1886, and a member of the American Medical Association, the Minnesota State Medical Association and the Hennepin County Medical Society, died from apoplexy on October 17, aged 56 years.

Dr. John P. Moore of Astoria, L. I., a graduate of the University of Vermont, College of Medicine, Burlington, in 1894, physician to St. John's Hospital, Brooklyn, and a member of the Associated Physicians of Long Island, and the Greater New York Medical Association, died on October 24, aged 50 years.

Dr. Frank Duane Maine of Springfield, Mass., a graduate of New York Homeopathic Medical College and Flower Hospital, New York, in 1872, died suddenly on October 29, aged 77 years. Dr. Maine was a veteran of the Civil War.

Dr. Franklin S. Jewett of Providence, R. I., a graduate of Hahnemann Medical College and Hospital of Philadelphia in 1894, died at his home on October 24, after a long illness, aged 59 years.

Dr. Edward Sydney McKee of Cincinnati, Ohio, a graduate of the Medical College of Ohio, Cincinnati, in 1881, and a member of the Ohio State Medical Association, the Hamilton County Medical Society, and the Cincinnati Obstetrical Society, died from malarial fever at Quito, Ecuador, on October 20, aged 58 years.

Dr. Jacob M. Dennis of Hopkinsville, Ky., a graduate of Jefferson Medical College of Philadelphia in 1860, died from paralysis recently, at the home of his son, aged 82 years.

Dr. Charles William Penn Brock of Richmond, Va., a graduate of the Medical College of Virginia, Richmond, in 1859, and a member of the Medical Society of Virginia and the Henrico County Medical Society, died at his home on October 19, aged 80 years. Dr. Brock was a veteran of the Confederate Army.

Dr. D. L. Howell of Big Rock, Va., a graduate of the Medical Department of Vanderbilt University, Nashville, in 1877, died at his home recently, aged 59 years.

Dr. James M. Coyle of Nashville, Tenn., a graduate of the Medical Department of the University of Nashville, died at his home on October 21, aged 66 years.

Correspondence.

CALCIUM DEFICIENCY IN NEPHRITIS.

To the Editor of the Medical Record:

Sir:—To the question, "Is calcium deficiency incidental or an essential factor in nephritis?" I can now answer positively in the affirmative. The proof is to be found in an examination of the blood, and, of course, this puts the treatment of the disease upon an entirely new basis. Thus, it will now be possible to determine with exactness the defective metabolism in this disorder, since it is not a difficult task for a chemist to make this test. This information was brought to my attention by Dr. P. B. Hawk, professor of physiological chemistry in Jefferson Medical College, who has been studying calcium metabolism during the past few years, and he has advised me that the same holds true in respect to diabetes mellitus. Such being the case, it follows that rheumatism, so-called neurasthenia, and a long list of chronic ailments fall into the same category, confirming my clinical evidence relating to the deleterious effects of acid excess.

John Aulde, M.D.

1305 Arch Street, Philadelphia.

A DISCLAIMER.

To the Editor of the Medical Record:

Sir:—During the progress of the Anderson trial in Brooklyn I was reported in the newspapers as having said that the case was not one of anterior poliomyelitis. I endeavored in vain to obtain a retraction of this statement both from the reporters and the editors responsible for it. I would like to have published the statement that at no time did I give to anyone, not even to counsel, my opinion of the case until it was given to the court while I was on the stand. John P. Davin, M.D.

117 West Seventy-sixth Street, New York.

OUR LONDON LETTER

(From Our Regular Correspondent.)

ROYAL COLLEGE OF PHYSICIANS—HARVEIAN ORATION—DONATION OF £10,000 FOR RESEARCH—CAN VENEREAL DISEASES BE STAMPED OUT?

London, October 21, 1916.

The Harveian oration at the Royal College of Physicians was delivered on Wednesday by Sir Thomas Barlow. The chair was occupied by Dr. Frederic Taylor, president, and there was a good attendance of the Fellows. Among the guests was the Archbishop of Canterbury. The orator gave a summary of the life of Harvey and pointed out that he was carrying on a tradition that had arisen from that great physician, who was one of the principal benefactors as well as ornaments of the college. Harvey's discovery of the circulation of the blood was made during a period of great revival of learning, when the creation and dissemination of England's finest literature was in progress. Astrology was as widely accepted for science as astronomy, but physics was not then a science at all. Chemistry was dominated by unreliable hypotheses or mere guesses. Harvey's *magnum opus* was for a long while during his lifetime linked with the College of Physicians. For 12 years he expounded his doctrine and met with only one adverse critic among the Fellows. He was not only a *doctor*

medicinæ but a *doctor medicorum*, and in paying homage to him to-day the Fellows were only reviving the great respect and homage that had been paid to him by the college during his lifetime. He several times gave expression to his belief in God and the Christian faith. He displayed intense love for his family and friends, and willingness to take trouble on behalf of the students of his time. It behooved Fellows to seek out the secrets of nature as he had done and to continue in mutual love and admiration among themselves.

The orator announced that in June last the sum of £10,000 in $2\frac{1}{2}$ per cent. annuities had been offered by Mrs. Eliza Streatfield for the purposes of endowment and research. The gift had been gratefully accepted by the college.

A morning paper has been discussing the possibility of stamping out venereal diseases, thinking that the record of the president of the local Government Board in respect to rabies a reason for expecting from him that active administrative action and dogged perseverance which he displayed in that case. As hydrophobia is produced in man only by direct contagion from animals—most frequently from the bite of a rabid dog, though occasionally by handling contaminated material—so syphilis and gonorrhea are spread only by inoculation of their specific poisons from person to person. That is the rule, but exceptionally the infection may be carried by contaminated articles, as, for instance, a pipe or a towel. Hydrophobia is not a common disease in England—never has been. The highest number of deaths from it in any one year since 1880 was 60—in 1885. Since 1902 no death has been recorded from this disease, if we except two doubtfully ascribed to it in 1910 and 1911. This result has been attained by means of the regulations enforced by Mr. Walter Long, who prevented the landing in this country of dogs from other countries until after a period of quarantine exceeding the period of incubation of rabies, and who in spite of the opposition of many dog owners, especially women, insisted on the continuance of his muzzling order until not a single case of rabies remained in the country. This remarkable success may encourage the hope of similar results in other directions. But the detention of travelers until they can prove themselves free from venereal disease is obviously not practicable. Yet if all the forces of prevention and treatment can be brought to bear, some success in controlling the spread may be attained. Among the chief measures requiring attention are those for securing the early recognition of these diseases and their treatment under the best modern conditions. It has been suggested that confidential notification to the medical officer of health might be tried, but even if possible the practical drawbacks to this would prevent its success and the attempt to introduce it would drive many patients into the arms of the quacks. Early treatment is so important that it is of the first importance to get patients to submit themselves to their attendant on the first symptom, and to carry on his treatment until he pronounces them recovered, and still further to watch for and refer to him every suspicious appearance of a return. It is by persons who have neglected treatment that these diseases are chiefly spread, and it is persons who do not recognize the significance of early and mild symptoms who later fall victims to urinary diseases, or to paralysis, or insanity, or who are responsible for bringing into the world infected children.

CANADIAN LETTER.

(From our Special Correspondent)

CANADIAN HOSPITALS COMMISSION—THE CONVALESCENT ARMY HOSPITAL IN COLLEGE STREET, TORONTO—OPENING OF A MILITARY HOSPITAL IN TORONTO—REORGANIZATION OF CANADIAN ARMY MEDICAL SERVICE—PROHIBITION IN ONTARIO—ANNUAL MEETING OF THE CANADIAN ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS—ABSENCE OF SMALLPOX IN ONTARIO AND INCREASE OF POLIOMYELITIS—DR. JOHN FERGUSON MADE PRESIDENT OF TORONTO ACADEMY OF MEDICINE—OBITUARY.

TORONTO, Oct. 18, 1916.

THE Canadian Hospitals Commission was formed by order-in-Council, dated June 30, 1915, for the purpose of providing convalescent homes and medical treatment for returned invalided and wounded members of the Canadian Expeditionary Force. It was decided later that the powers of the commission should be extended to cover the matter of the vocational re-education of those who through their disability might be unable to follow their previous occupations; also that the necessary machinery in the form of Provincial Commissions and local committees should be installed in order to provide employment, not only for disabled men, but at the close of the war, for the able-bodied men as well. As mentioned in a previous letter there is a large number of these convalescent hospitals and homes in various parts of Canada and the large one on College Street, Toronto, was referred to particularly and it was stated that further details would be given concerning it. The hospital is situated in a large old-fashioned roomy building in a central part of the city, placed in spacious grounds. It will accommodate more than one hundred inmates and when I paid a visit the other day appeared to be filled almost to its capacity.

The majority of the men were suffering from injuries of different kinds received at the front. A few were recovering or partially recovering from the effects of gas poisoning. A goodly proportion were suffering from shock to the nervous system in addition to injuries. The most depressed men among the inmates (as a rule, they were in excellent spirits) were those who had been poisoned by gas. It appears to have a peculiarly lowering effect and, of course, exerts the greater part of its evil effects upon the respiratory organs.

The equipment of this hospital for providing the patients with the means of mechanical treatment is singularly complete. All the apparatus was given privately and it is largely due to the efforts of Mr. F. Davies that so splendid an equipment was got together. Hydrotherapy is practised considerably by the agency of circular douches, needle douches, and rain douches for the relief of nerve troubles and rheumatism. Continuous leg baths are employed for treatment of stiffness of the joints and similar methods are used for the treatment of stiffness of the arms. Full bath bodily treatment is utilized for nervous cases and light mental cases. There is an electrical limb baker for joint stiffness; also an electric cabinet for the treatment of neuralgia, rheumatism, and neuritis; an electrical cradle for applying heat locally to feet, hands, or, in fact, to any part of the body where such treatment is thought to be required; an electrical wall plate by which faradic and galvanic currents in all forms can be applied; high frequency cabinet with full electrodes; a lamp to be used for the sun ray treat-

ment, and lastly a complete equipment of Zander apparatus for rotation and resistant movements. It goes without saying that massage is largely used in connection with one or another of the hydrotherapeutic electrical or mechanical modes of treatment. It remains to be said that the results, on the whole, have been eminently satisfactory and that many men who without these forms of therapeutic aid might have been seriously crippled are relatively sound and supple in limb.

Another military hospital was opened in Toronto a few days ago. The old Knox College, a fine spacious building on College Street, has been provided by the Ontario Provincial Government for the treatment and care of returned wounded Canadian soldiers. Numerous organizations, including the Ladies' Voluntary Aid Society of Toronto, the Masonic Order, the Orange Order, the St. Andrew's Society, the Daughters of the Empire, provided furnishings and comforts for the soldiers. At the opening ceremony Sir James Longheed, chairman of the Military Hospitals Commission, in his speech gave a detailed account of what the Government was doing and prepared to do for the returned soldier. He pointed out that in Canada 6000 men had already passed through the convalescent homes. These figures give some idea of the work being carried on and also of the work which would have to be done before the war is over.

In my former letter I called attention to the fact that Col. Herbert Bruce of Toronto, who has been appointed Inspector General of the Oversea Canadian hospitals, had criticised some features of the existing system of the Canadian Hospitals in Great Britain. The main stumbling block to Colonel Bruce and to the committee composed of several of the leading army medical corps officers from Canada to assist him in his investigations, was the mixing of the Canadian wounded and the other British wounded. Colonel Bruce and the committee have given it as their opinion that the Canadian wounded should be segregated in Canadian hospitals. Sir Sam Hughes, the Canadian Minister of Militia, is said to be in accord with these views. It is stated that in the report submitted by Colonel Bruce a complete reorganization of the Canadian Medical Service is recommended, with the suggestion that the medical arrangements in Canada, in Great Britain and overseas be co-ordinated. Among other recommendations are that Canadian casualties be as far as is possible treated in Canadian hospitals and that the care of Canadian sick and wounded be the first duty of the Canadian Army Medical Corps, that the Canadian hospitals be concentrated and voluntary hospitals for Canadians be abolished, hospitals now conducted or equipped by the Red Cross being taken over by the Medical Service for administration, that incapacitated Canadian soldiers be returned to Canada as soon as they are fit to travel, for further medical treatment and that the three Canadian hospitals now at Salonica be returned to England immediately if they can be spared by the Imperial authorities. Other recommendations affecting arrangements in Canada are made. Among these are, that immediate steps be taken to provide hospitals with 1000 beds each in Halifax, Montreal, Winnipeg, and Vancouver, with a smaller one in Ottawa, and that these provide accommodation for a limited number of officers; that for the purpose of assisting in the organization of these hospitals a number of Canadian medical officers who have had experience at the front be detailed for duty in Canada; that all ranks before leaving Canada be examined by an independent medical board, a number of these boards to be established in various parts of Canada, this to be done for the weeding out of the unfit; that no medical units be organized in Canada in future for oversea duties; that the officers of the Canadian Army Medical Corps in future be thoroughly trained at well-equipped depots to be established in Canada. It is understood that Colonel Bruce makes the statement that both in France and in England Canadian soldiers have been begging to be taken to Canadian hospitals and that no effective measures have been taken to bring this about, while Canadian medical officers who have gone to England at the sacrifice of their practise in order to care for Canadian soldiers, rarely have the opportunity for treating a Canadian patient. It is chiefly for this reason that the concentration of Canadian hospitals is suggested. It is believed that Colonel Bruce has been authorized by Sir Sam Hughes to carry out the reorganization of the Medical Service immediately according to the plan which he has proposed in his report.

It would be ill-becoming in a letter to a medical journal not to refer to prohibition in Ontario. It is now impossible to obtain alcohol in saloons or stores anywhere in this large province. The results of the enforced abstinence are good. The step is a radical one but is decidedly in the interests of health.

The fifteenth annual meeting of the Canadian Association for the Prevention of Tuberculosis was held in the Parliament Buildings, Quebec City, on Sept. 12 and 13. The meeting was successful from all points of view. Dr. Peter Bryce of Ottawa read an excellent paper entitled "Why Notification of Tuberculosis is Necessary." The following officers were elected: Lieutenant-Governor of Quebec, Sir Evariste Leblanc was elected as honorary vice-president. Hon. J. W. Daniels, M.D., of St. John, N. B., was re-elected president. Dr. Alfred Thompson of Yukon and Hon. R. Turner of Quebec were also made vice-presidents. Dr. George Porter of Toronto was re-elected secretary treasurer.

For the first time in more than twenty years the monthly health returns to the Ontario Board of Health contained not a single case of smallpox. A good deal of the credit for this very satisfactory state of affairs must be given to Dr. J. McCullough, the chief of the Provincial Board of Health, who has been ably assisted in his campaign against the disease by the health officers in all parts of the Province. But a few years ago the malady was one of the most serious as regards both virulence and prevalence in Ontario and it says much for the work of public health medical men that they have been able practically to extinguish the disease. Poliomyelitis, however, shows few signs of decreasing, the September returns reading 76 cases and 7 deaths or 32 cases more than in August. The records point to the fact that the cases are rather sporadic than epidemic in character, the 76 cases being scattered over eighteen counties.

Col. H. A. Bruce, who was president of the Toronto Academy of Medicine, has resigned, owing to the likelihood that he will be in Europe for a prolonged period. Dr. John Ferguson, vice-president and editor of the *Canada Lancet*, has been elected president, and Dr. D. J. Gibb Wishart, vice-president.

Capt. W. O. McCarthy, M.D., of the Second

Rhodesian Regiment, son of the late Dr. McCarthy of Barrie, Ontario, was killed in action on Aug. 22, in German East Africa, in his thirty-seventh year.

Drs. A. A. Macdonald, H. T. Machell and C. R. Sneath, all of Toronto, have each had a son killed recently in action.

Capt. Dougald B. Maclean, M.D., R.A.M.C., a graduate of University of Winnipeg of 1911, has been killed in action.

Progress of Medical Science.

1. Relation of the Deep Cul-De-Sac to Prolapse of the Rectum and Uterus, and to Rectocele. Daniel Fiske Jones.
2. The Effect of Alcohol on the Rate of Discharge from the Stomach. L. T. Wright.
3. Blood Transfusion in the Great War. William Reid Morrison.
4. Undescended Testicle in Children. C. G. Mixter.
5. The Mechanism of the Protection Afforded by the Drainage of Prostatics as a Preliminary to Operation. Hugh Cabot and E. Granville Crabtree.

2. The Effect of Alcohol on the Rate of Discharge from the Stomach.—L. T. Wright has used the method first devised by Cannon in conducting these experiments. The work was done in the Laboratory of Physiology in the Harvard Medical School and the procedure in part was as follows: Medium sized cats, deprived of food for twenty-four hours, were fastened to a holder and fed through a stomach tube attached to a syringe, 25 cc. of mushy potato to which had been added 5 grams of bismuth subcarbonate. This amount of food causes the stomach in most cats to cast about the same shadow. Peristalsis and the rate of discharge in these animals were normal. The consistency of the food was uniform —the potato was mashed fine and softened by water and also alcohol. After being fed the animal was immediately released. *X*-ray observations of the gastric and intestinal shadows were made at the end of a half hour, an hour, and thereafter hourly until four hours after the feeding, and aggregate lengths of the shadows in the successive records were utilized to indicate the rate of gastric discharge. Wright divided his experiments, feeding six cats with potato-bismuth mixture without the alcohol, and another set of cats with the potato-bismuth-alcohol mixture. In the experiments with alcohol the commercial 95 per cent. alcohol was employed, and also a 37 per cent. alcohol diluted with distilled water. This gave two sets of experiments with the alcohol mixtures—6 c.c. of 37 per cent. and 5 c.c. of 95 per cent. The weaker mixture produced no striking symptoms, while the stronger mixture rapidly produced extreme intoxication. In the three sets of observations made the results obtained, representing in centimeters the aggregate length of the food-masses in the small intestine at the times above indicated, were as follows: In the first or normal set without alcohol the average amount at the end of a half-hour was 14 cm., at the end of two hours 39.5 cm., and at the end of four hours 20 cm.; in the second set in which the weaker dilution of alcohol was used the average at the end of a half-hour was 21 cm., at the end of two hours 52.5 cm., and at the end of four hours 36 cm.; in the third set in which the 95 per cent. alcohol was used the average at the end of a half-hour was 2 cm., at the end of two hours 24 cm., and at the end of four hours 39.5 cm. The first two sets of experiments, including the normal feeding of potato-bismuth mixture, and the same mixture containing the weaker alcohol dilution show an increase of the food in the intestines at the end of a half-hour, and a maximal number of centimeters of food at the end of two hours; but the increase at the end of a half-hour is 50 per cent. higher in the second set where the weaker alcohol dilution was used than the average figure for normal conditions, and the percentage obtained was higher at the end of an hour. This relatively small amount of alcohol, therefore, has distinctly an accelerating effect on the rate of gastric discharge and produces a higher maximum than the normal. The gastric peristaltic waves were deep and vigorous, and in most cases at the end of three hours no residue remained in the stomach. Contrary to these results in the third set of experiments where the 95 per cent. alcohol was used there was a slow initial discharge and a gradual rise to a maximum at the end of three or four hours. When evident the peristaltic waves were shallow and feeble and in some of the animals there was present at the end of four hours a considerable amount of food. The more rapid expulsion of gastric contents when the weaker alcohol was used may have been due to both a more vigorous peristalsis and a more prompt acidulation of the contents produced by a stimulation of the secretion of gastric juice by the weaker alcohol; while the retardation of the output when the stronger alcohol was employed was due probably to effects on both peristalsis and secretion. The profound influence of the stronger alcohol on the central nervous system indicates that the nerves of the gastric wall and possibly the muscle fibres were similarly affected. On the basis of an acid control of the pylorus as well as on the assumption of an intoxication of the gastric neuromusculature Wright states that it is easy to understand how the stronger alcohol mixed with the food produced so marked a slowing of gastric discharge as shown by these experiments.

4. Undescended Testicle in Children.—C. G. Mixter states that in the past three years thirty operations have been performed for the relief of this malformation at the Children's Hospital, Boston. In seven cases the condition was bilateral, in nine the right, and in seven the left side was affected. In nineteen it lay within the inguinal canal, and in eight cases it was just outside the external inguinal ring. In two cases atrophy was noticed at the time of operation. In one the testicle was enlarged and thought to be tuberculous with an accompanying tuberculous peritonitis. The age at operation ranged from twenty months to twelve years. The late result of operation was ascertained in twenty-six cases —four cases failed to report. The two cases in which atrophy was noted at operation showed no improvement in the development of the testicle, although the organ remained in the scrotum. Atrophy occurred in eight cases following operation. The age at operation had no bearing on the occurrence of atrophy. The one factor present in every instance where atrophy occurred was an interference with the spermatic circulation at operation. Mixter outlines his technique of operation in which he endeavors as often as possible to avoid sacrificing the spermatic vessels. He supplies statistics and concludes that a plastic operation by which the undescended testicle is placed in the scrotum without impairment to the circulation will be followed by normal growth. Where partial resection of the spermatic vessels is necessary atrophy may or may not ensue, while complete section of the spermatic vessels has been invariably followed by atrophy in a given series of cases, the blood supply from the artery of the vas being insufficient to nourish the developing testicle; this operation should be resorted to in children only under exceptional circumstances.

5. The Mechanism of the Protection Afforded by the Drainage of Prostatics as a Preliminary to Operation.—Hugh Cabot and E. Granville Crabtree present a consideration of the production of immunity in these cases in which drainage before operation has been an

important factor in reducing the mortality. Drainage as a preliminary treatment is most essential in the class of cases with the largely over-distended bladder, sometimes stretched to the point of overflow, but in whom infection has not yet occurred. The extremes are represented by the over-distended uninfected bladder and the thoroughly infected but regularly emptied bladder enjoying a catheter life. The benefits accruing from drainage in these cases appear to be the result of two factors: 1. Relief of the so-called "back-pressure," with the equalization of the kidney circulation, and 2. Infection which is now generally regarded as a pyelonephritis. Phthalein test was employed for the purpose of studying the changes in kidney function. Three conditions in these cases operate to depress kidney function at substantially the same time, namely, decompression congestion, operation, and pyelonephritis. Drainage has had the effect in point of time of placing pyelonephritis second, and operation, if necessary, third. Cabot and Crabtree have especially studied the nature of the pyelonephritis—commonly called pyelitis—and its effect on function, and from their studies have concluded that this condition is practically always produced by the colon bacillus, and that it is an excretory type of infection in that the lesion occurs in the attempt by the kidney to get rid of colon bacilli circulating in the blood. Blood cultures in these patients with prostatic obstruction on constant drainage are positive for colon bacillus in a proportion of cases about equal to that occurring in typhoid fever, and positive cultures are much more likely to be obtained when the blood is taken at the onset of the attack, and negative when taken at a subsequent period. Both the bladder and the urethra may be sources of infection, and irritability of the prostate is often observed at the onset of kidney infection. Pyelonephritis in their opinion is the most important avoidable incident of the preliminary drainage in cases of prostatic obstruction, and decompression is rarely of first importance in its effect upon the kidney; but the infection deserves the most weighty consideration and the chief benefit resulting from preliminary drainage is the immunity to pyelonephritis as a complication of the operation, which immunity is conveyed by this condition resulting from drainage, giving the patient a security which it has not been possible to obtain in another way. For the past six months Cabot and Crabtree have been endeavoring to produce an artificial immunity in these cases by means of vaccination with tho colon bacillus, and they have been able in so far as agglutination can be regarded as a measure of immunity to produce it in their patients. If this infection can be established by the production of artificial immunity, a considerable advance will have been made toward eliminating an important factor in the mortality of operative procedures for the relief of prostatic obstruction.

7. **The Oral Administration of Adrenalin.**—Henry R. Harrower has collected in one paper the opinions of various medical men as to the efficacy of adrenalin when administered by mouth together with his own views, the consensus of opinion being that in suitable dosage of 1,000 solution a speedy and favorable action is obtained. If adrenalin is given by mouth and the stomach is evacuated ten minutes later, it is usually impossible to detect this substance by colorimetric chemical measures. According to the specified authorities it may be used as an analgesic remedy for gallstone and renal colic, as part of the treatment of severe infectious diseases in children producing increased blood pressure and an immediate response in the general mental and physical condition, while the pulse rate is reduced and diuresis favored; acute and chronic nephritis is benefited most decidedly in many cases by the administration of adrenalin by mouth. The active principle of the desiccated gland is naturally similar to that which is available in a pure state, and the favorable experiences with total adrenal gland therapy, by mouth, is additional proof that the position of those who have contended that the oral administration of adrenalin is useless, is fallacious.

9. **Tracheobronchitis Due to Nitric Acid Fumes.**—Chevalier Jackson reports a case of a pipe-fitter, previously in good health, who complained of burning in the throat following a two hours' exposure to nitric acid fumes. Half an hour after exposure his lips became blue and five hours later he fell, becoming unconscious for a few minutes. Then cough, difficulty in breathing, and blueness of lips and face were noticed. Fine râles were found all over both lungs anteriorly and posteriorly, while showers of fine crepitant râles were audible at end of inspiration. In left axilla and in front inspiration markedly increased. Whispered voice plus. By indirect laryngoscopy frothy mucopus could be seen bubbling up and down in the trachea, but there was no coughing effort to expel same and no glottic bechic placement. Bronchoscopy showed intense acute tracheitis and bronchitis; the trachea and bronchi showed frothy mucopurulent secretion, and on removing this patches of grayish furred mucosa with a surrounding areola of intensely engorged cyanotic mucosa were found. The patient was choked with his own secretions until he was apparently drowning. Tracheotomy was performed, and large quantities of the mucopus were continuously removed. The temperature on admission was 101.3° F., but never rose above 102°, and subsided to normal at the end of a week. Gentle swabbing was done through the wound, and at the end of the fourth day the patient could cough out the secretions through the cannula. Compound tincture of benzoin was vaporized from a croup kettle close to the cannula. Atropine and stimulants were given as needed The patient was discharged well at the end of three weeks.

11. **Autotherapy in Ivy Poisoning.**—Charles H. Duncan quotes from an article of his published in the *New York Medical Journal* for Dec. 14 and 21, 1912, under the title of Autotherapy, in which he says that disease may be said to be the proving of one or more toxins. Symptoms are the expression, or the language, of toxins. The cure of disease is brought about by placing the exact toxins that cause the symptoms in healthy tissues. He then goes on to state that this method of treating ivy poison is nothing more or less than treating the symptoms with the substance that caused them or an autotherapeutic procedure, a method long known and employed by the writer, as in other forms of anaphylaxis. In Fairmount Park, Philadelphia, a few years ago, and also in Bronx Park, it was the custom upon hiring park hands to instruct them to chew a few leaves of the poison ivy plant when clearing away the vines, as a preventive to the well known

cutaneous eruption. Homeopathic physicians have long employed this method of treating ivy poison, and considered the cures as homeopathic cures till the writer pointed out that it was not a similar remedy, but the exact or autotherapeutic remedy, for it treats the symptoms with the exact unmodified substance that caused them and not a substance that causes a similar set of symptoms. Their occasional failures may result from the use of the tincture of Rhus other than the one with which the patient was poisoned. The exact unmodified substance that caused the symptoms is employed as the curative remedy. This is the principle upon which autotherapy rests.

4. The Recent Epidemic of Grip.—Joseph A. Capps and A. M. Moody made a study of the epidemic of grip which swept over the United States last winter. Their observations were carried on in Chicago, but in close touch with the laboratories of the Departments of Health in all of the important cities. The epidemic began early in December, and while it had spent its force by the latter part of January, many cases developed long after. The chief complications were inflammation of the accessory sinuses of the head and bronchopneumonia, the latter being responsible for most of the fatalities. Capps and Moody found from a study of the blood that in the majority of patients leucocytosis was absent, although a temperature of from 1° to 3° above normal was the rule at the time of examination. They state that while physicians may agree on the existence of a grip epidemic, it is equally true that bacteriologists have failed to agree on the causative organism. The results of analyses made in the public laboratories in various cities of throat cultures showed the presence of the *Streptococcus viridans* and pneumococcus together with the hemolytic streptococcus in all cases tested in Chicago, while the influenza bacillus was found only twice. In New York streptococcus was found most frequently, accompanied by *Micrococcus catarrhalis*, with the influenza bacillus in nine cases. From a cultural standpoint the streptococcus deserves more serious consideration as the causative organism than the influenza bacillus. The work of Kruse, and more recently Foster, suggests the possibility of some ultramicroscopic germ as the cause of the disease. Capps and Moody ask if the influenza bacillus was responsible for earlier grip epidemics, and note that the streptococcus and pneumococcus were the two organisms most constantly described in the pandemic grip of 1889-1890, and that it was not until 1892 that Pfeiffer published his discovery of the influenza bacillus, and it is still unproved that this organism was a factor in the earlier pandemic. The theory that grip is contracted through personal contact seems to be borne out by practical evidence, and at present there is no evidence that food may be a medium of transmission. The writers suggest that, as we look back on this epidemic, it may well be asked what has been done to prevent its inception and its dissemination. Have any measures of defense been developed against this ancient foe? Not in any adequate measure. Nor is it possible to make any headway along preventive lines until the laboratory workers go out into the community and there obtain their material for study. Furthermore, there should be a better organization of team work, so that a group of men can attack the problem simultaneously from several directions and correlate their efforts.

5. Acidosis of Gastrointestinal Origin: A Preliminary Study Based on Thirty-four Cases.—Henry Dwight Chapin and Marshall Carleton Pease. (See MEDICAL RECORD, June 17, 1916, page 1117.)

8. A Further Note on the Diagnostic Value of Retrobulbar Neuritis in Expanding Lesions of the Frontal Lobes.—Foster Kennedy states that in the recognition of disease affecting the frontal lobes there is apt to be a misinterpretation of symptoms by even the most alert observers. He calls attention to a syndrome referable to the inferior frontal sinuses, the occurrence of a true retrobulbar neuritis, with the formation of a central scotoma and primary optic atrophy on the side of the lesion together with ipsolateral anosmia and papilledema in the opposite eye. He cites the case of a woman presenting all these conditions, who had undergone a decompression operation from which she recovered, but who a little later died. An examination of the brain revealed a ruptured aneurysm of the right internal carotid artery about the size of a small walnut and of a solid consistency, owing to contained fibrinous matter. This aneurysm caused marked pressure on the right optic nerve, just in front of the chiasma, and, to a lesser degree, on the left optic nerve also. Upward and to the right it had succeeded in compressing descending fibers from the right motor area with some deformation of the anterior part of the right caudate nucleus. The anterior horn of the right lateral ventricle was considerably larger than its fellow. The case presents two features: first, the remarkable rarity of aneurysms of a right internal carotid artery; and second, its symptomatology offers a very important clue to the diagnosis of expanding lesions in the subfrontal area. The diagnosis of aneurysm in this case cited was quite unsuspected during the patient's lifetime. Syphilis was entirely excluded, the cerebrospinal fluid was normal with the exception of an increased globulin content, which but tended to confirm belief in the presence of new growth. The signs given here were sufficient to indicate the exact situation of an expanding lesion within the skull cavity, and the recognition of this syndrome may elucidate diagnosis in certain obscure cases of frontal neoplasm and to separate a group of cases from the great generic class of toxic amblyopias.

9. Appendicitis in Children.—J. Coleman Motley as a result of his operative work during the last five years says that his chief object is to appeal to the general practitioner and through him to the parent, for a closer cooperation with the surgeons in an effort to give the child with a "belly ache" a better chance to live. Of 404 cases, 37 were in children with an operative mortality of 5.4 per cent. Of the 367 adult cases of appendicitis, there was also an operative mortality of two, or 0.54 per cent. The most constant symptom of

acute appendicitis in children is leucocytosis, which ranges between 9,000 to 34,000, with the polymorphonuclears between 72 and 92 per cent. The high mortality among children seems to be due to the fact that the early symptoms are not clear-cut and defined as in adults, and are to be considered atypical. This leads to a confusion in diagnosis and also to the association of dietary indiscretions as the chief cause of all abdominal pains in children. Early diagnosis and early operation are indicated. Motley considers purgation in cases of appendicitis in children as one of the chief causes of the frequency of perforative appendicitis, but he does approve of an enema of soapsuds for relief of either an overloaded bowel or the pain in appendicitis. He again begs for early diagnosis and operation as the only sure means of saving life.

12. **Studies of the Spinal Fluid During Iodide Medication by Mouth.**—Joseph H. Catton conducted examinations of the spinal fluid of persons under iodide medication to determine the presence of organic or inorganic compounds. of iodine. Study 1 included observations on five patients on routine iodide medication, and Study 2 observations on one person to whom very large doses of iodides were given. Two tappings were made, and at the first one as much fluid as possible was withdrawn; the second tapping being made some time later to ascertain whether or not the newly secreted fluid contained a greater amount of iodine, if any. As a result of the observations made Catton draws the following conclusions: 1. In the series of cases examined, regardless of the amount of iodine administered by mouth, no iodine or compounds of iodine were found in the spinal fluid. 2. Either iodine compounds do not pass the ependymal cells of the choroid plexus in any measurable quantity, or such iodine as does reach the spinal fluid is very rapidly fixed in the tissues.

2. **Trench Fever.**—Arthur F. Hurst gives a report of "Trench Fever" as he found it while working among the British troops in France and Salonica. In France the disease was only observed among officers and men living near the trenches and in the personnel of hospitals in which there were patients suffering from the disease. No cases occurred among ammunition columns, ordnance and headquarters' troops. For this reason the condition received its name, though actual residence in the trenches was not an essential factor. The writer's attention was first drawn to the disease in Salonica, where it became extremely common. It was found that trench fever could be transmitted to healthy soldiers by the intramuscular or intravenous injection of the blood of men suffering from the disease. Injection of the washed red corpuscles had the same effect, but the plasma and serum were not infective. One attack does not seem to protect against reinfection. As yet no infective organisms have been found, but the evidence pointing to an intracorpuscular infection suggests a protozoal rather than a bacterial origin. Since the disease produces no nasal, pharyngeal, or bronchial catarrh, and seldom any gastro-intestinal symptoms, it is probable that it is conveyed through the intermediation of some insect, and the most common one at all seasons is the louse. Cold, wet and fatigue appear to be exciting causes in a man who has become infected. Hurst observed that the incubation period is between fifteen and twenty-five days. The symptoms resemble somewhat those of influenza, but without the nasal or bronchial catarrh. The onset is abrupt, and there is marked tenderness over the shins —one of the diagnostic features—with marked fever ranging from 102° to 104°. There are two forms of the disease, the short form, which lasts from five days to a week, and the long form, in which there is a periodic return of symptoms, and the temperature falls more gradually. In this last form the total duration of trench fever is generally between four and six weeks. Men suffering from this condition should be kept together when sleeping, but could work with other soldiers when able. The treatment is not extensive, acetylsalicylic acid being the most effective analgesic drug. The bihydrochloride of quinine given subcutaneously when the temperature rises above 99° appears to put an end to relapses in prolonged cases.

4. **The Late Sequelæ of Frambœsia.**—Philip Harper states that locomotor ataxy, general paralysis of the insane, and aneurysm, well recognized as sequelæ of syphilis, seem to have been generally overlooked as remote results of frambœsia. This disease is common among Fijians, while syphilis does not exist. We can be sure that the disease which is universal to Fijians is yaws, or frambœsia, and not syphilis, because (1) of its symptomatology and physical signs, which are different from syphilis; (2) the fact that the disease is not hereditary; (3) the therapeutic tests; and (4) that there is not a single absolutely certain case of primary syphilis in a Fijian nor of any hereditary syphilitic manifestations in Fijian infants. Harper cites a few cases of tabes and general paralysis of the insane occurring in one district medical officer's routine practice in a district of 6000 Fijians. Aneurysm is exceedingly common among these people. The cases given show in a small measure the high rate of such nervous disease among the Fijians, but since the entire Fijian population has been infected with yaws, probably the case-rate following this condition might not differ greatly from the same following syphilis.

5. **Wound of the Portal Vein.**—W. H. C. Romanis reports a case of shell wound of the abdomen, in which the fragment of shell passed through the abdomen from front to back without injuring any portion of the intestinal canal. An Australian soldier was wounded by high-explosive shell at 4 A.M. on July 5, the fragment entering just below the left costal margin, one inch to the left of the ensiform cartilage. Seen late the same evening, patient's condition was bad; vomiting, with rigid abdomen, tenderness marked over the epigastric region, pulse 120 and thready. Laparotomy performed under chloroform through the left rectus twenty-three hours after the wound, and the abdomen found to contain a large quantity of fresh blood. A track was traced to the right, through the left lobe of the liver, emerging on its under surface, through the lesser omentum and tearing a lateral hole about half an inch long in the portal vein from which blood was freely gushing. A plug was placed in the liver wound and two artery forceps were clamped on the side of the vein in a longitudinal direction, controlling the hemorrhage. The track of the missile passed on just to the outer side of the second part of the duodenum and pierced the peritoneum of the posterior abdominal wall here. The fragment was followed no farther on account of patient's condition. Stomach, small intestine and transverse colon showed no perforation. Wound was closed after mopping out blood from abdomen, with plug and forceps left *in situ* with handles emerging from upper end of the incision. Patient improved, and

plug removed on second, and forceps on third day. Improvement continued until eighth day, when patient was taking solid food. On evening of eighth day, he complained of severe hypogastric pain, vomited twice, and passed some urine containing much blood. His abdomen remained soft and mobile, but his pulse failed and he died in an hour. Postmortem showed good condition of tissues along the path already investigated, but a large retroperitoneal hemorrhage was present around the right kidney, and an ulcerated hole was found in the right renal artery on its posterior aspect, close to which lay a small jagged piece of shell-case, a little larger than a green pea. Death was apparently caused from secondary hemorrhage from the renal artery on the eighth day.

7. On the Life-History of the Meningococcus and of Other Bacteria. J. G. Adami.

2. Retraction of the Uterine Muscle Associated with Obstructed Labor.—H. T. Hicks says that his reason for again bringing this subject forward—he first referred to it in 1906—is because he knows that this condition is not often recognized and that he has altered his views in the light of further experience. The patients are all primiparæ and with some pelvic bone deformity, such as rickets, etc. The patient has come to term and labor has just begun and the fetal head is felt just above the brim. The uterine contractions continue, but there is no attempt at bearing down, and patient complains of a continuous uneasiness about the abdomen. The fetal head is still above the brim and with the examining hand the retracting ring will be found just above the head. Cæsarean section is the only safe means of delivery. Hicks makes the following conclusions: 1. Be on your guard when dealing with a short, thick-set woman with a square head and short long bones. 2. A high position of the fetal head, occurring in a primipara, should at once denote serious trouble. 3. Measure the diameters of the pelvis, but do not place too much store upon your estimate. The brim may be obliquely distorted, and this will prevent the head from entering the brim and at the same time will not show up in your calculations. 4. Cut-and-dried rules on pelvimetry are useful only in severe contractions of the pelvis. 5. Remember that to apply forceps to a fetal head which is movable and high above the brim is an obstetric operation requiring the most careful consideration, and should only be undertaken after careful examination of the condition of the uterine muscle around the neck of the fetus. If the examining hand can be passed easily beyond the shoulders of the fetus, an attempt at delivery with instruments may be made. If there is the least evidence that the uterine muscle is retracting round the neck of the fetus, Cæsarean section should at once be performed. When once the retraction ring has formed around the neck of the fetus, it will grip it firmly until the patient is almost at the point of death.

3. Breathlessness in Soldiers Suffering from Irritable Heart.—Thomas Lewis, Captain Cotton, J. Barcroft, T. R. Milroy, D. Dufton, and T. R. Parsons contribute a full report to the Medical Research Committee in which they wish to call attention to another and more subtle cause of breathlessness than the ordinary causes. The cause of breathlessness to which they refer is the absence of an adequate supply of "buffer" salts in the blood; this condition is found among patients who are diagnosed as having "irritable hearts," or "trench hearts," that is, among soldiers invalided. They have no contant physical signs, but upon moderate exertion there are excessive fatigue, faintness, giddiness, increased pulse rate, and even while at rest, high respiratory rate. Now the blood is at all times receiving and parting with acid and alkali; buffer salts, Na_2HPO_4, and NaH_2PO_4, in the presence of CO_2 produce an increase in the acid reaction of the blood, and ease the shock to the reaction of the blood by the addition of acid or alkali. These observations seem to the writers important because they demonstrate an altered state of the blood which goes far to explain the otherwise inexplicable breathlessness in certain patients who suffer from the condition described as irritable heart.

4. **The Estimation of Myocardial Efficiency.**—J. Strickland Goodall bases his conclusions on the study of 2,000 observations made on healthy and diseased hearts during the past five years. The measure of a heart's efficiency is its capacity for doing work, whether one is dealing with a healthy or diseased heart. The physiological heart of a healthy young adult responds to increased work by increased contraction—increased rate, blood pressure, and respirations. In the diseased heart in which the myocardium is at all impaired the response to work is not by increased contraction, but by dilatation, so that, although the frequency is increased (often out of all proportion to the amount of exercise taken) the blood pressure fails to rise or actually falls, according to the amount of damage present in the heart and the amount of work done. The writer tested these statements by the following methods: the simple stair test, the exerciser test, the inclined plane test, and the progressive exercise reaction. These various exercises have all been found beneficial in many cases of myocardial disease and when carried out quietly, systematically, and over sufficient length of time protects the sick heart by estimating its limitation of power to work.

6. **Epidemic Cerebrospinal Fever: The Place of the Meningococcus in Its Etiology.**—Edward C. Hort and Alfred H. Caulfeild have devoted much time to the work, and Hort has shown that the cerebrospinal fluid in acute cases of this disease in man sometimes contains a filter-passing virus which is not the meningococcus, but which is nevertheless capable of producing continued fever and death when injected into monkeys. They draw the following conclusions based on intraperitoneal and subcutaneous injection 1. The pathogenicity to monkeys of cerebrospinal fluid from acute cases of cerebrospinal fever appears to tend to vary inversely as its meningococcal content. 2. The cerebrospinal fluid in this disease sometimes contains a filter-passing agent which is not the meningococcus, but which is nevertheless capable of producing in monkeys continued fever or death. 3. This filter-passing agent appears to be a living virus capable of cultivation in the laboratory, and of passage through monkeys. 4. None of the pathogenic results here recorded can be reasonably attributed to the action of living meningococci as such, or to the direct or indirect action of a meningococcal toxin. 5. The pathogenicity of cultures of the meningococcus appears to be due to the concomitant presence of the filter-passing virus described. 6. The pathogenic effects observed in the monkeys injected, whether with cultures of meningococci, with filtered or

unfiltered cerebrospinal fluid, or with cultures of X, did not include gross pathological changes in the cerebrospinal system.

Berliner klinische Wochenschrift.

October 2, 1916.

Diabetes Innocuus.—Rosenfeld delivered a lecture on on this subject as far back as May 15, 1914, yet it has just arrived at publication. The term was originally proposed as a substitute for diabetes innocuus, the latter being too ambiguous. These cases bear a certain relationship to renal diabetes, in which condition it had been shown that the amount of sugar excreted was not beyond the capacity of normal kidneys under functional testing, as indicated especially by blood tests for sugar. In all such cases carbohydrate tolerance could be excluded as a factor. Porges showed that the diabetes of pregnancy was as a rule of renal origin. It was shown that this so-called type of innocuous diabetes might have a familial incidence. Familial diabetes (excluding the pancreatic type which may also be familial) was especially studied by Solomon, who showed that while blood analyses in these cases were chiefly negative, exceptions occurred in which the normal sugar content of the blood was increased. The balance of Rosenfeld's article is devoted to a concurrence of twelve cases of diabetes in several families, increased considerably by including relatives not actually seen in person. In the older generations diabetes was present as a spontaneous phenomenon, lasting in certain cases for decades. In certain of the descendants the glycosuria was manifested only under a diet rich in carbohydrates. The patients were often relatively young when the disease first appeared, as is often the case with malignant (pancreatic) diabetes. But while in the latter malady the patients quickly succumb, in these so-called innocuous cases they may, as already stated, live for decades, while presenting at times clinical evidences of mild diabetes (furunculosis, etc.). However, these familial cases appear to have nothing in common with the renal form, aside from the fact that both are harmless. Renal diabetes may be due to increased permeability of the kidneys, while in the familial type the converse may be true, as is the case in adrenalin glycosuria. In fact, there is much to suggest that the diabetes innocuus of the author has a suprarenal origin (such as the relatively constant value of blood sugar). In this type carbohydrate tolerance is extreme. Women in these families may be allowed to marry. But great pains must be taken to exclude cases of pancreatic diabetes.

Therapy of So-called Acetone Vomiting. — Janssen cites Hecker's opinion that acetonuria is the result of certain metabolic crises in children, in which acetone is expelled by the stomach, lungs, and kidneys. In milder cases vomiting may be absent, the patient suffering from digestive disturbances, constipation, nausea, prostration and acetonuria. The affection attacks by preference children of the well-to-do and may be familial and hereditary. The first crisis of vomiting usually comes on suddenly and without prodromes, and the child seems very ill. It continues to vomit at intervals, and the slightest morsel of food is rejected. Thirst soon appears as a result of the dehydration, and constipation is another obvious consequence. The urine and breath are loaded with acetone. The attacks last for two or three days and are followed by complete recovery. In the opinion of the author a nervous component is present. Spasmophilia often coexists. A survey of case histories shows great diversity in type, the presence of acetonuria being the most constant phenomenon. Thus a child aged four had been nourished largely on milk and butter. A crisis of vomiting attacks suddenly appeared. The treatment consisted of an enema of warm tea, to be retained. The patient slept all night, waking in good condition. There was no second crisis. A nervous breast-fed child, aged nine months, had a brief attack of acetone vomiting and was given a little soup and warm mineral water. Other cases cited included infants and children with history of overeating of fat, or presence of spasmophilia or with no evident antecedents. Nearly all showed the presence of acute pharyngitis. The author does not seek to explain this phenomenon, and does not appear to connect it with irritation by the vomitus. The ideal treatment appears to be to distend the stomach mechanically by water or tea taken *per os*, or to fill the colon by enemas of the same. This fluid perhaps causes the poisonous material to escape by the kidneys. There seems no doubt that it can cut short the crisis. The article of food best tolerated is potato soup or mashed potato. The kind of water taken is immaterial, but it must be taken hot and sweetened with saccharin. There is further a psychic factor in the successful treatment of these cases—the personality of the medical man.

Persistent Lanugo as a Sign of Constitutional Inferiority.—Paulsen states that Freund and Hegar upheld this view twenty years ago. Sellheim believed persistent lanugo an indication of future tuberculosis. The contention of Paulsen is best shown in the numerous case histories appended. The first case cited in a girl of 6½ years is one of bronchial gland tuberculosis associated with lanugo on the trunk, running from head to sacrum on either side of the spine; also over the shoulder blades and upper arms. In a similar case a girl of 13 showed also defective dentition and hyperidrosis. There were several other cases of bronchial tuberculosis. Other patients showed actual or latent pulmonary tuberculosis, the phthisical thorax, visceral tuberculosis, etc. There was as a rule a bad family history suggesting hereditary inferiority, and various somatic stigmata were present aside from those already mentioned. The presence of lanugo in unaccustomed localities was sometimes associated with scantiness of hair in normal regions. This irregularity agrees well with defective development of the teeth as pointing to an aberrant development of the ectoderm. This association was seen in but one patient of the series and recalls the "dog faced" type of hypertrichosis in which dental defects are uniformly present. Thoracic anomalies of development are common — thorax asthenicus, funnel breast, etc. Persistent lanugo also suggests a form of infantilism, and the notable lack of pigment in some of the patients points in the same direction. Such problems must be left to the future for solution.

Münchener medizinische Wochenschrift.

September 19, 1916.

Etiology of Five-Day Fever.—Werner, Benzler, and Wiese add to an earlier communication the proof that five-day fever can be transmitted from man to man, thus showing that the causative agent is present in the blood. Werner sought to infect himself with the blood of a patient injected subcutaneously. The results were negative. Next both Werner and Benzler had themselves injected by the intramuscular route, and in both men the disease developed. The incubation period was twenty and twenty-three days respectively and the disease set in with general pains and fever. The curve of the latter was characteristic. Attempts were now made to grow anaerobes from the blood. After some

negative results they succeeded, with a culture of anaerobes one month old from the blood of infected men, in causing an infection in dogs and cats which in a high degree resembled five-day fever in man. It is not claimed that anaerobic bacteria are themselves the cause of the disease but cultures of the latter contain certain peculiar granules which may be pathogenic or not, according to circumstances. The real cause of the disease is probably an ultra visible virus.

Acne Necrotica and the Use of Tobacco.—Weinbrenner saw several years ago a patient with acne necrotica on the forehead and hairy scalp who gave a history of a stomach disturbance, as a result of which he abandoned smoking for the time being. During the period of five or six weeks his skin disease which had been refractory to treatment disappeared spontaneously, but returned promptly when smoking was resumed. Since this episode he has treated seven other cases of acne necrotica in patients who were all smokers save one who chewed tobacco, and who was the most seriously afflicted. But two of the seven had stomach disorder, which, as one knows, is very apt to be present in this disease. The author has searched literature in the vain hope of finding mention of some connection between the eruption and the tobacco habit. In every one of his patients the disease healed spontaneously when tobacco was given up, although the tobacco chewer who also suffered from gastric disorder proved to be far more refractory than any of the others. Trial breakfast in this case showed no disturbance of normal acidity. Acne necrotica seldom or never occurs in women (the author has never seen a case). In case reports by others there is no allusion whatever to the use or abuse of tobacco. That the amount of tobacco used plays a very small rôle is shown by the fact that one patient smoked but two or three very small and mild cigars daily.

Treatment of Furuncles in the Troops.—Kastan states in regard to furunculosis that efforts are devoted chiefly toward local extension and recurrent attacks. A boil or carbuncle is treated as follows: the surrounding skin is carefully shaved and ordinary grey ointment thinly but evenly applied. The lesion must not be covered and at the proper time should be lanced and allowed to discharge pus. A small, moist wick drain is then inserted with a moist dressing over all. This dressing may be medicated with very dilute solution of acetate of aluminium. The most that such treatment can do is to hasten the expulsion of the core. The author has tested many local applications and combinations of the same upon the troops and has arrived at certain conclusions, thus ointments should never be removed before adding others, since it is best to continue to add new ointment above the old. The moist dressings are changed daily at first, but in order not to interfere with the ointment, the interval is soon lengthened to three or four days. In order to explain the efficacy of grey ointment the author assumes that the metallic mercury is volatilized and diffused so that it thereby becomes able to destroy the pyogenic cocci of the lesions.

Le Progrès Médical.

September 20, 1916.

Recrudescence of Malaria in Ancient Foci in France.—Etienne refers first to the reappearance of malaria in certain small foci in Flanders, and then mentions that in Paris conditions are not only favorable for such an awakening, but that cases have occurred in small areas both within and without the city. In Paris are numerous sufferers from chronic malarial infection, while a form of anopheles mosquito is quite common in the city. Already numerous reports have been received of small group infections in various localities. The author has had personal knowledge since 1915 of paludism in the Seille valley, where the disease has prevailed in the past. The *Anopheles maculipennis* is known to inhabit this locality. The author, who has known this region since 1888, has never observed an inoculated case of paludism, although some of his colleagues have made positive claims which may perhaps have referred to cases of grippe. However this may be, the author in 1915 encountered a group of six cases of undoubted malaria, in three of which the hematozoon was found in the blood. Certain prodromes of the disease suggested rheumatism. As the cases progressed diagnosis became assured, the disease developing in typical fashion. In one patient only there was a marked history of mosquito biting. To explain the group of cases it is easiest to assume that the old infection had never died out. It had persisted for decades in a larvated form, having been screened by the occurrence of other infectious diseases like influenza and rheumatism. The recrudescence of the disease must have been due to the upturning of the soil in connection with trench work. Those with latent malaria now exhibited an active type which could readily be spread by the anopheles.

The Contractures of Late, Prolonged Tetanus in Comparison with Those of Organic Disease and Hysteria.—Claude and Lhormitte refer to the very great number of contractures in wounded soldiers. One muscle or a group may be attacked. The exact relationship between injury and contracture has from the first been obscure. In some cases a reflex mechanism, in others a neuritis has been invoked, while the neurologists believe in a reflex in association with hysterical fixation. Recently it has become apparent that another type of contracture exists which has little in common with the others, although there could be an association between them. In tetanus cases contractures supervene soon after injury, and the muscles affected show a peculiar rigidity before becoming contractural. Naturally the major manifestations of tetanus are not in evidence. The fingers may be flexed to the utmost and completely immobilized to the strongest attempts at reposition. A reflex component may be demonstrated. The central nervous system appears intact. Generally speaking, the mechanical and electrical excitability is greatly increased. The facial muscles show a sort of mask-like rigidity, and the masseters and nuchal muscles appear to be in a state of tonic contracture in but few cases. No real trismus is present, although the mouth cannot be fully opened. In a similar fashion one limb or only a segment of a limb may become contractured perhaps several months after the injury. In some of these late chronic cases of tetanus the symptoms persisting longest are trismus and rigid abdominal muscles. As a rule there should be no diagnostic confusion between these cases and contractures due to organic disease of the pyramidal tracts. The authors speak as if this abortive form of tetanus is quite common, but differentiation between it and functional types is often most difficult. Its relationship to typical tetanus is not made clear, for example, in reference to previous attempts at immunization. It is extremely persistent, but has thus far, in the author's experience, been without mortality.

Resistance of Spirochetal Foci to Salvarsan.—Wechselmann and Arnheim refer to foci of spirochetes in the region of chancres clinically cured by salvarsan. This can only mean that treatment was not intensive at the outset. Whenever the Wassermann reaction has become negative, the chancre should be completely cicatrized, free from spirochetes, and non-inoculable.— *Deutsche medizinische Wochenschrift.*

Profilaxis del Tifus Exantemático. Por el Dr. D. Manuel Martin Salazar, Inspector-General de Sanidad. Madrid: Enrique Teodoro, 1916.

This pamphlet is issued by the National Department of Health, and is naturally a sound, conservative presentation of what we really know of the disease in question. The author appears to follow quite closely the teachings of Nicolle, director of the Tunis Pasteur Institute, who has had extensive experience with the disease at first hand. Of much interest is the apparently well-founded claim of Cortezo for priority in antilouse campaigns against the disease. Such a campaign was waged in Madrid in March, 1903, and was promptly reported to the International Conference for Public Health in Paris. Cortezo's measures are said to differ in no wise from those in use at present, although no mention is made of the great advance of such sanitation among the warring armies during the past two years. About 2,000 cases have been reported in Spain since 1911, with deaths amounting to 311.

Infections of the Hand. A Guide to the Surgical Treatment of Acute and Chronic Suppurative Processes in the Fingers, Hand, and Forearm. By Allen B. Kanavel, M.D., Assistant Professor of Surgery, Northwestern University Medical School; Attending Surgeon, Wesley and Cook County Hospitals, Chicago. Third edition. Thoroughly revised. Illustrated with 161 engravings. Price, $3.75. Philadelphia and New York: Lea & Febiger, 1916.

This work has passed so rapidly through two editions, that there is little more to be said in commendation of it than has been said already. The present edition has been thoroughly revised and two chapters have been added, one dealing with the "Relation of Acute Infective Processes to Industrial Pursuits," and the other with "Plastic Procedures Instituted for the Correction of Deformities." The work is valuable mainly, perhaps, on account of its practical character, and for this reason in particular, should prove of great use to the practitioner.

Clinical Disorders of the Heart Beat. A Handbook for Practitioners and Students. By Thomas Lewis, M.D., D.Sc., F.R.C.P., Assistant Physician and Lecturer in Cardiac Pathology, University College Hospital; Physician to Out-Patients, City of London Hospital for Diseases of the Chest. Third edition. Price, $2. New York: Paul H. Hoeber, 1916.

This is a thoroughly revised edition, to which, although a few additions have been made, the teachings of the earlier editions are preserved in their original form. In order to keep in touch with the most recent advances in the study of the heart beat it is almost essential to possess Lewis's Handbook for reference.

The Catarrhal and Suppurative Diseases of the Accessory Sinuses of the Nose. By Ross Hall Skillern, M.D., Professor of Laryngology, Medico-Chirurgical College; Laryngologist to the Rush Hospital; Fellow of the American Laryngological, Rhinological and Otological Society; Fellow of the New York Academy of Medicine; Member of the Society of German Laryngologists, etc., etc. 287 illustrations. Second edition, thoroughly revised. Price, $5. Philadelphia and London: J. B. Lippincott Company, 1916.

Dr. Skillern made a somewhat new departure when he wrote in English a work treating in minute detail of nasal accessory sinus diseases and their treatment. The only work in the English language in which an attempt has been made to do this is that of Logan Turner, the Edinburgh specialist, and his work is hardly adaptable as a general text book. Consequently the only available sources of information in the direction are German and French books. However, Dr. Skillern has removed the cause of reproach from English nose and throat specialists, as the work which he has produced and which has quickly run into a second edition, equals in all essential features any work of a similar nature. The present edition has been amplified, and these amplifications include the treatment of sinus disease in children; the use of the nasopharyngoscope in diagnoses of obscure conditions in the posterior ethmoid and sphenoid region. Canfield's operation on the maxillary sinus compared with the preturbinal method with instructions for and illustrations of both the immediate and ultimate effects of operation on the sinuses. The work has undergone a complete and systematic revision. A hitherto almost neglected subject, that of the after treatment of sinuses upon which an operation has been performed, is thoroughly discussed and, indeed, the whole work provides an exhaustive and analytical résumé of the matter in question. The illustrations are excellent.

Burdett's Hospitals and Charities, 1916, being the Year Book of Philanthropy and the Hospital Annual, Containing a Review of the Position and Requirements and Chapters on the Management, Revenue and Cost of the Charities, an Exhaustive Record of Hospital Work for the Year. By Sir Henry Burdett, R.C.B., K.C.U.O. Author of "Hospitals and Asylums of the World," "Hospitals and the State," "Pay Hospitals of the World," "Cottage Hospitals," etc. Editor of the *Hospital*. Twenty-seventh Year. Price, 10 shillings. London: The Scientific Press, Limited, 1916.

Burdett's is so well known that it would be superfluous to review it at length. It may be said, however, that the present issue reaches the high standard of former ones, and the result has been attained in the face of the difficulties created for the printers and editorial staff by the war. A new feature of the book is a complete list of the whole of the territorial hospitals, their exact locality, and the name of the principal nation in each case. It may be mentioned that Sir Henry Burdett initiated the work of which he has been editor since its introduction; that he is now seventy years of age, fifty of which have been spent in laboring continuously for the voluntary hospitals of Great Britain. He has raised to himself *monumentum ære perennius*. and has earned the lasting gratitude of his fellow countrymen.

Diseases of the Skin. By Richard L. Sutton, M.D., Professor of Diseases of the Skin, University of Kansas School of Medicine; Former Chairman of the Dermatological Section of the American Medical Association; Member American Dermatological Association, etc. With six hundred and ninety-three illustrations and eight colored plates. Price, $6.50. St. Louis: C. V. Mosby Company, 1916.

It requires courage, optimism, and enthusiasm to write a new book on the skin when twenty competitors, including late editions, are accessible in the English language alone. The work comprises about 900 pages and is hence a treatise. It seems in no sense a personal book and the author has derived much of his material on rare and exotic diseases from the best authorities. He has surprisingly little to say of physical measures of treatment, and is by no means up to date in this province. We do not find in his index any reference to the Kromayer lamp, to ionization, to the electrotherapy of skin diseases or to the new gasless *x*-ray tubes. There is not much over a page of text on the body louse, despite all that we have learned about the parasite during the war. The discovery that the Ducrey bacillus may act as a saprophyte in the female genitals without infecting the host is not mentioned. We see nothing of the salvarsan substitutes made necessary by the war, nor of substitutes for certain other German drugs, the price of which is now prohibitive. Any author who writes a treatise owes it to his patronage to make a final attempt to incorporate all very recent discoveries, even if he has to use foot-notes. The excellencies of the book are many, and since nearly all good text-books on dermatology have later editions, the author will have plenty of opportunity to rectify the omissions in the present work.

Roentgenographic Diagnosis of Dental Infection in Systemic Diseases. By Sinclair Tousey, A.M., M.D., Consulting Surgeon, St. Bartholomew's Clinic, New York. Price, $1.50. New York: Paul B. Hoeber, 1916.

The relative importance of dental infection will gradually be established. At present almost every disease is being laid to an alveolar abscess. The necessity of investigating the teeth and sinuses cannot be too strongly emphasized, but an alveolar abscess may exist and yet not be the cause of the disease which is being studied. Dr. Tousey himself quotes two estimates that "10 and 60 per cent. of all artificially filled roots are abscessed," as shown by *x*-ray. The *x*-ray must for some time to come be one of the later aids in most diagnoses, because of its expense. It is, however, a recognized and important adjunct. Dr. Tousey's book will be suggestive to many.

Society Reports.

FIRST DISTRICT BRANCH OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK.

Tenth Annual Meeting, Held in Poughkeepsie, October 14, 1916.

THE PRESIDENT, DR. JAMES E. SADLIER OF POUGHKEEPSIE, IN THE CHAIR.

Election of Officers.—The following officers were elected to serve for two years: *President*, Dr. Richard A. Giles of Cold Spring; *First Vice-President*, Dr. Joseph B. Hulett of Middletown; *Second Vice-president*, Dr. George A. Leitner of Piermont; *Secretary*, Dr. Charles Ellery Denison of New York City; *Treasurer*, Dr. John A. McCord of Poughkeepsie.

President's Address. — Dr. JAMES E. SADLIER of Poughkeepsie said that in view of the excellent program that had been provided he had considered it advisable to dispense with a formal address. However, there were a few matters worthy of attention. The First District Branch had been supposed to include eight counties; only seven of these had been active hitherto, owing to the fact that Putnam County had no county society. This was because of the geography of Putnam County and lack of transportation facilities making it inconvenient for physicians from the different sections of the county to find an easily accessible and central meeting place. This difficulty had not been overcome by the organization of the Dutchess and Putnam County physicians into one society; this would prove a distinct acquisition, not only to the First District Branch but to the State Society. Another point of importance which should be mentioned was that it was imperative that the county societies should be careful in the selection of their legislative committees. Legislation of significance to the medical profession would be brought up at the approaching session of the Legislature, particularly in reference to Workingmen's Compensation; it was highly important that physicians should acquaint themselves with such legislation before it came before the Legislature. The medical profession had always stood ready to do its part to further any cause for the betterment of humanity, and they should be prepared to do their part intelligently in respect to Workingmen's Compensation legislation, so that justice might be done both to the public and to the medical profession.

The Crucial Age of Man.—Dr. W. STANTON GLEASON of Newburgh presented this communication. (See page 881.)

Dr. HENRY LYLE WINTER of Cornwall related his own experience with the crucial age. He said the excellent paper which Dr. Gleason had presented opened up a wide field to their view. In a general way, it might be said that the several clinical pictures of decline of power which one saw between the ages of forty-five and fifty-five years were the result of autointoxication. He said this bearing in mind that the definition of autointoxication was a very loose one. He supposed autointoxication meant self-intoxication. There were four very distinct varieties of intoxication which were often wrongly classed together, only one of which was a true autointoxication. The other three were (1) toxemia by infection, (2) toxemia by absorption, and (3) toxemia by alimentary intoxication. The first group, which might be called autointoxication by microbes, because they are due to the toxins formed in the organism through microbes which have entered accidentally; they were not produced under the influence of a vital process. This condition was found in any of the acute fevers or chronic germ diseases. These were not forms of autointoxication, but were poisoning by specific toxins. The second group of toxemias by absorption were just as distinct. These occurred, for example, from any chronic suppurative process. Recently they had been hearing a great deal about the disorders arising from the teeth and gums. Any of these might give rise to toxic products accompanied by indols and phenols. Their absorption gave rise to more or less accentuated symptoms. The decomposition of retained urine in the bladder, for example, might give rise to symptoms of autointoxication by absorption. A third group which must be excluded from a definition of autointoxication were the alimentary intoxications. These arose from the ingestion of foods, tainted meat, fish, canned goods, etc. In this same group one must place the milk intoxications seen in infants. This group showed itself in three classical forms: First, the pseudotyphoid form, with scarlatinal or rubriform eruption; the botulic form, a true ptomaine toxemia with negligible intestinal symptoms, but with grave nervous manifestations, such as nuclear paralysis with dystrophy, strabismus, or peripheral paralysis with aphonia, etc.; and a mucodysenteric form, which was the most common form, and with which all were familiar. In the fourth group were the true intoxications. These were caused by the toxins produced under the influence of the vital processes of the organs. These were the factors that were most likely to be at work during what Dr. Gleason had aptly called the crucial age. These toxins were derived from two sources, from the disturbance of the functions of the tissues and organs of the body, or from a disturbance of the function of digestion. For practical purposes, Combe had divided the latter into two groups: (1) The dycrasic autointoxications. (2) The gastrointestinal autointoxications. The toxic substances produced by the functions of the different organs of the body were not found at their points of origin; they were either diffused through the blood or appeared only in the different secretions or excretions, and it was often difficult to trace them to their source. A certain number of these substances were not, strictly speaking, toxic. Instead of producing true qualitative changes in the blood they produced quantitative changes affecting the isotonicity, but these changes might be severe enough to even produce death. There were two varieties of these changes, a histogenic and an organopathic. The histogenic variety occurred under varying conditions. When the nucleins were destroyed and transformed into uric acid, purin bodies, xanthin, hypoxanthin, and pxalic acid, and these substances were formed in excess into the blood, one found the uric-acid diathesis. The same state of the blood might be found in leucemia from destruction of the nuclei of the leucocytes. This group was known as the nucleolytic autointoxications. Whenever the albumin was destroyed too rapidly fatty volatile acids and large quantities of ammonia were formed and acetone was also produced. This form of intoxication was the one that occurred in the condition known as acidosis, and was known as the hypotrophic autointoxication. It was essentially the condition which the writer had seen repeatedly in nervous exhaustion. The organopathic intoxications were numerous, and varied greatly. The first group dealt with the glands of external secretion. When these glands were not equal to the task imposed upon them, one had, for instance, in the case of the kidneys, uremia; when it was the liver, cholemia. The glands of internal secretion might also be responsible for autointoxication, as mylodema due to insufficiency of the thyroid, acromegaly from insufficiency of the pituitary body, etc. Then, again, there was gastrointestinal autointoxication, which must not be confounded with alimentary intoxication. There were true autointoxications caused by quantitative or qualitative alterations in a normal digestion. These were too numerous to discuss. It was obvious that the crucial age of man began at a time when, by reason of changes in his metabolic activity, his powers of resistance began to diminish and these autointoxications appeared. The practical clinical application of all this was that every man who reached the age of forty-five years should place himself under the observation of a competent physician, and should report for examination from two to four times a year. In making an examination of the urine, one should be particularly careful to look after the nitrogen output, not only the total nitrogens, but the nitrogen of urea, of ammonia, of the purin bodies, and of the extractives. These bore a reasonably fixed quantitative relation to each other in the normal individual. A disturbance of this relation meant trouble. This information would also assist them in regulating dietary errors with reasonable accuracy.

Dr. WILLIAM SEAMAN BAINBRIDGE, New York City, said if true autointoxication were limited, as had been suggested, to disturbances of the endocrine organs, and self-poisoning as the result of lack of elimination, excluding all absorption from the respiratory, the gastrointestinal, and the urinary tracts, the vital question still remained, "*What causes these disturbances?*"

Dr. GLEASON, in closing the discussion, said that in reply to Dr. Bainbridge he would say that as a general practitioner he felt that he was on the border line. He used, as far as possible, the knowledge furnished by laboratory investigators, but in their reports from the laboratory they were so enthusiastic that the labo-

ratory did not always convince the clinician; and when it came to a break, as it were, the clinician had to use his judgment. As to the production of the conditions which they were discussing, his deductions had come to about this point: The toxins came from the intestines, or from a focus of infection, and induced changes in the metabolism and in elimination. Then there were toxins about which they knew nothing. Again, they knew that some toxins came from a focus, and that often such a focus was a closed test tube. The action of such a toxin might be different in a closed focus from what it would be if exposed to the air. This fact might have its effect on a vaccine made from a culture taken from such a closed cavity. Furthermore, a vaccine must be prepared under strict antiseptic precautions. As to the toxins, there were toxins that were not known clinically that were at work, especially in gouty conditions, as it was well known that the blood was filled with uric acid in this condition. While they had gotten as far as the uric acid in the blood, there was evidently a vista lying beyond of which they knew nothing. The laboratory had thus far touched only on the outer edge.

Address by President of the Medical Society of the State of New York.—Dr. MARTIN B. TINKER of Ithaca made a brief address, in which he spoke of his visit to the various district meetings. He said that on the whole they were very interesting and a credit to the State Society. He said he would only speak informally as to the ideals and what he wished to accomplish in the State Society. In order to do this he would take as his text the Articles of the Constitution of the State Society and would preach from them. He said the first purpose of the State Society, as set forth in these articles, was "to bring into compact organization the medical profession of the State." The membership of the Society now numbered about 8,000, and there were in the State about 15,000 physicians. Allowing for those who were irregular practitioners, there were left several thousand who were not members of the State Society. This was doing about as well as the other State societies in the United States, but not as well as they would like to do. Every qualified practitioner should be made welcome in the Society and personal likes and dislikes should have no influence. The second ideal of the Society, as expressed in the Constitution, was the "extension of medical science." Undoubtedly, every doctor had cases that would be of value if he would report them to his local society. With this idea in view, and for his own advance in knowledge, he should take careful histories and keep accurate records of his cases. The third purpose of the Society was to "secure the enactment of just medical laws." There were a number of medical societies whose only purpose was the advancement of scientific knowledge, but which had no concern with medical legislation, so that it remained to the National and State Societies to secure the enactment of proper medical laws. They would have to keep an eye on the laws affecting medical practice, and they should be familiar with medical compensation laws in connection with the Workingmen's Compensation. If physicians did not protect their own interests in these matters no one else was going to do so. The physician who had among his patients the family of a member of a legislative committee could exert more influence with such a man than some official of the State Society with whom the man was not acquainted. Here was a great opportunity for the country practitioner to show what he could do, for the time to stop objectionable legislation was not after it had reached a legislative committee; such legislation should be killed, before it reached any committee, by the local medical societies. These results could not be attained without personal sacrifice, but it was the plain duty of all to take up their responsibilities in this matter and not to leave everything to their officials. The fourth purpose, as expressed in the Constitution, was to "promote friendly intercourse among physicians." There was a tendency to pettiness and jealousy in small communities; the best way out of this was for physicians to get together and all take an active interest in the local and State societies. The fifth purpose of the Society was "to guard the material interests of its members, and this was especially a question of medical defense against malpractice suits. There seemed to be a large number of unscrupulous people who thought they saw an easy way of getting money by suing the doctor, and the best assurance against this danger was to be found in membership in the Medical Society of the State of New York, whose attorney had been more successful protecting its members against malpractice suits than any other in this country. The sixth purpose of the Society was the "enlightenment of the public as to the state of medical science." The medical profession had always been a great deal in advance of actual practice in its scientific knowledge. For instance, twenty years ago physicians knew the cause of typhoid fever and how to prevent it, yet it was only five or six years ago that a city like Philadelphia could be made to see the necessity of pure water supply. The public has found considerable fault with the profession because they did not know the cause of poliomyelitis, and when any one assumed this attitude it was well to call his attention to the fact that the public did not to-day take advantage of one-half the knowledge that the medical profession had given it in regard to sanitation and preventive medicine. Individually, and as a profession, our support should be given to public health work.

Experiences in Serbia During the War.—Dr. ETHAN FLAGG BUTLER of Yonkers presented this paper, in which, in order that the factors involved in the outbreak of the epidemic of typhus might be understood, he described the nature of the country, its peoples, and the progress of the war up to that time. He said the country was essentially agricultural, and facilities for transportation were very limited, it being necessary in order to reach certain places to travel by oxcart or to walk. The climate approximated that of northern New York or New Jersey. There were few towns of appreciable size, and but one city worthy of the name—Belgrade. With the exception of Belgrade, all the towns, in their architecture and lack of sanitation, showed the Turkish influence. The people, as a whole, were ignorant, slow to learn, and wholly devoid of the least conception of hygiene or sanitation. Their sense of honor was not overkeen, but they were brave and patriotic. Every physician was a medical officer in the army or on the reserve list. However, the organization and efficiency of the medical department of their army could not be rated very high. The strong offensive launched against Serbia by the Austrians in the early part had the effect of driving a large proportion of the noncombatant population to the central and southern part of the country. Overcrowding resulted, and the increasing number of wounded made the establishment of reserve hospital points necessary here and there throughout the land, and patients were rushed to these points even before staffs had been secured to take charge of the hospitals. The American Red Cross responded to the call for doctors and nurses, and sent out three units, the second of which was in charge of the writer. When their party reached Serbia they found themselves cut off from the other units, one of which had fallen into the hands of the enemy. They were sent to a primitive little village on the Greek border to take charge of the Reserve Hospital there located. This hospital proved to be a large warehouse with great bare lofts and unpartitioned spaces, with no running water, and no provision for the disposal of sewage or waste. Bedding of all kinds was insufficient, and laundry facilities nil. There were 850 filthy patients, most of them with infected compound fractures, and within twenty-four hours 450 were added. They had come primarily to render surgical assistance, but there was greater need of sanitation. It was under such conditions as these that typhus, which was always endemic in the Balkans, broke out. The method of handling the soldiers was largely responsible for the rapid spread of the disease at this time. In January, 1915, it became apparent that a serious epidemic existed, and from that time until the middle of April, 1915, there was a very rapid increase in the number of cases and the virulence of the disease. After that it gradually declined. While their party was in no position to investigate scientifically the etiology of the disease, there was nothing in their experience that would tend to contradict the theory that it was louse borne, and only louse borne, and particularly borne by the body or clothing louse. Lice were everywhere, and no one escaped them, but those having found few lice seemed to have been the ones to escape the disease. There was no evidence to show that infection occurred through handling the skin lesions, by dust, droplet, or from excreta. In support of the louse theory it might be stated that delousing of the patients prevented the spread of the disease, no case occurring in louse-free wards, unless they were being incubated at the time of admission. One small pavilion was kept entirely free from typhus for two months while the epidemic

was at its height solely by insisting that no patient should be admitted unless he were thoroughly deloused to the satisfaction of the authorities in charge of the hospital. At Belgrade the same thing was demonstrated. Constant vigilance was assential at all times, and none but Americans could be trusted with the important features of this work. They had had the opportunity of observing a large number of cases of typhus fever, there being 922 cases within the military hospital at Belgrade, whither they were sent after completing their service on the Greek frontier. That was the high figure for one day. The total number of cases seen was well into the thousands. There was also a series of cases occurring among Americans, Serbs, British, Italians, and other nationalities, which came under their care. A small group of patients, comprising their own staff invalids and persons of authority brought to them that they might secure the advantages of their nursing staff, afforded an opportunity to keep records and to follow the course of the disease minutely. The incubation period was from seven to fourteen days. In the majority of cases the onset was sudden, characterized by high fever and headache. The temperature remained high and the pulse rapid throughout the acute course. On the fourth or fifth day the typical skin rash appeared, petechiae, 2 mm. in diameter, increasing in number from day to day, and not fading on pressure. Throughout the course of the disease there was much headache, and pain in the extremities. A profound toxemia occurred, affecting the central nervous system, heart, and blood vessels. During the acute course there was tremor, incoordination, involuntary passages of urine and feces, and delirium. The pulse became irregular in rate and force, and diminished in volume. The acute cases lasted from three to seventeen days, and were terminated by lysis. As the epidemic progressed the cases became more virulent and the mortality increased. Convalescence was slow, and complicated by peripheral neuritis, psychoses, gangrene of the extremities, and abscesses in most any part of the body. The true mortality would never be known. The primary rate approximated 50 per cent. and with the secondary rate, from complications and sequelae, brought the total mortality to about 65 per cent. With good nursing and special care the mortality of the cases received into the series receiving special care was 10.7 per cent. Preventive measures consisted in the thorough delousing of all patients within the hospital and prior to admission. Where there were no lice there could be no typhus. The acute cases were treated much the same as typhoid fever was treated in this country, the bulk of reliance being placed on good nursing, keeping the patient quiet and free from worry. A fairly liberal soft diet was allowed, and fluids were forced upon the patient. Toward the end of the second week, when the heart muscle began to weaken, various preparations of digitalis were used, most frequently digalen, hypodermically. In closing, Dr. Butler spoke of the lessons of the war, and commented more particularly on medical preparedness, stating that preparedness meant not only the accumulation of arms and munitions, but chiefly in the thorough training of the maximum number of able-bodied males in the military duties that they were logically qualified to perform in times of war. This applied with peculiar force to the doctors. From personal experience at home and abroad it was evident that it was no more feasible to take doctors from civil life and place them on active duty as medical officers of the army than it was to recruit a regiment and then send it, without further training, to the front. It rested with each member of the medical profession to decide how far he was willing to devote himself to his country and to secure the necessary training for a medical officer's duties.

Experiments in the Use of Moving Pictures in Teaching the Technique of Surgery.—Dr. JOHN A. WYETH of New York presented this communication. He said that in the teaching of clinical surgery some general idea of the technic might be obtained by observation from points more or less removed in the amphitheatre, the practical knowledge which was absolutely essential could only be acquired by immediate personal contact with the operator. With the advent of motion picture photography they began and were still carrying on experiments in order to satisfy themselves of the value of this means of demonstrating operative technic to their classes. Operations on the cadaver and on the living subject had proved fairly satisfactory, and they inclined strongly to the opinion that with improved apparatus and wider experience on their part and on the part of the mechanician, still better results might be obtained. A gratifying feature of this work was that it was possible to send these films to medical societies all over the country, thus enabling many practitioners who could not find time to visit central clinics to profit by these demonstrations. Dr. Wyeth gave an exhibition of these pictures, showing a bloodless amputation at the hip joint, a ligation of the external carotid, operation for an inguinal hernia, and his method of injecting boiling water in exophthalmic goitre. In describing the ligation of the external carotid, Dr. Wyeth said that until 1878 this procedure was forbidden by the textbooks on the ground that the external carotid was an exception to the general rule in that it did not give off its branches in a regular manner. He felt convinced that this statement was not true and in order to prove his contention made 121 dissections and careful measurements which demonstrated that the external carotid was no exception to the laws of development. In 1878 he read a paper before the American Medical Association in Buffalo setting forth these facts and describing his method of ligating the external carotid. This procedure bore his name for a time, but the fact that he had originated it seemed to have been forgotten.

Early Diagnosis of Cancer.—Dr. PARKER SYMS of New York made this presentation, giving a lantern slide demonstration of the microscopical changes that had been observed in the precancerous stage and the early stages of cancer. He confined himself to facts concerning cancer as distinctive from epitheliomata. He emphasized the fact that cancer in its early stage was a purely local disease. The first change which manifested itself microscopically was in the nuclei of the cells; these became hyperchromatic. The next step was a slight fibrosis; then an increasing fibrosis, plugging of the acini, and infiltration and cell proliferation. Dr. Park spoke somewhat at length of the difficulties surrounding the early diagnosis of cancer and emphasized the fact that it was only the early recognition of the condition and early operation that offered any hope for the cancer patient. He reviewed the symptoms of cancer of the breast, laying stress on the fact that pain was not a prominent symptom, but the "non-restful" breast was likely to be an indication of the precancerous stage. Dr. Syms also spoke somewhat at length of the significance of gastric ulcer as a precursor of cancer.

Dr. S. W. S. TOMS of Nyack said he felt that Dr. Syms had covered the subject very thoroughly so he would only emphasize a few points. The first of these was that we should not look for physical signs of cancer as much as we did for a disturbance of function. A disturbance of function that did not clear up in a reasonable time should be regarded with suspicion. A cancer had practically the same relation to the body of the individual as a case of contagious disease had to the community. In order to protect the community the case of contagious disease must be isolated; in order to protect the individual the cancer must be extirpated in its early stage. The fact that cancer occurred in both husband and wife in a number of instances might only be a coincidence; however, it was a rather striking fact that merited consideration. Statistics seemed to reveal the rather disquieting fact that cancer was on the increase in all parts of the civilized world; the census of 1900 showed an incidence of 63 deaths from cancer per 1000 population while that of 1913 gave 75 per 1000 population. The records of Bloodgood showed that 60 per cent. of the cases could be saved by early operation. An important point which we should recognize and which we should do our part to correct was that among the laiety there was a misconception in regard to the early signs of cancer. They looked for pain, and did not recognize the fact that pain was practically a symptom of the last stages of cancer. The correction of this misconception was a missionary work which should be undertaken by the physician. Our patient should be taught that every lump was suspicious and that irritation and misplaced organs provided a basis for cancer. They had no specific rules for the early diagnosis of cancer.

Dr. WILLIAM SEAMAN BAINBRIDGE said he wished to take exception to the last statement. They had one cardinal rule and that was that they should never manipulate a tumor. He cited authoritative evidence showing that the handling of a tumor reduced the patient's chances of life 40 per cent. Many a patient who had a good chance for life lost it either before or at the time of operation through disregard of this cardinal principle.

Dr. Edward C. Thompson of Newburgh called attention to the fact that the Mayos had followed up a large series of cases in which the pathological findings had been negative and cancer developed later.

Dr. Eliza M. Mosher of Brooklyn said she wanted to make a plea for the women themselves. When a woman came to a doctor thinking she had a condition that was perhaps suspicious of cancer, she was frequently dismissed with the statement that she was only nervous and there was nothing wrong with her. This made her feel foolish, and she would decide never to consult a doctor again unless she was absolutely certain there was something wrong. When a woman came to consult a physician because her fears have been aroused that she might have a malignant condition she should be made to feel that she had done the right thing and that it was much wiser than to have neglected a suspicious condition.

Chronic Intestinal Stasis. — Dr. William Seaman Bainbridge of New York City presented this communication, which was liberally illustrated by lantern-slide pictures showing different types of stasis and methods of treatment. In a preliminary historical sketch of man's efforts to find the causes and the cure of disease, Dr. Bainbridge recalled some of the theories which, from time to time, had held sway. Among the present-day theories might be mentioned, along with the germ theory, the view that disturbances of the internal secretions bore a causal relation to disease; also that disease was dependent upon the nutrition of the tissues and the tissue-cells. The treatment of disease, therefore, was not only a question of the elimination of the toxic products of bacterial activity, but of the toxins elaborated by the tissues themselves. This had been abundantly proved by Carrel's experiments with the maintenance of life, *in vitro*, of tissue removed from the body of which it had formed a part. Failure to remove the toxins which resulted from cellular activity, invariably resulted in the death of the tissue. It was evident, then, that the faulty elimination of the products of physiological activity was a fundamental factor in the production of disease. Just what part the internal secretions played in this connection had not as yet been definitely determined, but the importance of the gastrointestinal tract in the general maintenance of proper elimination and the preservation of health, was a matter of common knowledge. The question of the prevention of disease was largely a matter of body-plumbing, which might involve any part of the human house. Dr. Bainbridge here briefly described the chief types of defective body-plumbing which lead to the condition now generally known as chronic intestinal stasis. This condition was a persistent retention or retardation of the contents in some part of the gastrointestinal canal, at certain points of predilection, where kinks or angulations of the canal resulted from undue pull or constriction by bands of adhesion or resistance. The fixation of any point in the length of the tube, with a dropping of the tube on either side of this fixed point, produced a kink or an angulation, and this, in turn, interfered with the onflow of the contents of the canal. This stasis of effete material was followed by absorption, autointoxication, and a long chain of symptoms varying in degree with the degree of interference with drainage. The toxic symptoms were thus secondary to the mechanical changes. Chronic intestinal stasis was to be differentiated from chronic constipation, which was confined to the lower bowel. Either constipation or diarrhea might accompany stasis. Cases of stasis were classified, according to the degree of stasis and the severity of the symptoms, into: (1) Beginning cases, in which a definite condition of stasis might be prevented by proper dietary and hygienic conditions; (2) mild cases, in which, in addition to the preventive measures, it might be necessary to resort to moderate surgical interventions, such as the cutting of bands, replacing hollow organs, changing angles, and otherwise restoring normal relations; (3) advanced cases, in which radical surgical measures were demanded, such as ileo-colostomy (short-circuiting), or ileocolostomy with colectomy. After surgical treatment, by conservative or radical measures, the cases were then replaced in the first group, and were to be kept under the surveillance of the family physician or gastroenterologist, for the purpose of continuing, as long as necessary, the prophylactic measures employed in the beginning cases. If this post-operative treatment were neglected, recurrence of the severer condition would be imminent. Dr. Bainbridge emphasized the fact that the first and second groups were by far the larger, and that the radical measures employed in the third group should be resorted to only when absolutely obligatory, and after the simpler measures had been ineffectually utilized, or had been ruled out by careful examination by the various diagnostic measures now available.

Dr. Eliza M. Mosher of Brooklyn said that there were many of these cases that should not reach the surgeon, and it behooved medical men to ask themselves what they were going to do about these patients. The first thing to do was to make a correct diagnosis. They could not hope to gain the dexterity and acute sense of touch that Dr. Bainbridge and Dr. Lane had attained, that was beyond the average man, but they could be a little more careful in their observations. When a patient came into the office with bad posture, stooping shoulders, narrow chest, and the symptoms that went with enteroptosis, he should be able to recognize the fundamental cause of that patient's ill health. A great deal could be learned in these cases by the use of the stethoscope, applying it successively over the different parts of the stomach and abdomen. The patients which Dr. Bainbridge had designated as belonging to the first group could be cured or greatly improved by proper treatment. In addition to the regulation of the dietetic and hygienic habits of these patients a properly fitting abdominal belt would do much toward the restoration of the viscera to their normal position. Dr. Mosher showed the belt which she had devised and which she had employed in some 324 cases during the past few years. The belt was so constructed that it held up the recti muscles, and if these were held up the side muscles would stay in their proper position. Yawning and deep breathing were to be recommended, as they restored the viscera to their normal positions. During a yawn the abdominal muscles were flattened and drawn up, and throwing back the head raised the diaphragm and restored the viscera to a more normal position. Dr. Mosher cited an instance in which a subsequent operation showed a most remarkable development of the abdominal muscles which had been secured by these exercises, and in closing emphasized the fact that many physicians were culpable of allowing enteroptosis to pass unrecognized and not properly treated.

Dr. Edward C. Thompson of Newburgh said what they had just listened to was valuable not only in that it pointed the surgeon to big endeavor, but because of the fact that it pointed the general practitioner to the need of more careful diagnosis. It brought out the idea that the ability to make a careful diagnosis was of as much or more importance than the mechanics of surgery. The ideas which Lane had brought out really meant fewer operations, fewer sewings up of kidneys, fewer appendectomies, and fewer major operations, and it was to be hoped that when the surgeon did operate he would have the intelligence to lift up the ileum.

Dr. James E. Sadlier of Poughkeepsie said he expressed his appreciation of what Dr. Bainbridge and Sir Arbuthnot Lane had done for the profession in bringing out the importance of the condition which they had designated colonic stasis. He also accentuated the importance of post-operative care. Proper post-operative care was a most important factor; many of these cases returned to a sedentary life, and unless their diet and hygiene was properly regulated they could not be put back into the well class.

Diagnosis and Treatment of Acute Infections of the Nasal Accessory Sinuses.—Dr. Milton A. McQuade of Poughkeepsie read this paper. He said he had chosen this subject because these infections in the great majority of cases followed influenza and acute coryza, or occurred as a complication or sequela of some infectious disease, and it was the family physician whose advice and treatment were sought. He outlined the anatomical and physiological points which helped to an understanding of the process of acute infection, calling special attention to the fact that the nasal accessory sinuses were rudimentary in childhood and not fully developed until the age of fifteen to eighteen years. This accounted for the fact that there was little sinus involvement in the acute coryzas and infectious fevers of early years. Lindenthal had shown that the influenza bacillus was the most common cause of acute sinus involvement. Diphtheria and croupous pneumonia were frequently complicated by acute sinusitis due to direct invasion. The other infectious fevers might be an etiological factor from lowered vitality. Dental caries was responsible for about 20 per cent. of antrum suppuration. Tuberculosis, syphilis, malignancy, and osteomyelitis were infrequent causative factors. The primary infec-

tive organism might disappear, allowing the germ of secondary infection to continue the disease; these were most frequently members of the streptococcic and staphylococcic groups. The symptoms of infection of the nasal accessory sinuses were fever and circulatory disturbance, usually facial congestion, occluded nares, nasal discharge, general irritability, depression, restless sleep, and often visual disturbances. Headache was nearly always present, but very variable as to location, duration, and intensity. As a rule there was more or less neuralgic pain in and about the affected cavity; referred pain might occur along the branches of the trigeminus. Yankhauer had noted that if steam inhalations relieved the headache, one could believe the cause to be in the nasal chambers or sinuses. Tenderness under the floor of the frontal sinus, directly above the inner canthus was pathognomonic of inflammation of this sinus. Antral tenderness was occasionally present but was variable. Purulent secretion from the nasal chambers to be pathognomonic of sinus disease must constantly reappear in the vicinity of the sinus opening. Cacosmia, or an offensive odor in the nose, was most pathognomonic of sinus disease. Transillumination as an aid to diagnosis was of comparative value only, due to irregularities in the thickness of the bony walls and septa, and the difference in the size of sinuses. The *x*-ray was also of little value in the early stage of the inflammation, but later it might enable one to determine the condition of the sinus and its size and position in case operative interference became necessary. Suction was occasionally of value in purulent cases. In the antrum, puncture and washing was the surest way to demonstrate secretion. When the maxillary antrum was involved pain was usually referred over the orbit and around the upper teeth and jaw. There was a feeling of distention and pressure, which might not necessarily be due to pent-up secretion but might be due to swelling of the mucosa. The anterior antrum wall might be sensitive to pressure. Transillumination might show a darkened area as compared with the opposite side. This might be confirmed by *x*-ray, by suction, and by washing. In involvement of the frontal sinus there was referred pain along the supra- and infra-orbital branches of the fifth cranial nerve and pain referred directly to the sinus dull, expanding, and throbbing rather than neuralgic. The morning exacerbation was common and often precipitated by some slight exertion, such as stooping, coughing, etc. Ethmoid involvement occurred to a greater or lesser degree with every acute coryza. The symptoms were those of a severe cold in the head, with neuralgic outshoot to the deeper structures of the eye, resulting in ocular symptoms. The diagnosis of acute spenoidal involvement was seldom made on account of the difficulty attending the examination. Here the headache was often localized in the parietal or temporal regions, radiating to one or both ears. There was a feeling as though the eustacian tubes were closed. Ocular symptoms were more marked and there was more fever and general prostration than in ethmoid involvement alone. The complications that might occur were better understood by keeping in mind the anatomy of the parts and their close interrelation. One could then understand why one might expect to find among the complication such conditions as inflammation of the retina and optic nerve, muscular esthenopia and loss of accommodation, the various forms of meningitis, and thrombosis of the venous sinuses. In the treatment of nasal accessory sinus conditions the patient should be put to bed, given a purge, mustard foot baths, and Dover's powder. Local depletion should be effected by cocaine or adrenalin only if necessary, as frequently they were inefficient and had a tendency to aggravate the symptoms. Hot alcoholic drinks should be avoided. Ice bags over the forehead and eyes were indicated if the headache was severe. After purgation had been established, aromatic spirits of ammonia should be administered, half a drachm every hour for eight to ten hours. A formula which had been used with satisfaction for years consisted of sodium salicylate and quinine, each two grains, and Dover's powder, one grain, giving a capsule every two hours. About 95 per cent. of acute inflammations would respond favorably to this treatment. In acute fulminating forms of sinus involvement operative measures might be necessary to provide drainage.

Some Clinical Experiences in Heart Disease.—Dr. J. H. M. A. VON TILING of Poughkeepsie reviewed some personal experiences with patients suffering from heart disease and allied affections and presented deductions from these. He said they should not forget that the heart was not simply a mechanism which acted according to certain definite inflexible rules, but was a very delicately adjusted living organism with great individual differences in different people. It seemed absolutely wrong to approach a patient with any preconceived fixed idea as to how high the blood pressure should be, what his heart sounds should be, etc. There was no such thing as an absolutely normal blood pressure, nor an absolute normal heart. The all-important question rather was whether that heart was able to fulfill its function satisfactorily—could the circulation be properly maintained? This question obviously resolved itself into the question, "Was the reserve force of the heart muscle intact, or was it failing?" They must realize that it was in the last instance not a defective valve nor a contracted artery which caused the failure to maintain an efficient circulation but the heart muscle which was unable to overcome the obstacles, and they must judge the strength of the heart muscle and its ability to promptly and sufficiently answer to all reasonable demands if they wished to come to a clear understanding of their patients. In that respect it did not help merely to find that the patient had a certain kind of heart murmur or a certain pulse rate while he was at rest, but it was more important to know if the patient was becoming breathless after slight exertion and it was also very important to learn how often the heart acted when called upon to perform different kinds of extra work, such as at the time of extra-physical exertion, at the time of pregnancy and parturition, during times of sickness, or times of mental strain, worry, or sorrow. The proper adjustment of heart valves and the whole mechanism of the arteries and veins made it easier for the heart muscle to maintain the circulation, and, if anything went wrong with this adjustment, the heart muscle was called upon to do more work; as long as the reserve force of the heart muscle was intact it could perform this extra work. A heart with damaged valves meant that the heart muscle had to do more work than if the valves were perfect; such a heart muscle would fail easier than if the valves were intact; but that same fact was true in different people with healthy hearts. The heart of a man weighing 300 pounds had always more work to do than the heart of a man who weighed only 150 pounds, and it seemed wrong to subject a patient to treatment, or to consider him as ineligible for life insurance just because he had a heart murmur, as long as the reserve force of his heart muscle was sufficient for ordinary circumstances. The first symptoms of a gradually beginning failure of the heart muscle were not definite dilatation of the heart, enlarged liver, ascites, or general edema; if they waited for these symptoms before beginning treatment they would not do justice to their patients. The first symptoms were rather often quite insignificant and they were almost always subjective and with no physical signs. There might be palpitation, breathlessness, distress, feeling of weakness, etc. Therefore, it seemed of the utmost importance to take painstaking histories of these patients; a good history was often of more importance and value than the physical examination to determine the condition of the heart muscle. He believed that even the electrocardiograph was of less value than an exact history with proper valuation of the subjective symptoms. Besides, he did not believe a general practitioner would ever carry an electrocardiograph in his pocket—certainly not in their lifetime. It was often very difficult to place the proper valuation on the subjective symptoms complained of by the patient. Many patients would become quite angry and perhaps leave you if you wanted straight answers to the questions; for instance, if you did not allow them to state that they had a pain in the heart, or in the kidneys, when they did not know where their heart or kidneys were, and when the pain was simply somewhere in the left side or somewhere in the back—or if you did not let the patient get by with the statement that he was unable to walk because he was paralyzed, without making him state definitely if it was merely a weakness of the muscles or stiffness of the joints, or pain, or breathlessness, or dizziness, etc., which prevented him from walking. Very often they would find that the patient had forgotten, or did not notice, that the first slight symptoms of the failing heart until his attention was drawn to it; for instance, he might not have noticed that his heart beat much faster when he walked up a slight hill, or that he had to open his mouth to get sufficient air as soon as he walked a little faster than usual, yet those slight symptoms were of great importance and

the earlier the weakened heart could be placed under a proper régime the more chance for a cure. The heart might be only secondarily affected and the case for the apparent heart symptoms might be somewhere else or, on the other hand, one might get complaints attributed by the patient to other organs which really were caused by a deficient circulation in those organs for which again the heart muscle was responsible. One of the first subjective signs of a failing heart that many patients complained of was a general feeling of weakness or exhaustion; but this was by means always of cardiac origin; it was often of a vasomotor origin. The extreme of this same condition might be fainting spells, which meant, of course, a temporary failure of the heart to sustain a sufficient circulation in the brain, but they should not forget that some fainting spells might be of purely mental origin. Mental exertion certainly had an influence on the heart, and it was true that the weakened heart could cause mental and general nervous symptoms before there was any physical evidence of organic heart lesion. It would be of extreme value if they had a definite method of measuring the reserve force and getting a definite idea of the functional capacity of the heart muscle. Unfortunately they had no absolute standard for this reserve force of the heart muscle. Each person had his own personal standard and test for the functional capacity of his heart. The object of all treatment was to prevent the exhaustion of the reserve force and to restore the more or less exhausted reserve force of the heart muscle. Rest, of course, was of the utmost importance in those cases in which the heart muscle had been weakened by overwork, but one should not forget that rest for these patients meant mental rest as well as physical rest. It was well known that many poisons would cause degeneraive changes in the heart muscle.

Dr. S. NEUHOF of New York said that aside from Dr. von Tiling's remarks regarding the assumed value of laxatives in reducing cardiac dilatations, he agreed in the main with the many excellent points that he has made. He has, for example, emphasized the great importance of careful history taking, an almost lost art. He has correctly stated that cardiac murmurs did not necessarily spell heart disease. He has quite properly remarked that most cases of so-called weak hearts were due not to organic disease but to vasomotor instability. Though it was quite true, as Dr. von Tiling stated, that an electrocardiographic apparatus could not be "carried around in one's pocket," he possibly had forgotten that the lessons to be learned from it should be carried around in one's mind and thus if not otherwise available it was of use at the bedside. By just this process of translating instrumental into clinical knowledge they have learned to readily recognize such arrythmias as auricular fibrillation and extrasystoles at the bedside. Speaking broadly, in decompensated cardiovascular cases in whom the factor of infection was either quiescent or non-existent, he attempted for therapeutic and prognostic purposes, to group the patients as follows: (1) Mitral lesions with rhythmic heart. These patients improved only slowly or sometimes not at all upon digitalis. Rest with them was an extremely important factor. (2) Mitral lesions with auricular fibrillation. Unless decompensation was extreme or long continued, these patients improved very rapidly under digitalis. The irregular cardiac activity was quickly controlled. The digitalis acted here apparently by blocking many of the discordant auricular impulses passing through the conduction system. (3) Aortic lesions with slight or moderate ventricular hypertrophy. These cases usually reacted well to rest. Digitalis was not of much value. The bromides were occasionally followed by good results. (4) Aortic lesions with extreme ventricular hypertrophy. These patients did not react well to digitalis possibly because there was not sufficient healthy cardiac muscle upon which the medication might act. Even if auricular fibrillation were present, digitalis medication was not apt to be followed by beneficial results. (5) Cardiosclerosis with decompensation. By the term cardiosclerosis, the speaker said he meant a pathological condition in which there was a varying mixture of aortic, coronary, valvular, and myocardial disease. Those with cardiac failure and with edema, with or without hypertension, were apt to react well to the Karrel diet, and digitalis and theobromine sodium salicylate on alternate days. He had modified the Karrel 1,000 c c. milk day by giving only 500 c.c. of water, tea or coffee on the theobromine days with excellent results, especially upon the diuresis and the disappearance of dropsical effusions. In cardiosclerosis, hypertension, and uremia, without myocardial insufficiency, the symptoms were mainly uremic. The therapy lay chiefly in the administration of alkaloids and the giving of purely carbohydrate diet or one low in protein and rich in carbohydrates.

Report of a Possibly Milk-Borne Epidemic of Infantile Paralysis.—Dr. JOHN C. DINGMAN of Spring Valley presented this report in which he related the circumstances in connection with a series of cases of poliomyelitis that directed attention to a small milk dairy as the source of infection. On July 23 Dr. Dingman said he had been called to attend sick children in three different and widely separated summer boarding houses. In one, called the Levine House, he found four children ill with what had been diagnosed and treated by another physician as malarial fever. They all became ill on July 20 and 22 and all presented the same clinical picture, namely, fever, vomiting, obstinate constipation, and a drowsy, soporous mental condition. Two of these cases went on to frank paralysis of the lower extremities, while the other two recovered without showing muscular weakness or paralysis. These four children had all used raw milk from a dairyman, whom he would refer to as X. Three other children in the same house who used milk from another source all remained well. The diagnosis of poliomyelitis in these children was verified by Dr. Le Grand Kerr of Brooklyn. In another boarding house called "Locust Court" was a 3½-year-old girl suffering with a similar illness, although more severe. She developed paralysis of the muscles of deglutition and speech with a slight affection of the muscles on one side of the face. She also showed meningeal symptoms. The diagnosis in this instance was confirmed by Dr. Koplik of New York. The rest of the children in this boarding house, four or five in number, escaped. Upon learning that this child also had used milk from dairyman X, Dr. Dingman said he became suspicious and on July 27 visited the premises of this man. Only two cows were kept in a very filthy barn which had never been inspected by the health authorities and the proprietor had no permit to sell milk. The house occupied by a tenant was very dirty, unscreened, and swarming with flies. All sanitary arrangements were primitive and unclean. A four-year-old boy had been ill five days and showed a beginning paralysis of the right leg. By patient questioning of the tenants it was discovered that a four-year-old son of the Russian landlord had been acutely ill with fever and vomiting on July 4, and had been in bed and unable to walk for some time. The parents had not called a doctor and the child was up and about. This boy on inspection was found to walk with some difficulty and to drag one foot. On the same day, July 23, on which the writer was called to the Levine house, he had been called to another boarding house, High View House. Here he saw a four-year-old boy who had become ill the day before with fever and vomiting. This case ran a moderate course with only slight paralysis of the right leg. The diagnosis of poliomyelitis was confirmed at the Willard Parker Hospital. This boy also had been using X's milk. There were no other cases at High View House and had been none all season and this house had its own dairy. In addition to the houses already mentioned three others were supplied by this same dairy. In one of these there were no children and the milk was not used raw. In a second house there were two families who had used X's milk but boiled it before giving it to the children. In the third house there were three children who had used this milk but the parents were emphatic in the statement that the milk had been boiled before being given to the children. The eight cases here described were the only cases which developed in or about Spring Valley up to this time and for some time afterward. The few scattering cases which did occur later in the summer apparently had no connection with this group of cases. In order to determine whether these children, all of whom came from Brooklyn, might have received the infection before coming to Spring Valley, the writer reviewed the cases more thoroughly and stated that they had been followed up at their homes in Brooklyn, and so far as a thorough investigation showed that they had not been exposed to the disease before coming to Spring Valley. Three of these children began using the milk on July 10 and in ten or twelve days showed the first symptoms of the disease. It was clear that all the children coming down with the disease were

using the milk from July 6 to 16, at the time that the Russian boy, the son of the dairyman, was in bed with the disease. Under the conditions of gross filth existing on the premises of the dairyman it seemed reasonable to believe that one or more messes of milk had become contaminated by the discharges or vomitus of the Russian boy, who became ill on July 4. The infective material was probably conveyed by flies, which had access to the sick boy and to the milk, and thus the disease was carried to the other seven cases. Strong corroborative evidence of this might be found in the following facts: (1) All of the cases had their onset either on July 20 or 22. (2) They all used the raw milk, while the families that used the same milk during the same period boiled it. (3) The milk was not chilled but delivered warm, which made it an excellent culture medium for the virus. (4) At that time all the cases of this disease reported within four or five miles of Spring Valley were among the customers of this dairyman.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

KENTUCKY STATE MEDICAL BOARD.

June 13, 14, *and* 15, 1916.

(*Concluded from page* 838.)

ETIOLOGY AND PHYSICAL DIAGNOSIS.

1. Give the etiology of vertigo.
2. What are most common causes of varicose ulcers of the leg?
3. Give the etiology of rachitis.
4. Give the etiology of lung abscess.
5. Give the most probable etiological factors in the causation of cholelithiasis.
6. Give the diagnosis of Grave's disease.
7. Give the diagnosis of psoriasis.
8. Give the diagnosis of spontaneous intracerebral hemorrhage (apoplexy).
9. Describe the various kinds of pulmonary rales and give the significance of each.
10. Give diagnosis of aortic regurgitation.

PRACTICE AND MATERIA MEDICA.

1. (*a*) Give etiology of acute lobar pneumonia in the adult, with physical signs of the different stages. (*b*) How many stages of the disease, in order of occurrence? (*c*) Give treatment for all. (*d*) What remedy is considered a specific by some authors?
2. (*a*) Name different kinds of pneumonia in children. (*b*) Give diagnosis and treatment of each kind.
3. (*a*) Define hookworm disease. (*b*) Give causation. (*c*) Mode of infection. (*d*) Treatment. (*e*) What new remedy have we, and how is it used? (*f*) Does hookworm ever simulate other diseases, and of so, what?
4. (*a*) Diagnose and treat acute indigestion. (*b*) If at all, when would you administer opiates? (*c*) By what method would you use them?
5. (*a*) Differentiate between acute and chronic nephritis. (*b*) Differentiate between chronic interstitial and parenchymatous nephritis. (*c*) Give treatment for acute and chronic nephritis, both medical and dietetic.
6. (*a*) Discuss the use of radium as a therapeutic agent. (*b*) In what diseases would you prescribe digitalis, and what precautions, if any, would you take in its use?
7. (*a*) Do you know of any specifics in medicine? (*b*) If any, name three of them, giving dose and indications for their use.
8. (*a*) How would you avoid salivation after giving calomel? (*b*) What is the usual dose of calomel? (*c*) Would you give the entire dose at once or divide it?
9. (*a*) How would you prepare a tasteless dose of castor oil? (*b*) How best give turpentine in typhoid fever, if used for some time?
10. Would you recommend any drug or drugs to differentiate between typhoid and malarial fever? If so, name them, and how would you use them?

OBSTETRICS AND GENECOLOGY.

1. Name (*a*) the female internal organs of generation, (*b*) giving function of each.
2. (*a*) What is podalic version? (*b*) Cephalic version?
3. (*a*) Give etiology of adherent placenta. (*b*) What precautions would you use in delivering one?
4. Give symptoms of pregnancy at fifth month.
5. What changes take place in the female economy at puberty?
6. How would you manage a case of antepartum hemorrhage?
7. (*a*) Give symptoms of ovarian cyst. (*b*) What treatment would you advise and (*c*) why?
8. (*a*) What is the most frequent cause of cervical ulceration? (*b*) What are the symptoms?
9. Define (*a*) menopause, (*b*) metritis, (*c*) salpingitis, (*d*) mastitis and (*e*) menstrual cycle.
10. (*a*) What antiseptic precaution would you use in the eyes of the new born, and (*b*) why?

ANSWERS.

ETIOLOGY AND PHYSICAL DIAGNOSIS.

1. *Etiology of vertigo.*—Eyestrain or paresis of one or more of the muscles of the eye, disease of the semicircular canals, dyspepsia, constipation, disordered hepatic function, migraine, excesses (in the way of exercise, alcohol, tobacco, tea, coffee), organic diseases of the brain and disturbances of the cerebral circulation.

2. *Varicose ulcers of the leg are caused* by some injury to a varicose vein; the tissues are edematous, poorly nourished, and have diminished resisting power. The injury may be very slight, but the poorly nourished tissues break down and an ulcer results. Bad hygienic surroundings and neglect are predisposing factors.

3. *Etiology of rachitis.*—Improper food, want of sunlight, improper hygienic conditions; generally, insufficient food, with the diet deficient in fats and proteins; recently, lack of mineral constituents and vitamines has been advocated as a cause of rickets.

4. *Etiology of lung abscess.*—Lobar pneumonia; lobular pneumonia; pyemia; trauma; rupture into the lung of suppuration in neighboring tissues, such as empyema, subphrenic acid, gastric ulcer, cancer of esophagus.

5. *The most probable factors in the causation of gallstones* are: Bacteria; inflammation of gall-bladder and ducts; stagnation of bile. The predisposing factors are age, sedentary occupations, and some specific fevers, such as typhoid.

6. *The diagnosis of Graves' disease* is made by the tachycardia, exophthalmos, goiter, and intentional tremor; in addition there may be widening of the palpebral fissure and failure of the upper lid to follow the eyeball when it is rolled downward.

7. *Diagnosis of psoriasis.*—The patches are chiefly on the extensor aspect of the limbs, especially on the elbows and knees; the borders of the patches are well defined; the scales are white and adherent to the crusts; there is no inflammatory exudation; on removal of the crusts red, bleeding points are visible.

8. *In spontaneous intracerebral hemorrhage (apoplexy).*—"Usually the onset is sudden, the patient becoming unconscious and deeply cyanosed. After the irritation stage, which occurs during the bleeding, has subsided paralysis of the opposite side of the body sets in with conjugate deviation, and often hemianesthesia. The muscles of the affected side lose tone, as is shown by raising the limbs. The reflexes are lost, but return with consciousness; Babinski's sign is present. The pupils vary; they may be contracted, dilated, or unequal, in which case the larger pupil is on the affected side. Various localizing signs may be present, according to the position of the hemorrhage. The temperature is normal or subnormal. Urine and feces are passed involuntarily. The pulse is full and slow and the breathing is stertorous. A lumbar puncture yields a fluid containing blood or altered blood. Within forty-eight hours of the onset the stage of reaction sets in. The temperature rises, the sphincters become normal and the reflexes return. Early rigidity, in which the muscles resist flexion and extension, may sometimes develop."—(Woodwark's *Manual of Medicine.*)

9. Râles may be dry or moist. *Dry râles* occur in bronchitis and asthma and may be low pitched snoring sounds (sonorous râles) or high pitched whistling sounds (sibilant râles). *Moist râles* are produced by the passage of the air through liquid and may be crepitant, subcrepitant, or gurgling in character. *Crepitant râles* are extremely fine and occur at the end of inspiration; they are heard in the first stage of pneumonia and in engorgement and edema of the lungs. *Subcrepi-*

tant râles are comparatively few in number and are heard during inspiration and expiration, in capillary bronchitis, pulmonary edema, hypostatic pulmonary congestion and incipient phthisis. *Gurgling râles* may be large or small and are heard during inspiration and expiration in phthisical cavities, bronchial hemorrhage, in the stage of secretion in bronchitis and over the trachea.

10. *Aortic regurgitation is diagnosed by:* A diastolic murmur heard best over the aortic area; the pulse is peculiar, being the Corrigan or water hammer pulse; the heart beat is strong and the precordium may bulge; the carotid, bronchial, and femoral arteries may pulsate violently; the apex beat is displaced outward, owing to the hypertrophy of the left ventricle.

PRACTICE AND MATERIA MEDICA.

1. (*a*) Lobar pneumonia is caused by the *Micrococcus lanceolatus* (or *Diplococcus pneumoniæ*); Friedlander's pneumobacillus is often found. Predisposing causes are exposure to draughts or inclement weather, intemperance and winter weather.

Physical signs of lobar pneumonia.—"*Inspection* reveals during the first stage deficient movement of the affected side, due to pain. The apex beat is normal in situation and the interspaces do not bulge. In the second stage the healthy side rises normally, the affected side lagging behind. If both lower lobes are impervious to air, the diaphragm cannot descend and the epigastrium does not project during inspiration, the breathing being conducted by the upper part of the chest (superior costal respiration). *Palpation* during the first stage shows the vocal fremitus to be more distinct than normal, especially over the diseased portions. In the second stage, the vocal fremitus is markedly exaggerated, except in those rare instances of occlusion of the bronchi by secretion. The cardiac impulse is felt in the normal position. *Percussion:* In the first stage, the percussion note is slightly impaired at times, having a hollow or tympanitic quality. In the second stage there is dullness over the affected parts, with an increased sense of resistance. Over unaffected adjoining areas the resonance is increased (Skoda's resonance). *Auscultation:* In the first stage there is heard over the affected part a feeble vesicular murmur, associated with the true vesicular or crepitant (crackling) râle, heard at the end of inspiration only. In the second stage there is harsh, high pitched, bronchial respiration, at times resembling a to-and-fro metallic sound, except in those rare instances in which the bronchi are more or less filled with secretion. Bronchophony, or distinctly transmitted voice, is present and at times pectoriloquy, or distinct transmission of articulated sounds, may be heard. In the third stage, the breathing changes from bronchial to bronchovesicular and the crepitant râle (crepitatio redux) returns. As resolution proceeds the breath sounds are associated with large and small moist and bubbling râles.—(Hughes' *Practice of Medicine.*)

(*b*) There are three stages: (1) Hyperenia or engorgement; (2) red hepatization or exudation; and (3) resolution or gray hepatization.

(*c*) *Treatment.*—Consists in rest in bed, milk diet and the administration of fractional doses of calomel followed by a saline in the early stage. The nervous symptoms and temperature may be controlled by applying ice bags or compresses wrung out of cold water (60°-70° F.) to the chest or by the use of the warm or cold wet pack. The heart and pulse should be sustained by the administration of alcohol, strychnine (gr. 1/60-1/20), atropine, caffeine, strophanthus, and nitroglycerin. Digitalis may also be employed. Inhalations of oxygen afford temporary relief when the dyspnea and cyanosis are extreme. In young, vigorous and plethoric adults, with hyperpyrexia and a high tension pulse, bleeding may be beneficial in the first 48 hours. Convalescence should be guarded, and tonics, stimulants, etc., will be found very useful in this period of the disease.—(*Pocket Cyclopedia.*)

(*d*) Serum or vaccine treatment is considered a specific by some authors.

2. (*a*) Children may suffer from lobar pneumonia, lobular or bronchopneumonia and hypostatic pneumonia.

(*b*)

LOBAR PNEUMONIA.	BRONCHOPNEUMONIA.
Generally a primary disease.	Generally secondary (to bronchitis or an infectious disease).
Age has little influence.	Generally found in very young or very old.
Sudden onset.	Gradual onset.
Fever is high and regular.	Fever is not so high, and is irregular.
Ends by crisis between sixth and tenth day.	Ends by lysis, at no particular date.
Generally only one lung affected.	Generally both lungs affected.
The physical signs are distinct, and there is a large area of consolidation.	Physical signs indistinct, and the evidences of consolidation are indefinite.
Sputum is rusty.	Sputum is rather streaked with blood.

The symptoms of *hypostatic pneumonia* are those of a low grade lobar pneumonia.

For *treatment of lobar pneumonia* see question 1.

Treatment of bronchopneumonia.—Absolute rest in bed and a nutritious diet; the chest should be enveloped in a thick cotton jacket; the temperature of the room should be equable—about 65° or 70° F. If the bowels are inclined to be constipated, fractional doses (gr. 1/6) of calomel are advisable every hour until six or seven doses have been taken. In the earliest stages the tincture of aconite is of service. Its action should be *cautiously* watched, and as soon as the pulse becomes soft the drug may be omitted. Usually six or seven doses are sufficient. After the second or third day its action is too depressing and is not recommended. If the temperature rises above 102.4° F. it should be reduced by means of a cold bath. Phenacetin may be given to control the temperature, but should not be used routinely. After the third or fourth day a flaxseed poultice containing mustard (ʒ 1½) may be applied to the chest and renewed every hour. After the poultice has remained on the chest about two hours give the syrup of ipecacuanha (℥ 15) every ten minutes until emesis is produced. Both these procedures should be repeated on the following day. When the poultice is removed replace it by a cotton jacket. If the heart is weak give cardiac stimulants.—(*Pocket Cyclopedia.*)

The *treatment of hypostatic pneumonia* is that of the original condition, with the addition of stimulants (such as nitroglycerin or strychnine); their position in bed is to be frequently changed.

3. (*a*) *Hookworm disease* is a severe malady in the South, characterized by profound anemia, protruding abdomen, dropsy, weakness, lack of energy, shortness of breath, and maldevelopment.

(*b*) It is caused by the Ankylostoma duodenale or the Necator Americanus.

(*c*) The ova are voided in the feces; the latter are scattered on the ground, and the ova then come in contact with the feet and hands of the poorer inhabitants, and are then conveyed to the month.

(*d*) and (*e*) Thymol is the new remedy. *Treatment (Prophylactic)*—Shoes should be worn, and proper toilet facilities should be provided. Indiscriminate scattering of fecal matter is responsible for the prevalence of the disease, and the most stringent rules should be adopted to correct this unhygienic nuisance. Flies should be excluded. *Treatment (Active)*—On the day before the treatment is to be begun the patient is advised to eat little dinner and no supper at all. Late in the afternoon he is given a full dose of calomel (2 to 10 grains, depending upon the age and strength of the patient). If the calomel does not act freely during the night a full dose of Epsom salt in hot water should be given as soon as the patient wakes up the next morning. After the bowels have thoroughly acted, finely powdered thymol in capsule is given. The dose of thymol should be divided into two equal parts, the first half being given at once and the second at the expiration of an hour. Following the administration of the medicine the patient should be instructed to remain in bed. Harris suggests that the drug should be given in the following quantities:

Up to 5 years of age,	10 to 15 grains.
From 5 to 10 years,	15 to 30 grains.
Ten to 15 years,	30 to 60 grains.
Fifteen and over,	60 to 120 grains.

In advanced age the quantity should be somewhat less than during middle life. The patient should be allowed no breakfast and no dinner on the day of treatment, a cup of coffee once or more during the day is permissible, but nothing in the nature of food. If the patient experiences no ill effects from the thymol, it is well to put off the administration of a laxative until four or five

o'clock in the afternoon, at which time some saline should be administered in hot water. After the bowels have acted well the patient may be allowed to have food. When the treatment is carried out faithfully it is rarely necessary to repeat it. It is well after a couple of weeks to again make a thorough examination of the feces, and should the microscope reveal the presence of eggs the treatment should be repeated, and this should be done over and over again until exhaustive examinations of the feces show by absence of the eggs of the parasite that all have been expelled. The public should be especially warned against patent and proprietary medicines for hookworm disease, as they all have as a basis thymol, or some other poisonous drug, and are therefore unsafe in the hands of those unacquainted with their proper use.—(*Pocket Cyclopedia.*)

(*f*) Hookworm may simulate pernicious anemia.

4. (*a*) *Acute indigestion* is characterized by: Nausea; vomiting of undigested, or partly digested, sour-smelling matter, which later assumes a bilious character; pain and tenderness in epigastrium; anorexia; sometimes severe cramps or burning pain in abdomen; temperature normal; pulse accelerated; sometimes prostration and cold perspiration. It is to be differentiated from *Appendicitis*, in which the greatest tenderness is in the right iliac fossa, and right-rectus muscle is often rigid, and a leucocytosis may be present. *Cholelithiasis*, in which the pain is paroxysmal, and is referred to the region of the right shoulder, emaciation and jaundice may be present, and there may be a history of such attacks. *Intestinal obstruction*, in which the prostration is more marked, there is absolute obstipation, tympanites, and uncontrollable vomiting which becomes stercoraceous. *Uremia*, in which a uranalysis shows albumin, and diminished urea, and the blood pressure is high.

Treatment—Evacuate stomach and bowels; give an emetic (a hypodermic of apomorphine hydrochloride) or use a stomach tube. Then give divided doses of calomel followed by castor oil or a saline. Apply heat externally to the abdomen. The stomach must be kept at rest and no food given for from 12 to 24 hours; during this time small sips of very hot water may be allowed. Later, light diet for a few days. For the vomiting, bismuth subnitrate, or creosote, or phenol may be administered.

(*b*) *Opiates* may be administered for severe pain which is uncontrolled by the foregoing remedies; but one must be sure that the case is not one of appendicitis, intestinal obstruction, or uremia. Codeine sulphate, or morphine sulphate with atropine sulphate may be given. (*c*) By hypodermic injection.

5.

ACUTE PARENCHYMATOUS NEPHRITIS.	CHRONIC PARENCHYMATOUS NEPHRITIS	CHRONIC INTERSTITIAL NEPHRITIS.
1. Most common in children, from exposure or infectious fevers.	1. Later life; often the consequence of acute attack.	1. Late life; often results from alcoholism, gout, lead-poisoning.
2. Edema of lower eyelids; then of upper extremities, trunk, and, lastly, lower extremities.	2. In early stage same as acute form; later, dropsy may diminish.	2. Dropsy slight or entirely absent.
3. Urine scanty, dark or smoky color, high specific gravity, 1025 or over.	3. Urine normal or increased amount; specific gravity may fall to 1010; urine pale.	3. Urine greatly increased; specific gravity low, 1005; urine pale in color.
4. Large amount of albumin.	4. Late in attack, greatly diminished; occasionally absent.	4. Albumin greatly diminished, often absent.
5. Variety of casts, such as hyaline, blood, epithelial, and waxy casts, also free red blood globules, and epithelial cells.	5. Large and small granular casts; compound granule cells, and fatty epithelium.	5. Hyaline or finely granular casts, occasionally dark in color: infrequently blood casts and oil droplets.
6. Urea diminished.	6. Urea diminished.	6. Urea diminished.
7. Recoveries frequent.	7. Recoveries rare.	7. Indefinite duration, but never cured.

The treatment of acute nephritis consists largely in rest in bed, warmth, milk diet, and attempts at elimination of waste products. Free purgation should be secured by means of the salines, calomel, or compound jalap powder. Diaphoresis may be favored by the administration of sweet spirits of niter, and in severe cases, pilocarpine, and by the use of warm baths, warm applications, or the vapor bath. Tincture of digitalis (♏ 5-20 every 4 hours), tincture of strophanthus, or sparteine (gr. ¼-½) may be given as diuretics. Infusion of cream of tartar and juniper berries may be employed. The occurrence of uremia will require prompt and energetic measures.

The treatment of chronic parenchymatous nephritis consists in rest, regulated diet, and the administration of tonics. The diet should be made up of milk, vegetables, rice, and a small amount of meat, fish, and eggs. Iron, quinine, and strychnine are indicated. Constipation should be avoided by the administration of the salines. Bathing and massage are important items in the treatment. Uremia may occur in this affection.

The treatment of chronic interstitial nephritis should be directed to the cause, and in addition the diet and hygiene should receive attention. The food should be largely of milk, vegetables, and fruit. High arterial tension should be controlled by nitroglycerin and aconite. The bowels should be always kept free. Diuretics are not indicated so long as secretion is free. The recurrence of uremia will require special treatment. (*Pocket Cyclopedia.*)

6. (*a*) Whatever therapeutic value radium may possess is due to its radioactivity. It has been claimed that radium emanation is of value in all kinds of non-suppurative arthritis (except luetic and tuberculous), in chronic muscular and joint rheumatism, in arthritis deformans, in acute and chronic gout, in neuralgia, sciatica, lumbago, and in tabes dorsalis for the relief of pain. Its chief value is in the relief of pain. In certain new growths, both benign and malignant, a favorable influence is exerted; so, too, in epithelioma, birthmarks, and scars. (From *New and Nonofficial Remedies.*)

(*b*) *Digitalis* is indicated in diseases of the heart: (1) When the heart action is rapid and feeble, with low arterial tension; (2) in mitral lesions when compensation has begun to fail; (3) in nonvalvular cardiac affections; (4) in irritable heart, due to nerve exhaustion. Digitalis is *contraindicated* in diseases of the heart: (1) in aortic lesions when uncombined with mitral lesions; (2) when the heart action is strong, and arterial tension high. Digitalis is also a diuretic; and it is also used in some forms of nephritis, exophthalmic goiter, pneumonia, chronic bronchitis, etc. *Dangers: Overdose or constant use* will cause irregularity of the heart, headache, vomiting; and hobbling dicrotic pulse, particularly when the patient changes from the recumbent to a sitting posture.

7. *Specifics:* (1) *Mercury* is said to be specific for syphilis; it is said to exterminate the treponema; the administration of mercury should begin early in the disease and be continued for two or three years. It may be administered by intramuscular injection, by inunction, or in combination with potassium iodide.

(2) *Quinine* is specific for malaria; a ten grain dose of sulphate of quinine should be given in the sweating stage, and again five hours before the next paroxysm is expected.

(3) *Diphtheria antitoxin* is specific for diphtheria; the prophylactic dose for children is 500 to 1,000 units, by hypodermic injection; the therapeutic dose is 2,000 to 4,000 units.

8. (*a*) To avoid salivation, give small doses of calomel, carefully watch the effect, and let the patient use a mouth-wash of a saturated solution of potassium chlorate with a little tincture of myrrh.

(*b*) The usual dose of calomel is about one grain as an alterative, or two grains as a laxative.

(*c*) Divided doses are recommended.

9. (*a*) *Castor oil* may be rendered *tasteless* by being administered in capsules; or by being floated on orange juice or strong coffee, and covered with the same vehicle.

(*b*) In typhoid, *turpentine* stupes may be placed on the abdomen, or a few drops may be given on a lump of sugar, or it may be given by enema, in emulsion.

10. The administration of quinine would differentiate typhoid from malaria. See question 7, above.

OBSTETRICS AND GYNECOLOGY.

1. (*a*) The *female internal organs of generation* are: The ovaries, Fallopian tubes, uterus, and vagina.

(*b*) *Function of ovaries:* To develop ova, and an internal secretion.

Function of Fallopian tubes: To carry ova to the uterine cavity.

Function of uterus: To receive and lodge the fecundated ovum; to retain the fetus till it is mature, then to expel it.

Function of vagina: During coitus it receives the penis; during parturition it becomes part of the birth canal; it also serves as a channel for the escape of the menstrual and other uterine secretions.

2. (*a*) *Podalic version* is that form of version in which the breech or foot of the fetus is made to present.

(*b*) *Cephalic version* is that form of version in which the head of the fetus is made to present.

3. (*a*) *Adherent placenta* is probably due to some diseased condition of the endometrium, resulting in inflammation of the decidua or placenta. The diseased condition probably antedates pregnancy. There may be partial absence of the decidua serotina, so that the chorionic villi are in direct contact with the uterine muscle.

(*b*) *Treatment of adherent placenta:* "A finger—one or two—must be insinuated between the uterus and placenta at some point already partially separated, or, if no partial separation exist, at a point where the placental border is thick, and then passed to and fro transversely through the uteroplacental junction, acting like a sort of blunt paper knife, until separation be complete. Another mode is to find or make a margin of separation as before, and then peel up the placenta with the finger-ends, rolling the separated portion toward the palm of the hand upon the surface of the still adherent part. Great care is necessary to avoid peeling up an oblique layer of uterine muscular fiber, which might split deeper and deeper until leading the finger-ends through the uterine wall into the peritoneal cavity. Should such a splitting begin, leave it alone and recommence the separation at some other point on the placental margin. It is sometimes only possible to get the placenta away in pieces. These should be afterward put together and examined to indicate what remnants are left behind. It may be quite impracticable to get out every bit, but small remnants or thin layers too firmly adherent for removal do not distend the womb enough to create hemorrhage from their bulk, and the subsequent danger of septicemia from their decomposition may be obviated by injecting warm (2 per cent.) creolin water into the uterus twice daily until everything has come away." (King's *Obstetrics.*)

4. *Symptoms of pregnancy at the fifth month:* Cessation of menstruation, quickening, mammary signs with secondary areolæ, enlarged and pigmented abdomen, intermittent uterine contractions, active fetal movements, uterine souffle, and (possibly) the fetal heart sound.

5. *Changes that take place in the female at puberty:* Development of the reproductive organs, enlargement of the breasts, hair on pubis and axilla; the form becomes rounded, the hips widen, menstruation occurs; there are certain mental and emotional changes; and "the development of those womanly beauties physiologically designed to attract the male."

6. *Severe ante partum hemorrhage* is most likely to be due to (1) accidental hemorrhage, due to premature separation of the placenta; (2) to placenta prævia.

The treatment is practically the same in each case, namely, to check the hemorrhage and promote delivery. In *accidental hemorrhage* the membranes should be ruptured and the vagina packed, or *accouchement forcé* performed; vaginal cesarean section has been employed. In *placenta prævia:* (1) Introduce one or two fingers within the os (the hand being in the vagina) and dissect the placenta from the uterine wall for about 3 inches from the os uteri in all directions, pushing it to one side if necessary. (2) Rupture the membranes, and if there is an unfavorable presentation turn the child and make the breech engage in the os; or if the head presents, forceps may be used if speedy delivery is necessary. The strength of the woman is then the main point to be cared for, and if in a reasonable time the uterus seems to be incompetent, the child may be delivered by art. In some cases of central placenta prævia, where rapid delivery is required, cesarean section may give good results for mother and child.

7. (*a*) An ovarian cyst is generally accompanied by menorrhagia or metrorrhagia, sterility, bearing-down pain in the pelvis, which may radiate to the back or thighs, hemorrhoids or constipation, frequent micturition, and various other pressure symptoms of the digestive or respiratory apparatus if the cyst becomes sufficiently large. Later on there may be the *facies ovariana*, general impairment of health, and ascites. There are no pathognomonic symptoms. The diagnosis is made by bimanual palpation and (sometimes) exploratory incision. The condition is to be particularly differentiated from pregnancy and ascites.

(*b*) The *treatment* is ovariotomy.

(*c*) No other method of treatment produces any beneficial effect.

8. An *ulcer of the cervix* presents a clear-cut border, sometimes raised and indurated, and the base of the ulcer is formed by granulation tissue; the cervix has lost some of its epithelial covering. It may be caused by irritation from pessary or discharge, chancroid infection, syphilis, tuberculosis, or malignant disease. The chief symptoms are pain, discharge, and hemorrhage. By many ulcer of the cervix is regarded as the precursor of epithelioma or carcinoma.

9. (*a*) *Menopause* is the period of a woman's life when menstrual activity ceases.

(*b*) *Metritis* is inflammation of the uterus.

(*c*) *Salpingitis* is inflammation of the oviduct, or Fallopian tube.

(*d*) *Mastitis* is inflammation of the mammary gland.

(*e*) *Menstrual cycle* is the series of changes occurring in the uterus during the interval between the commencement of one menstrual period and that of the next following.

10. (*a*) Immediately after birth the eyelids of the newborn child should be washed with clean warm water and onto the cornea of each eye should be dropped one or two drops of a 1 or 2 per cent. solution of nitrate of silver.

(*b*) This procedure will prevent ophthalmia neonatorum in doubtful cases; it will do no harm in innocent cases; and it is the first stage in treatment if gonorrheal infection is present.

BULLETIN OF APPROACHING EXAMINATIONS

STATE	NAME AND ADDRESS OF SECRETARY	PLACE AND DATE OF NEXT EXAMINATION†	
Alabama*	W. H. Sanders, Montgomery	Montgomery	Jan. 9
Arizona*	J. W. Thomas, Phoenix	Phoenix	Oct. 3
Arkansas	T. J. Stout, Brinkley	Little Rock	
California	C. B. Pinkham, Sacramento	Los Angeles

LATIN AND ANCIENT GREEK FOR MODERN DOCTORS.*

BY A. JACOBI, M.D.,

NEW YORK.

COMPLETE education means different things in different periods of history. The instruction of the Hellenic youth meant reading, writing and the acquaintance with the poets, also gymnastics, singing, music and swimming. The teaching of the sophists, such as Protagoras, Hippias and Prodikas added the necessity of the acquaintance with subjects required in daily life. That is why many teachers taught dialectics and rhetoric. Indeed, that proves that individualism is no modern innovation.

It is true Isokrates preached general culture both theoretical and practical. But the knowledge of facts was limited. That is why Lucius Ampelius, when in the fourth century, A. D., he wrote his "liber memorialis," required 31 pages only for history, geography, mythology, and astronomy.

Between the accomplishments mentioned above there was no connection such as we should call scientific. That is why writings on Greek antiquities are fascinating like the best children's books, but not scientific. The only author of those times whose history is full of philosophic thought is Thukydides, the historian of the Peloponnesian war. The only real scientist is Aristotle. Plato, charming and thoughtful, does not belong to that class. His individualism which was combated by Sokrates (as represented in Gorgias by Kallickles and in the Republic by Thrasymachos) explains the absence of intellectual and moral force required by a state which wants nerve and energy to resist the frequent invasion of enemies. In modern times the spirit of poor Nietzsche, the idol of the hysterical of both sexes in America and Europe, who was unbalanced all his life-time and finished his vacillating mind in a lunatic asylum, has often been compared with the powerless philosophy of the ancients who shone like meteors, and like meteors proved evanescent.

The scantiness of subjects taught in ancient times corresponds with the lack of connection between them. The greatest thinkers do not impress us with any multitude of known facts. Like the pupils of our own Latin schools, or the monks of our mediaeval times, they were strangers in the world they inhabited. Even the great historian Herodotus whom we all love and admire for his honesty, observation, industry, and also credulity, traced in the naiveté of his talks no philosophic connection between the stories he tells. There was no scientific link, nor a scientific plan. That is what surely and almost abruptly aided in destroying both ancient culture and political existence.

Aristotle and Galen, with a few successors, controlled the practice of doctors more than fifteen centuries. Their language either in translation or in original, was Latin. Even Bacon said he translated his essays into Latin to have them read and understood. German, English and French books written in the language of their own countries were exceptions. That is why students and scientists were drilled in Latin to be acceptable and intelligible to their peers. Particularly was that so in Germany, which at an early time controlled the opinions and teachings of scientific men. It has impressed other nations to such an extent as gradually to enforce the imitation of whatever methods were followed or said to be followed in that country. In more than its last half century that country has created the actual progress of medicine. The recognition of that fact has been the cause of our not only accepting the genuine blessings of German medicine, but also the methods of inculcating it into the schools and the preparation for them of the young men intended for its study. That has been so in America more than anywhere else. For a long time in our country learning was not common. Until late years the study in our medical schools was imperfect. We acknowledged that fact, and felt we might improve both matter and methods. The question I want you to consider is whether all our methods as long as they have been foreign imitations, are praiseworthy, and worthy, or practical.

Many of us see no progress except in the adoption of what is "made in Germany." Meanwhile, the very Germans have long become dissatisfied with what we envy them, while they acknowledge the necessity of changing or developing it. The German schools of learning had for centuries a single method of preparing the boy for the university and its professional studies. He had to run the full course of their gymnasium and its humanization preparation.

Humanistic was Latin and Greek. It was impossible to be deemed a cultured German adolescent without them. With them, and almost exclusively with them, he was declared mature. That was done when he had passed his nine classes and his examinations, about the age of 18 or 20 years. My passing them when I was much younger, was by accident, and deemed abnormal. The worst feature of that kind of instruction was the frequent absence of enthusiasm in most young men. It looks almost impossible for a dry-as-dust soul to rise to a feeling like enthusiasm for a uniform diet on Latin and Greek grammars. Of living languages nothing was taught but French, and that scantily, nothing but grammar again. Of sciences I obtained a fair amount of mathematics. Of nature history I learned by heart a few Latin names of plants, and the number of upper and lower teeth of monkeys. I hated

*Read at a meeting of the American Medical Editors' Association, New York, October 26, 1916.

monkeys and nature history. About 1870 when after a successful war the German military robbed France of 5,000 million francs, the German people threw off their agricultural habits and poverty, and delved into industry, speculation, invention, and commerce. Then lo and behold, it took only 40 years to make of Germany that wonderfully compact country of systematic progress and resourceful aggressiveness which in our era is equaled by the Japanese only, or not at all. And what has been the change on the educational fields? There is no other country but Germany in which the invasion of practical tendencies has been immediately followed by the founding of institutions of practical and useful learning. In this country of ours we are full of pride, however, with our Massachusetts, Stevens, Pittsburgh, and Chicago technical schools. Germany has scores of them. Their pupils always invaded this country of ours and our Schenectadys are glad to employ them. These young men know more engineering than Latin and Greek. Nor have the Germans, and it seems we do not appreciate that, been slow in applying their experience in other fields. While no boy of 20 could be matriculated in a university without his fill of ancient languages, in the revision of the university regulations of the 2nd of June, 1883, after the 28th of May, 1901, and the 31st of January, 1907, the Realistic Gymnasium ("real gymnasium"), with no Greek and very little Latin, but more French and English, and some knowledge of physics and chemistry, became sufficient for a young man—and lately woman also—for the matriculation amongst medical faculties.

The Secretary of the University of Rostock (Otto Schroeder) has published a book on the study of medicine in German universities, and the rules concerning examinations. On page 7 there is one, according to which a young man who has passed the upper realistic school ("ober real schule"), may begin the study of medicine without Latin on condition of his preparing during the next 2½ years a very modest knowledge of that language.

These Germans have had their eyes open for a long time and adapted themselves to their present necessities and future advantages. That makes them so efficient and preposterously successful. Other nations are slow and sluggish. We Americans have been negligent because we have been spoiled by self-esteem and by luck. The English are beginning to learn by their present ill luck. That is why at the annual meeting of the Court of Governors of Sheffield University, it was agreed in view of the great demand for physicians to give effect at once to a resolution that a knowledge of Latin should be no longer required as a condition of admission to the medical faculty. (*Journal A. M. A.*, Jan. 1, 1916, p. 47.)

Great German teachers, such as Friedrich Mueller, are not even satisfied with the sufficiency of this modification of ancient requirements, which has been acknowledged to be a progress. It is time for us that our legitimate gratitude for our old German teaching may not render us *laudatores temporis acti*, the medieval past.

Still there has been no conformity for some time in the valuation of Latin and Greek. Latin has no longer been utilized as the language of scientific writing and of clinical lecturing in England since 1765, and in German universities these 75 or 80 years. Christian Thomasius, 1655, praised French and British as a model for his German countrymen, but he dared to write in German and had the courage in 1688 of announcing a German lecture. That was in Leipzig a *crimen laesae majestatis* and became a source of much annoyance. That is why when Halle was founded, he emigrated to Halle. It was one of their greatest physicians who abolished Latin in his clinical and other lectures. That was in 1840, and the reformer was Johann Lucas Schoenlein. Still Latin and Greek were long considered the *ne plus ultra* means of methodical mind culture.

An entertaining bit of history referring to that belief you may find in the January number, 1914, of the Bulletin of the Johns Hopkins University, in which Dr. C. W. G. Rohrer, of Baltimore, published a sketch of the life and work of John Hunter. He never was a zealous student at any of his schools. His brother William wanted him to study medicine and give up surgery, that is why he wanted him to have a sound knowledge of Greek and Latin, which were considered positively required for a complete medical education, but not for surgery, which was considered handicraft, and with the exception of superior minds is at present nothing else. When I mean to flatter a mere operator I call him a doctor. At that time John Hunter was 25 years old. He refused to give up the idea of becoming a great surgeon and, as he expressed himself to Sir Anthony Carlisle, "to be made an old woman of and to stuff Latin and Greek at the university."

It is true, however, Dr. Rohrer ventures the opinion, that "such stuffing would have been of vast benefit to him, in preventing those errors of style and literary composition which so greatly disfigure and obscure his writings." To a great extent, however, we have changed all that. Most of us are of the opinion that with every decade there are coming to the fore additional mind sharpeners and style improvers which render Latin and Greek rather back numbers, or surely not first and only teachers of culture.

That general culture is what you look for, or should look for in a physician. No general practitioner should be without it. In our time the doctor has no need to be a prescription peddler or a handy mechanic; the claims of public sanitation and preventive medicine are of universal importance. I wish everybody could have listened to this year's presidential address of Dr. Vaughan and be taught or converted.

Now there are some of us, and mainly also the Council of Education of the A. M. A., who study the best methods of preparing the student of medicine for his task. In our admiration for German erudition, such as it was, we still see many of us leaning towards older German methods. To-day I meant to do nothing but to express my own doubts and hesitations. They are mine. Perhaps they are those of the young men who are preparing for their future. Perhaps the most conservative, that means reactionary, are converted. Aye, even the English! For in this society of superior physicians and teachers I felt I should meet with those whose privilege and duty it would be to pay close attention to the demands of practical medicine and the consideration of the best intellectual food for those who mean to prepare for the study of medicine.

The *New York Times* of August 3rd has the following headlines: "Education Reform Urged in England, more chemistry and engineering, besides Latin and Greek, wanted after the war. Lords consider problem. Swiss and American systems better than British, Haldane believes; German defects pointed out." If Haldane, at whom they per-

sistently sneer because he once called Germany his spiritual home, had not sneered at German defects, he would have been hissed from the stage, though he be a "member of the house of lords," which as Galton and Karl Pearson mean to prove would, if not relieved by some intermarriage, be hopelessly idiotic, at least inferior. And it is these lords who are urging reform in education. Those of us who know English history, understand perfectly why the few names of those who speak of education, are Haldane, Cromer and Bryce, just as we appreciate the persistent enmity of British politics against America from 1812 to 1861, and 1916. As usual we repay it with Wilsonian patience if not anglomania. Our present record tells us "the Oxford and Cambridge tradition of instilling a little old school learning in the way of Latin and Greek, hand in hand with a really expert knowledge of cricket and judgment of the vintage of port, are to be scrapped to make room for chemists and engineers, if the reformers have their way!" Now Latin and Greek have always been the mainstay of the education of the British who, as Haldane says, have never been ready to take up new ideas. That is why in Great Britain there are only 1,500 trained chemists, while four German chemical firms employ as many as full 1,000.

Cromer has evidently tried to console himself by pointing to the moral collapse of Germany which he says is one of the most extraordinary and most tragic events recorded in history, and to the apparent materialization of the whole national mind of Germany! He also fears lest the same deterioration would take place in England, unless sufficient attention were paid to humanistic, particularly classical, education. I may say what Cromer does not know, that this was in part the very feature of the one-sided education which was the destruction a hundred years ago of Germany which led to Jena and Austerlitz, and finally the origin of the German revolution in 1848 which was controlled by German professors. Unfortunately German evolution of the last few decades, both civic and military, which has replaced ancient by modern languages and metaphysics by chemistry, has succeeded in making a desert of Europe. Cromer adds, which is doubtful, that he learned in America that our American universities are year by year turning out an increasing store of invaluable works on classical literature. If such were true we should perhaps not be obliged to write long semi-apologetic epistles to the semi-Indian "first-chief" of Mexico.

Bryce points to the German habit of obedience as the cause of their efficiency. Let him say the English and American lack of citizenship which has cost the English hundreds of hecatombs of human victims during two years and many billions of pounds sterling, and the lack of application of science to business both in England and America.

We have no particular reason to boast of ours. The haphazardness of our politics and diplomacy and our wastefulness has not improved our people and politics. Meanwhile, Latin and Greek, little as there was, have not helped us, the absence amongst us of modern languages has been an obstacle to our American commerce, and benefited the industry and greed of Germany. We have been slow. Columbia University is slowly coming to her senses.

The *Columbia Alumni News* of May 5, 1916, confirms the filching of required Latin and Greek, as a blow to individualism, from the old Degree of Bachelor of Arts. It is spoken of as an incident in a large policy, and should not be mentioned in an apologetic vein, but as a matter of course and a proof of progressive policy.

According to R. S. Woodworth, of Columbia, in *Science* of August 28, 1914, "while discussion has been raging over the relative values of natural sciences and the classics, the student body, where free, has attached itself to modern literature, and especially to the humanistic sciences. In Harvard, according to Dean Ferry of Amherst, 3 per cent of the student registration goes to the ancient languages, 25 per cent to mathematics and science, 28 per cent to modern literature, and 44 per cent to other subjects." And Professor Hervey has found almost exactly the same proportions among elective subjects in Columbia College! It is not probable that the annual report of 1914 published by the President of Columbia University is entirely correct when he says: "The asphyxiation of Greek and Latin as school and college subjects which began a generation ago was in no small degree due to the industrious but misguided efforts of school and college teachers of these subjects." It is not the teachers and their individual influence that make history but their system. He is more correct when he adds: "It would be in the highest degree deplorable if the modern European languages were to suffer a similar fate and for a like reason."

I do not intend to make you believe that I know everything better than my peers, but I began to teach medicine in American schools much more than half a century ago and believe I know both the demands of the better part of our public and the responsibilities of those who are to be taught to prevent or to cure the ailments of the individuals and of the communities. Maybe some of you are also acquainted with my share in trying to improve our methods of medical teaching in different schools with which I have been connected. In my own time I have also participated in our many endeavors to lengthen and deepen the medical curricula, and to add to the requirements for the matriculation and the enforcement of state examinations, and whatever has added to the opportunities of giving the public such medical advisers as benefit the commonwealth, and enhancing the standard and utility of the medical profession. That is what has stimulated me to study the ways in which these two aims might best be reached. Now, I have met with very incompetent doctors who knew Latin and Greek, and superior practitioners without them. That, however, is no sound way of comparing. You do not measure the profession by individuals. The question is not one of individual superiorities, but of the influence preliminary studies may exert on the average of a useful and eminent profession. Our physicians must be better than individual prescribers or diagnosticians.

You are asked for the best method of preparing for their work all the men in the best and most efficient and most altruistic of all professions, and the questions which I hesitate to answer but propose for your consideration is whether the study of ancient languages is a *conditio sine qua non* for the study of medicine, or whether there are other means of equal or superior value in both the acquisition of a general culture and superior professional accomplishments. In spite of the routine instruction in high schools, lyceums, gymnasiums, or colleges, which was rarely interfered with, there have always been in all countries men whose opinions differed greatly from the habits of centuries.

As early as 1580 Michael de Montaigne insisted upon the use of the vernacular language as the principal study of the young student. He states in the preface to his book (March 1, 1580), that if Greek and Roman culture are the objects of the study of ancient languages they cannot be reached on account of the difficulties connected with the learning of them. For that reason, appreciating that difficulty, his father did not permit him the use of his own French language before the boy was six years old. His only language was Latin. He was taught by that experience, and also by his books, that a child may learn his mother tongue and at the same time the language or languages of his neighboring countries. In that way it would not be deemed difficult to finish one's education with the twentieth year. Montaigne is very emphatic about that. To him the time from the twentieth to the thirtieth year is the period of intellectual and moral initiative and the creative time in a man's life. It is true that the short duration of human life three centuries ago may have influenced his opinions. But in our own time a great educator, Huxley, in his lectures delivered at the Johns Hopkins University 30 years ago expressed his views as to the subjects and methods of a young student's education from a similar point of view. He complained bitterly of the inefficiency of the education of a boy in the usual curriculum of the medical schools. He was to be prepared up to his 15th or 16th year for his university courses. These ought to be the direct continuation of his previous teaching. His own language, the history of his own country and its social life, natural history, including the main types of animals and plants, and the groundwork of biology, some arithmetic and geometry would be an ample preparation for university life. In that way the medical student will save time which now has been spent on laboriously learning how to learn, and on the temptations to which the young man is exposed in his attempt at searching for a method of study.

Maybe you remember a paper of Councilman's which he published a few months ago in the *Journal of the A. M. A.* in which he compared the results of the present German with our own American method of education of the school boy; the former being more active and time saving and vastly more successful than the latter.

In this, our own country, there is a tendency to add to the subjects to be examined on and to teach in every kind of school. It is always the pupil who is examined, or to be examined, never the teacher. The system remains the same. In college, beginning courses are found in French Greek, German, and Latin, elementary courses in every science; mathematics one-half the course offered in every first-class high school; and in history a repetition of most all the work of the high school. The practice of admitting to college with conditions which enforce the delay necessitated by working up during a year or more, and losing time and systematic endeavor is bad. The *Popular Science Monthly* admits all of that in an article which emphasized the waste of time acknowledged by all the participants in a symposium quoted, viz., Harper, West, Brown, Eliot, Baker, etc. There is very little in which these experts agree. They prove their expertness to be very one-sided. A four years' course of college is claimed too long by most of them in the case of students who mean to prepare for a profession. Some, like Harper, insist upon four years, some on two before matriculating for a profession. Harper at the same time proposes the age of 16 or 17 as proper for entering college. That gives you 20 or 21 to begin a professional study which will be finished at 25 or 26 for medicine. Butler says: "Pedagogs suppose that the more time a boy spends in school and college the better. Educators know the contrary."

As I said, Huxley proposed to crowd physics and physiological chemistry into the ordinary schools. He wants the study of medicine to begin at the age of sixteen. That is the time in which memory is very active, and reflection active enough. After the thirtieth year knowledge may grow and experience increase, but the quickness of learning and imagination does not grow. Unless the principles of biology be acquired at these early years, the first university year is mostly spent in learning how to learn.

In this our country the best part of his young years is spent on preparing a young man for his life work. The very exertions of the A. M. A. are directed to prevent a medical student from entering upon practice before his twenty-seventh year. I know of no greater mistake, no graver waste of one-half of a man's life. In grafting politics we are in the habit of searching for the man higher up. Pity it should be so. But a greater pity is that we must necessarily look for the system lower down. It is the faulty system of our children's education by incompetent teachers and methods in our primary and high schools that throws away time, opportunity, and results. They do better, with all their faults, in the other hemisphere. At all events a young man with average gifts should not spend one-half of his life, the rising and ambitious and energetic half, in preparing for its second half, even if he lives up to and through it, with its duties and difficulties and obstacles.

A few historical examples of great medical or other educators may be briefly mentioned. The recommendations of their methods are not uniform or equivalent. What I am interested in is their relation to the ancient languages as part of medical education.

A few years after the Huxley lectures in Baltimore, Billroth wrote a book in 1886 on the teaching and learning of medicine. In his opinion the knowledge of Greek and Latin is indispensable, but he speaks of the grammars only. He advises the reading of Nepos, Ovid, Cæsar and Cicero, Xenophon and Homer. These are sufficient. It is remarkable to find this highly cultured man and teacher emphasizing grammar and grammar only, that time killer and a possible gate only of culture, surely not its essence.

S. Squire Sprigge (Medicine and the Public, 1905, p. 170), refers to the schedule of preliminary education as provided for by the English General Medical Council as follows:

1. English language, including grammar and composition.

2. Latin, inclusive of grammar, translation from undescribed Latin books, and translation of English passages into Latin.

3. Mathematics, comprising arithmetic, algebra, Greek or a modern language be, as advised con- Euclid, books 1, 2, 3, with easy deductions.

4. Greek, *or* a modern language.

I beg to suggest that in all probability that if Greek or a modern language be, as suggested, considered equivalent in their influence or general cul-

ture, the modern language should be preferred on account of its practical value. Moreover, every new language, ancient or modern, adds to the intellectual possession of the boy who knows it. The refinement afforded by its acquisition, though he forget it, remains a central fund with which he may work in his future life.

Now listen to Charles Darwin. He says of himself: "Nothing could be worse for the development of my mind than Dr. Butler's school which was exclusively classical and taught nothing else, besides a little ancient geography and history." Elsewhere he says: "Nobody can despise more than I do the former stereotype silly classical training." Wilhelm Ostwald emphasized the fact that our exclusively classical training takes it for granted that those so trained are taught the superiority of the culture which moved within the narrowness of the ancient languages. That culture, however, was uniform and non-progressive. That is why it reached its acme speedily and degenerated rapidly without establishing any persistent vigor in the nation so educated and trained. Natural science and the knowledge of the progress of mankind—that means history—is often liable to cause immobility.

Ostwald (Grosse Maenner, 1900, p. 88) quotes Humphrey Davey as a boy who learned little Latin, and expressed gratitude to his teachers who did not push him; and Faraday who knew no Latin at all; Robert Mayer, who was a good swimmer and runner, but one of the worst Latinists at school; Justus Liebig, who was the lowest in his class and had to be expelled; and Helmholtz who, though the son of a teacher of philology, reports that because Cicero and Virgil tired him, he clandestinely worked at optical problems during the Latin lessons. Besides he had no social gifts, was rather slow and clumsy in society, worked slowly and only while writing, his ideas came to him rather sluggishly, and frequently in sudden starts only. And still they lived to be Humphrey Davy, Faraday, Robert Mayer, Justus Liebig, and Helmholtz. On the 2d of November, 1891, his seventieth birthday was celebrated at Berlin. On that occasion he spoke of a peculiar lack of his intellect which consisted, according to his report, of an insufficient memory for unconnected subjects. This defect caused singular results which made him appear of limited comprehension in his younger years. On page 59 of Adolf Kussmaul's book of "Aus meiner Dozenten Zeit in Heidelberg," 2d Ed., 1908, the report of one of Helmholtz's lectures which proved a failure is one of the proofs of that peculiar shortcoming.

Berzelius, who was credited by his teachers with a good mind, bad behavior, and no interest in ancient languages, was the one who discovered cerium, thorium, and selenium, and found the elemental nature of calcium, barium, strontium, tantalium, silicium, and circonium.

I venture to ask: Is it advisable to believe that the scholastic narrowness of classrooms directed by teachers with narrow minds is a cause, or frequent accompaniment of genius?

One of the great financial and judicial minds of Germany about the end of the last century, Johannes Miquel, my roommate during my Goettingen year in 1849 and 1850, was as he told me the lowest boy in his class until he was 11 years old, and reputed and called an idiot, was intellectually superior to such an extent as to tempt me to tell him "you will be either hung or a minister." Forty years after, in 1890, during the Medical Congress week of Berlin, he reminded me of my own prophecies. He was then Prussian Minister of Finance. It is true, he replied at that early time: "You will finish in a state prison." He was correct; I had been in a Prussian state prison.

Alexander von Humboldt was a slow learner until he advanced to late years of boyhood.

Woehler, the first chemist to change into organic matter an inorganic substance (ammonium carbonate into urea), was a poor pupil except in chemistry. When I worked in his laboratory in 1849 he tempted me to stop medicine and continue in chemistry.

Carl Vogt, the zoologist and anthropologist, and in 1849 one of the three temporary regents of revolutionary Germany, was a bad boy and no Latinist.

Werner Siemens (Lebenserinnerungen, 9 Aufl., 1912, p. 13), the great electrician, dropped Greek and took to mathematics.

Alfred Krupp was unusually advanced in age before he scaled beyond the lowest classes of a gymnasium.

Herbert Spencer was considered bright but hated authority and rules and had no love for Latin.

Bismarck was by no means advanced in ancient studies.

Adolph Kussmaul ("Aus meiner Dozenten Zeit in Heidelberg," 2 ed. Stuttgart, 1908, by Czerny, p. 88) reports of himself: "In my worst dreams I again sit at the school desk and perspire in my vain efforts to conjugate Greek verbs."

Andrew D. White, who was educated in a classical college, when he governed his own Cornell, treated his scientific department on an equal footing with the classical. Thus there are many examples which demonstrate that ancient languages are losing their absolute predominance in the evolution of great minds.

It is characteristic of this tendency that in the University of Illinois the movement to suppress the Latin names on prescriptions is gaining ground.

In the first volume, p. 76, of the new *Scientific Monthly*, the history of Edward Jenner, by Professor D. Fraser, Harris, Ind., M.D., D.Sc., Dalhousie University, Halifax, N. S., you find the following lines: "Addresses and diplomas were showered on him, and in 1813 the University of Oxford conferred on him the degree of M.D., *honoris causa*. As he refused point-blank to pass the examinations in Latin and Greek required by the Royal College of Physicians of London, he could never obtain admission into that learned body. When someone recommended him to revise his classics so that he might become an F.R.C.P. he replied: "I would not do it for a diadem;" and then, thinking of a far better reward, added: "I would not do it for John Hunter's museum."*

W. A. Freund, as great a linguist, ancient and modern, who in his eightieth year returned to the

*When I read that I was reminded of the occurrence in the life of a smaller man. It is about thirty years ago when I was requested to apply in writing for admission to the Academy of Medicine of Paris. I replied I never applied for an honor of the kind. The answer was that Dr. M. M. of New York had done so and was a member, and my reply was that the homeopathic gentleman had no other membership or honor in America. Perhaps he was known to be seen in the waiting rooms of French colleagues of Paris; that I, however, had a great many memberships in Europe —aye, in America—but was never known to have applied for any. That is, perhaps, why I never was a member of the Academy of Paris.

anatomical studies of the upper aperture of the thorax in its relation to tuberculosis and emphysema which he had dropped on account of his professional special obligations in a German university fifty-three years before, is of the same opinion. The study of sciences, according to him, must be commenced in the high schools, so that medicine may be begun to advantage at an early age. One or more modern languages must be known, Latin and Greek swallow up time which should be spent on studies more useful which are connected with the duties of human endeavors, and furnish the same opportunities, perhaps more so, for the training of the general faculties of the brain.

Now, gentlemen, let me say, if that be necessary, why I discussed with you one of the subjects connected with the preliminary education of medical students. Fifty-six years ago, when I began my career as a teacher, the demands asked from the young man who meant to become a doctor were very few, if any. Two years were sufficient to enable him to receive his diploma and license. Before my time, the two years' curriculum was only a repetition of one, that means, in the second year the medical lectures of the first were merely repeated.

We are now taught and told that 27 years at least must be passed before the young doctor can be declared mature. A great many subjects are taught the existence of which we did not even know, and the conditions of admission to the study of medicine are more numerous and various. Whether Latin and Greek must be counted amongst them is for you to decide. For you? Surely.

You represent for me the profession of the United States. The profession has manfully fought for the progress of medical study, the improvement of the medical schools in opposition to the alleged—mostly financial—interests and ambitions of the schools, and the interests of the public at large that either suffers or is benefited by the standards of medical practice, low or high. While so doing you have not earned thanks from your beneficiaries, it is true, but are honored by the enmities of every quack and hysterical woman of both sexes and still rendered dutiful service to the sick, no matter whether it was appreciated or not. In all these matters our conscience was clear, our eyes wide open and learning expanding. That is what they are to continue. You must have noticed the tendency in the councils of the A. M. A. to purify and elevate our medical schools in that line, but it has appeared to me that the methods are not all correct. For scores of years we have learned medicine from the Germans, but we are not bound to follow the road every German student had to follow in bygone times.

You heard my statement according to which the roads that lead into the gates of medicine have been widened by the very Germans whom we are called upon by our own teachers to follow. We had better follow their afterthoughts, not the methods they have themselves given up.

The question of Latin and Greek is finally not all. As professional citizens the other question is before us all, whether we are not wasteful with our time. Huxley and Freund tell us we are. If we shall continue to waste two years or three of every studying child's life, we owe, it appears, a better system of training to our population and every profession, and every medical man and teacher such as you should enlist with those who know that easier and better and more profitable schooling will make more efficient physicians and American citizens.

NOTES ON THE DIAGNOSIS OF ABDOMINAL DISTENTION IN CHILDREN.*

By LOUIS FISCHER, M.D.,

NEW YORK.

ABDOMINAL distention as met with in infancy and childhood is not always of grave concern. In many cases, however, the underlying causes are so varied that great skill will be required in making a clear diagnosis.

Abdominal distention is met with in chronic conditions, such, for example, as is seen in Hirschsprung's disease (the chronic megacolon); in tuberculous peritonitis; in malignant neoplasms involving the kidney (chiefly sarcomata), or in hepatic cirrhosis. Abdominal distention due to cirrhosis of the liver is usually accompanied by serous effusion. The distention is uniform and not localized. Large superficial tortuous veins, due to the internal abdominal pressure, are visible. The abdomen is so tense that it is next to impossible to palpate the viscera.

Occasionally an abdominal distention due to an enlarged spleen, in which there is also enlargement of the liver and profound anemia with ascites, is noted in Banti's disease. In tuberculosis involving the mesenteric glands, the child may suffer a slight rise in temperature, in addition to faulty metabolism, and still show but slight disturbance in the abdomen. It is in this class of obscure cases that the von Pirquet skin-test may aid in solving the problem, and when in doubt I always employ the test.

When digestive disturbance exists in spite of the fact that the food requirements have been carefully prescribed, and there are no dietetic errors, such as overfeeding, other causes must be looked for. If the child does not gain in weight the stool should be examined for the presence of tubercle bacilli.

In severe rickets, where marked lordosis exists, the usual pendulous belly will be noted. It is obvious, therefore, that the spine should always be carefully examined. In Pott's disease, where there is an enlargment of the liver and spleen, marked abdominal distention will be noted.

Other manifestations of abdominal distention, of a mild or severe form, are seen in conjunction with hydronephrosis. During inflammatory conditions of the kidney we do not encounter marked abdominal distention, but later in the disease when we have ascites, the diagnosis may be more difficult. Sometimes disease of the ovaries and the uterine adnexa may be the cause of abdominal distention. But, all of these conditions are not of an immediate fatal termination.

What concerns us mostly is the distention associated with acute abdominal conditions, or with diseases adjacent to the abdomen, in which distention is a very prominent as well as a very serious symptom.

The theme for this paper has been suggested by a consideration of the following cases:

CASE I.—A female child, six years old, had a sudden attack of fever and vomiting. The temperature rose to 105°, pulse 140, and respirations 60; there was no

*Read before the Medical Society of the County of New York, October 23, 1916.

cough. There was marked abdominal distention. The attending physician diagnosed appendicitis. The marked dyspnea was attributed to pressure on the diaphgram. When seen by me there was distinct evidence of lobar pneumonia of the lower lobe. Later, on the same day, a surgeon called in consultation corroborated the diagnosis of appendicitis. An operation was performed, and a normal appendix removed. No inflammatory lesions or adhesions were found in the abdomen. The consolidation of the lower lobe continued for five days. The child passed through the crisis, had a slow convalescence and recovered. In this case the abdominal symptom of distention was so misleading that attention was directed to the abdomen and nothing else was suspected.

Among the obscurer conditions met in children with abdominal distention is typhoid fever. We do not have the classic symptoms so well noted in the adult, but we must watch for the eruption (roseola) and the enlarged spleen. We can frequently rely on the blood count as a diagnostic aid. A marked leucopenia of 4,000, 5,000, or 6,000, with a distended abdomen and swollen spleen, should be looked upon as suspicious of typhoid fever, even though we do not have a positive Widal, or a positive diazo reaction in the urine.

Swelling of the mesenteric glands is occasionally noted with distention of the abdomen. Such glandular swelling is usually caused by serous or seropurulent effusion. A case of this kind was seen by me sometime ago, in a child three years old.

In all cases of abdominal distention a rectal examination is imperative. By means of this bimanual examination we can determine many, if not all, abdominal lesions in children. Recurring vomiting, with visible antiperistaltic waves, after the ingestion of food or liquids, and irregular or deficient evacuation of the bowels, should always be a warning of an overaction of the pyloric sphincter due to hypertrophy, or it may also be the symptom of a pyloric stenosis. When suspicion points to the presence of a pyloric obstruction, an *x*-ray examination should be made. For this purpose the usual bismuth meal should be given and the case carefully studied from a radiographic point of view.

It is a difficult matter to differentiate mild or benign symptoms from those that are serious. This is so because we cannot always trust to subjective symptoms in children, and are, therefore, forced to depend on objective manifestations. The clinical expert must rally to his assistance all diagnostic aids, clinical and pathological, remembering that the prognosis is always endangered by delay.

Abdominal pains resembling colic are met with daily. If they are due to an acute intestinal indigestion the child is not in danger. This is not the class of cases that I desire to discuss with you tonight, but the "acute abdomen" with its very significant symptoms in which "watchful waiting" frequently results in death.

An occasional cause of abdominal distention, and one ending fatally unless surgical relief is afforded, is intussusception. The diagnosis is not difficult to make, but if one is in doubt the surgeon should be called in consultation. Intussusception is by no means confined to children. I have met it in early infancy, in breast-fed as well as in bottle-fed infants. The following case is instructive:

Case II.—An infant, four months old, was seen with Dr. Levinson. It had been breast-fed, but received several feedings of modified cows' milk each day. The infant seemed to thrive until it had a sudden attack of vomiting, marked abdominal distention, and a glairy, mucous discharge from the bowel. This discharge was slightly tinged with bright scarlet blood. No feces were passed for fifteen hours. Temperature was 101°, pulse 120. On rectal examination an obstruction, which was diagnosed as an intussusception, was felt. An immediate operation was advised. The family was greatly alarmed and begged to have the operation postponed until the following day. Sixteen hours later I again saw the infant and found the symptoms more pronounced. Vomiting, distended abdomen and a tumor still palpable. I again advised operation. The child was taken to the Mt. Sinai Hospital and operated upon by Dr. A. A. Berg. In this case "the watchful waiting" proved fatal for the child. I warned the parents as to the gravity of the prognosis, but they did not realize the true condition.

Tympany is found in both inflammatory and obstructed conditions. In children it appears earlier, and is much more marked than in the adult. Distention is usually absent in intussusception, but there are exceptional instances in which distention does exist. There are several symptoms which have an important bearing on the diagnosis. One should not be misguided by the statement of the mother or nurse that a distended abdomen with fever is due to a simple colic. Many a case erroneously diagnosed as simple colic has proven to be one of a strangulated gut. A thorough examination is imperative in each and every case in which vomiting, abdominal distention, and especially pain are noted. In the early stages of acute abdominal inflammatory conditions fever may or may not be present. The presence or absence of stool during the preceding twenty-four hours will aid in determining the existence of an obstructed gut. Colicky pains with tenesmus, without expelling flatus or stool, but with a jelly-like blood-tinged mucous evacuation, should always arouse the suspicion of an intussusception.

Moribund patients will sometimes recover, as the following case will prove:

Case III.—Dorothy R., seven and one-half months old, was seen by me Jan. 17, 1916, in consultation with Dr. S. Hermann. The child had received mixed feeding, breast and bottle. She was a well-nourished infant and had good hygienic care. When seen by me the infant had been ill several days, had vomiting, tenesmus and evacuations of bloody, glairy mucus without faecal particles. There was marked abdominal distention. A horseshoe-shaped tumor, extending from the cecum to the colon, was palpable. Tympanites was present, the pulse was barely perceptible, and cyanosis extreme. The child was moribund. I concurred in the diagnosis of intussusception made by Dr. Hermann. The prognosis was grave. The child was sent to the Mt. Sinai Hospital for immediate operation. The following surgical history was given to me by Dr. A. A. Berg, who performed the operation: "Abdomen opened in upper median. Exploration revealed an intussuscepted mass extending from cecum to splenic curvature of colon, which was easily reduced. The gut was entirely visible; cecum somewhat thickened and congested." The child made a complete recovery.

Case IV.—L. M., fourteen weeks old, was seen with Dr. Weinstein of this city. The infant had been breast fed for three months and was suddenly weaned. He was given a bottle of the following formula: fat, 3:50, sugar, 6:50; protein, 1:75. After the second feeding the infant showed distinct signs of colic; screamed, drew up his legs, vomited and seemed to vomit more food than he had taken. There was slight distention of the abdomen, and very active peristaltic waves were visible. Diagnosis: Pyloric spasm, possibly pyloric stenosis. No stool passed. It was decided to wash the stomach with an alkaline solution of warm water and bicarbonate of soda. The stomach was given absolute rest for one day. Later maternal feeding was resorted to. In this case the sudden change from the maternal feeding to the cows' milk feeding seemed to offend the stomach and pylorus, for the symptoms appeared after the second bottle was taken. The symptoms gradually improved and disappeared in three days. The child recovered.

Blood Examination.—Unless we are dealing with a positive condition, such as an acute intussusception, in which time should not be lost, we can always profit by having the blood examined with especial reference to its leucocyte count. A leucocytosis of

20,000 or more is always indicative of good resistance. We, therefore, gain the knowledge of the prognosis as the following case will illustrate:

CASE V.—I was called to see a child, M. W., seven years old, with a history of having been perfectly well the previous day, but complained of abdominal pains during the night. The mother took the temperature and found it normal. The child had vomited—a yellowish fluid. When seen by me the abdomen was distended, there was marked tympanites, a slight discharge of mucus from the bowel and continued nausea and vomiting. The temperature was normal, the pulse 108. The diet was restricted, the colon flushed, and warmth applied to the abdomen. In the evening the child was comfortable, the temperature and pulse did not vary, the blood count showed 32,000 leucocytes, and a polynuclear percentage of 85 per cent. The absence of stool, the persistent vomiting, abdominal distention, and the discharge of glairy mucus from the bowel, although not bloody mucus, lead to a suspicion of intestinal obstruction or intussusception. The high leucocyte count, however, suggested an appendicitis. On the second day, after a history of colicky pains during the night, I decided to have the child operated. She was removed to the Mt. Sinai Hospital and operated on by Dr. A. A. Berg. A gangrenous appendix, with a large perforated abscess, was found.

A similar case, in a child seven years old, is reported by Elliott. The blood count showed 22,600 white cells, with 91 per cent. polynuclears.

The Pulse.—An accelerated pulse should be regarded as an indication of a progressive poison emanating from some inflamed or septic focus. Thus a pulse of 100, steadily rising to 120 or 130 while the child is asleep, should be regarded as a grave prognostic symptom. A pulse rate of 100 rising progressively, in from six to twelve hours to 110 or 120, will indicate a progressive septic infection.

It is safer not to rely on the pulse and temperature alone but to have a blood examination made. If a leucocytosis is noted, then an increasing leucocytosis with an increasing pulse rate is an indication that the inflammation is spreading, or that it is more intensified, and regardless of the temperature we have an indication for an immediate operation.

The temperature is an important aid in making a diagnosis. There are many instances, however, in which a severe inflammatory condition exists and still the temperature be found normal. This is especially true in many septic conditions.

It is hardly possible to cover all the conditions, such as subphrenic abscess, hernia, affections of the bladder, ureters, kidney, liver, and peritoneum in the short space of time allotted to a paper, so I beg your indulgence if we consider only the most usual and frequent causes of abdominal distention as met with in children.

In every case of abdominal distention clinical observations must be carefully made. An acute abdominal inflammation in a child runs a very rapid course. An inflammation running a course of a few days in adults may spread as rapidly in a few hours in children. Many cases have few promonitory symptoms. We are usually told that the child had been in good health the day before, and took sick suddenly. A *sudden illness, therefore, in which abdominal symptoms appear should always be looked upon with gravity.* Careful consideration should be given to such symptoms as persistent vomiting, singultus, and abdominal distention. The presence or absence of stool is very important in arriving at a diagnosis.

Although we have marked abdominal distention with symptoms pointing to an acute abdominal inflammation we should always inspect the lungs, more especially the lower lobe on both sides, not only for consolidation but also for effusion. Abdominal distention very frequently accompanies lobar pneumonia, also pleuropneumonia. The distention disappears with the subsidence of the acute pulmonary infection. It is quite possible to have both conditions at one and the same time.

THE MANAGEMENT OF THE RECENT EPIDEMIC OF POLIOMYELITIS IN NEW YORK CITY, FROM THE NEUROLOGIST'S VIEWPOINT.*

BY WILLIAM M. LESZYNSKY, M.D.,

NEW YORK.

PRESIDENT OF THE NEW YORK NEUROLOGICAL SOCIETY.

A MEETING of the Council of the New York Neurological Society was held on October 12, 1916, for the purpose of discussing the management of the recent epidemic of poliomyelitis. Subsequently, a committee consisting of Drs. F. Tilney, B. Sachs, C. L. Dana, W. Timme, and W. M. Leszynsky was appointed to make a general survey of the field. The various clinics at which these patients are receiving treatment were visited in order to ascertain the general plan and scope of the work.

At the three large orthopedic institutions conditions varied. One, receiving over 200 patients, had a special department. But the facilities and equipment were absolutely inadequate. This was said to be due to insufficient funds. The physician in charge had few if any medical assistants, and the large number of poliomyelitis cases interfered with the customary routine. The treatment was apparently limited to braces and massage and no neurological observations were made. At another, where over 300 patients were recorded, there was no special equipment and no separate department. All were treated in the general clinic. The treatment was Social Service, braces, and massage. Although it was considered a surgical disease, the aid of neurologists was welcomed. At another over 200 children were treated daily. A special department had been organized with elaborate equipment. All received electrical examination, baking, massage, electrical treatment, and braces when required. In the older children muscle training. With all of these facilities there was no neurological supervision.

At Bellevue Hospital and Cornell Medical School they were under the cooperative care of the neurologist and orthopedic surgeon.

At Mt. Sinai Hospital and the Neurological Institute they were under the direct supervision of the neurologist.

At all of the other dispensaries where these patients are received they were sent to the orthopedic department.

As a result of these inquiries, and for the purpose of expressing our views as to the best management, observation, and treatment of this type of disease affecting the nervous system, the meeting this evening will be devoted to the subject as announced. Let me add that there should be no misconception as to its object, for it has been conceived and developed in a purely scientific and philanthropic spirit.

It is interesting to note that the poliomyelitis epi-

*Introductory remarks at a meeting of the New York Neurological Society, Nov. 14, 1916.

demic of 1907 in New York City numbering about 2,500 cases, ran its course without being discovered, until an unusual number of children with paralyzed extremities appearing at the various dispensaries occasioned sufficient comment to excite investigation. At that time the New York City Health Department being unaware of its prevalence, no official measures were instituted.

Recognizing the importance of the subject, the New York Neurological Society appointed in October, 1907, a committee to study the epidemic of that year. Its membership consisted of seven members of the New York Neurological Society, Dr. B. Sachs, chairman; Drs. L. P. Clark, J. F. Terriberry, J. R. Hunt, S. E. Jelliffe, I. Strauss, and E. G. Zabriskie, secretary; in association with Drs. L. E. La Fetra, H. Schwarz, and L. C. Ager, for the Pediatric Section of the New York Academy of Medicine; Dr. Simon Flexner for the Rockefeller Institute of Medical Research; Dr. Charles Bolduan for the Department of Health of the City of New York, and Dr. H. L. Taylor as a representative of orthopedic surgery.

Seven hundred and fifty-two cases were carefully analyzed. Their results and conclusions are embodied in a volume of 120 pages entitled "Epidemic Poliomyelitis; Report of the Collective Investigation Committee on the New York Epidemic of 1907."

This was published only six years ago and should still be fresh in the minds of the profession. It is quite evident, therefore, that the neurologist has manifested more than a passing interest in this topic.

Since then the New York City Health Department has been on the alert, and the affection was promptly classed among the "Reportable Infectious Diseases," thus resulting in widespread publicity during the epidemic of 1916, and the quarantining and control up to October 11, 1916, of 8,927 cases. It is indeed remarkable that since the advent of the recent epidemic no reference has been made to the above-mentioned elaborate report. This valuable work of the poliomyelitis committee of the New York Neurological Society seems to have been utterly disregarded or forgotten by the medical profession, and also, curiously enough, by the New York City Health Department, who materially aided in the investigation and whose representative was an active member of the committee.

Through the lack of foresight in the management of the recent epidemic an unprecedented opportunity for clinical nuerological observation has been irretrievably lost. This was, of course, a deplorable incident, for in the excitement and public hysteria during its prevalence, through the unaccountable neglect of those in official medical control of these patients, the value of cooperative neurological study was entirely forgotten or ignored. This has been shown unquestionably by the absence of any official invitation by the New York City Health Department suggesting or requesting the cooperation of neurologists, and by the omission of the names of neurologists from the lists of committees appointed either by the city administration or among those announced as the "Committee on the After-Care of Infantile Paralysis Cases."

On this "After-Care Committee," which was formed last August and is composed of 53 members, there are 25 physicians. The names of three neurologists recently appeared on the list. One, now a member of the executive committee of 15 members (seven of whom are physicians), was appointed within the last four weeks. Of the two others, one is not aware of his membership, while the other merely has the privilege of attending its meetings.

Furthermore, the New York City Health Department has given printed instructions, with lists of hospitals and dispensaries where orthopedic treatment may be obtained, to the parents of children with poliomyelitis upon their discharge from the hospitals, probably under the influence of the prevailing idea that their only requirement is the adjustment of braces. Hence, the entire medical supervision and control of these patients have been officially relegated to the orthopedic institutions, thus establishing a precedent which must not be left unchallenged. For, if the promulgation of such a doctrine be tacitly accepted without qualification or modification by the medical profession, it must inevitably lead to confusion. These remarks, however, are not made in any spirit of rivalry, nor do I wish to attempt to belittle or discredit the value of orthopedic methods in suitable cases.

It is universally admitted that poliomyelitis is a disease practically confined to the central nervous system, and that its symptomatology, such as paralysis, atrophy, and trophic changes are due to a spinal cord lesion and that its infectious origin has no direct bearing upon the subsequent developments. Therefore, in consideration of the fact that in the modern classification of diseases, poliomyelitis has heretofore been assigned to the province of neurology, such an anomalous state of affairs as above described, is indeed surprising. To say the least, it is an extraordinary procedure. But the scientific interest of neurologists in this disease of the nervous system has not abated and cannot be so easily eliminated.

In thus pointing out certain sins of omission and the unwise encouragement of a popular fallacy, it is not my purpose to assume an antagonistic attitude. That the orthopedic institutions have been placed in exclusive charge of the "after care" of these patients, seems to have been more a matter of expediency, perhaps, than of medical selection or preference. But, as this plan of organization is now well under way, there should be no serious objection to this arrangement, if it can be satisfactorily shown that these children are adequately cared for, and that their condition will be properly studied through suitable scientific observation and medical cooperation. Unfortunately, at the present time, our hospital facilities for the special care of patients with nervous disease is extremely limited. We fully realize the importance of preventive measures, immunization, and the value of laboratory research in this emergency.

In the solution of a therapeutic proposition of this magnitude, a standardization of treatment should be instituted adapted to individual requirements, and the best interests of these patients will be conserved and scientific progress be promoted by the harmonious cooperation of the orthopedic surgeon with the neurologist and pediatrist. I shall not attempt to define their respective duties in this field as that matter no doubt will be mentioned by the readers of the papers.

These disabled children should not be deprived of any advantages that may be developed from such associated service, and all available means should be utilized for their benefit.

As a sociological problem, this may be safely left to the various social service organizations whose work is recognized as of the greatest value and is admittedly indispensable.

For the last forty-four years the New York Neurological Society has stood for the advancement of the science and art of medicine in all its relations to the nervous system. To-day it is still on the active list.

The subject of "poliomyelitis" having appeared during the past month on the program of many other medical societies in this city, an expression of our views is now in order.

145 West Seventy-seventh Street.

A THEORY AS TO THE CAUSATION OF POLIOMYELITIS.

By D. W. WYNKOOP, M.D.,
HEALTH OFFICER,
BABYLON, N. Y.

Has the medical profession measured up to standard during the epidemic of poliomyelitis recently passed? How many doctors have been asked by their patients as to the causation and mode of infection of this fearsome disease, and have but shrugged their shoulders in reply?

From my experience as health officer in a community which had one of the severest attacks of poliomyelitis for the size of its population, I have formulated a theory of the disease that I believe can be accepted.

The Theory.—We know that our bodies are given immunity to certain diseases if sufficient time is allowed for the manufacture of the antibody to combat the disease. In pneumonia the crisis comes only when this has been formed. In diphtheria immunity is furnished by the antitoxin serum. In typhoid fever artificial immunity is also rendered by serum. In yellow fever there are those who enjoy natural immunity to the disease. The reason why many diseases never occur a second time is that the antibody once established for this particular disease does not wear out.

In anterior poliomyelitis our own bodies furnish this immunity if sufficient time is allowed for the manufacture of its immune body. As proof of this contention, I offer the age statistics of the State of New York (exclusive of the city) for the recent epidemic. Most of the cases have occurred in children under five years of age. The average was two years. Why should not the rest of the children of a family come down with the same disease if it is contagious (as the word is ordinarily understood) unless they have already manufactured their antibodies for immunity? We know that they are not made immune from any outside source. If immunity is manufactured within our bodies at an early age of youth where is its manufacturing plant? Poliomyelitis attacks only the spinal cord and brings about pathological changes in the anterior horns. The spinal cord is nourished entirely by the spinal fluid that surrounds it, and it should be a study from this source on which the theory of the disease must be founded.

The Cerebrospinal Fluid.—The secretion of this fluid is by the choroid plexus in the ventricles or inner cavities of the brain. The inside lining of the ventricles is composed of ciliated cells of epithelium. They help secret the fluid that is present in the ventricles and also surrounds the spinal cord in its sheath. All the lymph glands in the body undoubtedly aid in augmenting this fluid. According to the side chain theory of Ehrlich, *i.e.* that living protoplasm can be regarded as a central atom group related to which are secondary groups or 'side chains' which have unsatisfied chemical affinities, and that toxic molecules attached to these side chains produce antitoxin in the central atom group, it is quite conceivable that these ciliated cells often in youth have not developed to a point where they can make their antibody against poliomyelitis or else the lymph secretion is deficient in certain qualities. It is conceivable and likely that some will never make this immunity, and may be stricken with the disease even in advanced age.

In natural immunity against disease we have the vivid picture of phagocytosis, the lymph cells surrounding the enemy and devouring him, chemically accompanied by the alexin (undoubtedly a product of glandular secretion) or fluid which renders germ life impossible when surrounded in this medium.

At best, our knowledge of glands and their secretion is most imperfect. Certain diseases are strongly connected with the absence of certain glands; *e.g.* the thyroid in cretinism and the absence of certain properties of this gland in myxedema. A certain part of the seminal fluid of the tests is for home consumption and certain closely allied symptoms of brain and spinal cord disorder are noted when this required amount is taken away from the body by excess. It is probable that all immune substances of the body are made in the glands of the body. It is in the glands that the fluid lymph is made. It is from this lymph that we have the pointing finger of poliomyelitis. This brings us to this statement: *Poliomyelitis is a disease caused by a negation of glandular efficiency.*

Under normal conditions the cerebrospinal fluid looks like water. In composition it resembles blood minus its corpuscles and albuminous qualities. There is no protein matter found and the count of lymph cells is small.

All nerve cells are bathed in lymph. They take from the lymph what they need as nourishment and give back to it the excretions they wish removed. The lymph becomes the middleman connecting the nerve cells with the arterial blood beyond.

In poliomyelitis this function is disturbed. This is shown under the microscope by a vastly increased number of lymphocytes. There is increased pressure in the cerebrospinal fluid which is noted on lumbar puncture. The increased number of lymphocytes is accounted for by the presence of toxic germs in the secretion it is fighting against.

There are two abnormal conditions that affect the cerebrospinal fluid in a pathological way. The first is the *quantity* of the blood supply and the second is the *quality*. Our interest is only in the latter in arriving at conclusions in connection with poliomyelitis.

We find that the quality of the blood supply is altered by insufficiency of oxygen. As examples of this condition we have anemia, cretinism and myxedema (diseases that affect growth to a greater or lesser extent).

Another feature which affects the cerebrospinal fluid is an excess of normal constituents. As an example of this we have the excess of carbonic acid found in asphyxia, uremia and Graves' disease, conditions that profoundly affect the cord and brain.

As a third and most important change in the

quality of the cerebrospinal fluid we have the presence of abnormal constituents. This should be our working point in finding the causation of poliomyelitis. There are three things to be considered under this head: (*a*) Poisons produced within the body by perverted functions of organs or tissues; (*b*) Action of bacteria upon living fluids and tissue; (*c*) Poisons introduced within the body from without by food, drink or inhalation.

As examples of (*a*) we have autointoxication by albumoses, fatigue produced by muscular over-exertion producing an excess of sarcolactic acid, excess of uric acid, cholemia shown by bile in blood, phosphoruria, glycosuria, yellow atrophy of liver, and oxaluria.

As examples of (b) we have the infectious diseases typhoid, typhus, smallpox, measles, scarlet fever, *influenza* and *poliomyelitis*. I have grouped the last two together, as I believe it will be shown they are closely related in both mode of infection and epidemic tendency. In all the above infectious diseases the central nervous changes, such as coma, delirium, stupor and motor irritations, may be brought about by high fever stimulated by toxic conditions in the blood or lymph. All tissues of the body depend upon each other for health. If one suffers they all suffer.

In only one of the above infectious diseases is there a definite selective influence shown in attacking a definite site of the nervous system; this is in poliomyelitis. In this disease the cord alone is attacked and yet the site may vary, only affecting a small group of muscles of the foot or a large group of muscles higher up. Why should the toxic germ of poliomyelitis find suitable media to grow in certain interstitial spaces of the cord and not in others? According to the clinical aspect of the disease the period from real onset to symptoms of paralysis supervening is from five to seven days. This means that by the seventh day the ordinary patient has finished making his own immunity and any further extension of the toxic degeneration of nerve cells ceases altogether. Those rapid cases, in which paralysis intervenes within forty-eight hours from the presumable onset, are nearly always fatal and the groups of muscles involved most extensive. In these cases the self-immunity manufacture of alexin was absolutely overwhelmed.

Agreeing upon the selective influence found in poliomyelitis, let us consider the other known diseases that attack the spinal cord or other specialized parts of the nervous system. They are: Syphilis, *i.e.* locomotor ataxia; rabies, in the medulla oblongata; tetanus, in the fifth motor nucleus; sleeping sickness, *i.e.* stupor and paralysis; cerebrospinal meningitis; pellagra, and beriberi.

Some of these move slowly and others with incredible swiftness. In rabies, a protozoon is supposed to be the cause of the disease, and in the earliest period of its development it is so infinitesimal in size that it can go through a Berkefeldt filter. The failure to isolate the germ of poliomyelitis or have it clearly demonstrated to all under the microscope is probably due to its infinitesimal size. Its very method of infection, being borne along the highways of travel by the gentlest winds, should prepare one for what to expect in size.

In likening an epidemic of poliomyelitis to influenza, the history of the latter in 1889-1890 should be remembered. It sprang up in one of the distant provinces of Russia in October. In November it had reached Moscow. In two weeks Berlin was attacked. Paris and London had it in the middle of December and by the end of this month it was present in New York and was spreading throughout the country. Osler, writing on the types of this disease, mentions the nervous forms: "Without any catarrhal symptoms there may be severe headache, pain in back and joints, with profound prostration. Many remarkable nervous manifestations were noted during the last epidemic. Among the more serious may be mentioned meningitis and encephalitis, the latter leading to hemiplegia and monoplegia. Abscess of the brain has followed in acute cases. All forms of neuritis are not uncommon, and in some cases are characterized by marked disturbance of motion and sensation. Judging from the accounts in the literature almost every form of disease of the nervous system may follow influenza. . . . Gastrointestinal form: With the outset of the fever there may be nausea and vomiting or the attack may set in with abdominal pain, profuse diarrhea, and collapse." These symptoms are not so very unlike those of poliomyelitis.

So often have the questions been asked "Does the disease travel by air, and have climatic conditions anything to do with its spread?"

In its non-epidemic stage the germ of poliomyelitis is undoubtedly very resistant to ordinary conditions of temperature; it is perfectly willing to stay in its envelope for any number of years or seasons. To break from its shell membrane it needs continued humidity and heat. The early part of this summer was an ideal occasion for it to explode from its chrysalis and go forth on its rounds of destruction among those infants not already immune.

The summary of the theory I advance is that antitoxin molecules do exist as part of the nerve cells and glands which make the majority of children immune to poliomyelitis. Serum may carry its antitoxin molecules but to a far lesser extent. Poliomyelitis is not contagious, except to those who are not immune to the disease—to such it is both highly contagious and infectious. In epidemics of this disease the atmosphere is surcharged with invisible clouds of these germs fresh from sporadic form or a recent case. The remedy for poliomyelitis will probably be found in a non-toxic fluid that will be injected into the spinal cord by lumbar puncture at the onset of the disease or as a preventive measure during epidemics. The nature of this fluid will probably be an extract made from a mixture of healthy glands (including thymus) till the one definitely required is found.

In conclusion, I would like to state that, contrary to what I have seen in the medical press in connection with experiments on animals, it is impossible to inoculate the guinea pig with poliomyelitis. I have made exhaustive experiments to this end with the most virulent virus, injecting directly in the spinal sheath and have been unable to produce the disease. The guinea pig, as well as most other animals, is immune, and we should sooner or later be able to find from what their immunity comes.

Encephalitis Following Salvarsan Injection. — Kohrs relates the case of a man of twenty-six with secondary syphilis, who was given one injection of salvarsan and who developed no bad symptoms for two days when a chill set in. Next day he seemed in fair condition, but one day later there were clinical evidences of apoplexy, ending promptly in death. Autopsy revealed hemorrhagic encephalitis.—*Müenchener med. Wochenschrift.*

MEDICINE IN NEW YORK CITY IN THE 60'S.

"THERE WERE GIANTS IN THOSE DAYS."

By A. L. SWEET, M.D.,

GENEVA, N. Y.

At the time of which I am writing the old University Medical College building stood, according to my recollection, in Fourteenth Street not far from Union Square. It has since burned down, and I think that Tammany Hall stands upon its site. I use this institution as a nucleus around which to arrange these sketches because I was there at the time and it was the oldest medical school in the city, and also in its halls were gathered some of the great ones of our profession. This building, if it were to be described, would be characterized as absolutely without any modern improvements. There was a tradition that there was a furnace somewhere in the subterranean regions, but no one believed it, for there were never any indications of its existence. During lectures we who were there as students were obliged to wear our overcoats and arctics, and during the intervals box and jump about to keep the circulation going. One would laugh now to see such an amphitheater as we had in those days, and in the center a little old blackboard which revolved on a peg on a short post, upon which Van Buren used to write "prostrate" and tell us that that was *not* the name of the gland. This building contained among other things the museum of Dr. Valentine Mott, the destruction of which was an irreparable loss to the medical profession. In the front of the building on the front floor was a sort of reception room, where prospective students were received, and where they procured the tickets of the different professors and were registered. I may say in passing, though not in its proper place, that on the tickets of Dr. Mott there were engraved a hand with the index finger extended, and in the end of the finger an eye, a very striking and significant device. In this room frequently some of the professors would foregather before the time for lectures to begin. One morning in particular I recall that Professors Draper and Paine were present, and perhaps others I do not recall. A young lad from a small country village was there and was suffering from a bad attack of homesickness (a malady, by the way, that none of the great ones could cure—the only known cure being a railroad ticket). The racket and confusion of the city had got on his nerves and he had passed a sleepless night. He wished the college to give him back his money and allow him to go home. Professor Draper took it upon himself to calm and comfort the young man, and among other things told him that "probably God had sent him there for some good purpose." As a result the young man stayed and finished his course and graduated with as high honors as anyone in the school. The reminiscences in this article are my own as I recall them—some of the biographical and other facts taken from different sources. It is fitting that we begin these sketches with the name of John W. Draper, as he was one of the senior professors, and also because he was a very distinguished man, and known as well in Europe as in this country. He was born in England in 1811, and came to this country in 1830. After finishing his preparatory studies he took his degree of M.D. at the University of Pennsylvania in 1836. He took a prominent position as a teacher of medical and scientific subjects almost as soon as he graduated, and in 1839 was called to the chair of natural history and chemistry in the academic department of the University of the City of New York. He also lectured on physiology at that institution. In 1841 he was appointed professor of chemistry in the University Medical College, and in 1850 the chair of physiology was also added to his duties. In a few years he became the president of both the medical and scientific departments of that institution. His connection with the college continued until his death, but the time of that event I am not able to ascertain. In appearance he was not an imposing man. He was very short and rather stoutly built, and his head was so large that it gave him the appearance of being cut out of one piece. I have a good picture of him before me now, and his massive and strikingly intellectual face is as vivid in my memory almost as if I had only seen him a short time ago. He was a "shaggy" man and evidently did not spend much time before his mirror, his beard on the side of his face starting down in his neck and going up to join his hair. A little tilt to his nose gave one the impression that he might have a large sense of humor, and perhaps he had, but the numerous duties which pressed down upon him, and his constant consideration of great subjects, made him perforce a serious man. He had the leonine type of face, and looking upon it one had an impressive sense of the massive mind and soul behind it. He was a man of immense and varied activities. He not only lectured constantly and contributed to many foreign and domestic scientific journals, but at the same time was pursuing original research work in many directions. It is impossible to speak in detail of all he did, but it was said that he was of great assistance to Morse in his invention of the telegraph, and one of his discoveries led to the invention of the incandescent light. His crowning glory, perhaps, was the discovery of the process by which the human face could be photographed. Daguerre, who had the credit of inventing the picture which bears his name—although he was not the inventor, only one of those who perfected it, tried to do it, but gave it up and said it could not be done, but Professor Draper, who knew more about the chemical action of light than any other man, attacked the problem and solved it successfully. The first photograph of the human face was that of his sister, Dorothy Catherine Draper. One can imagine the feelings of Dr. Draper when that face looked out upon him from the sensitized paper. Dr. Draper was one of the most modest and unassuming of men. He would come into the lecture-room with a quiet, almost deprecating air, and when he came to his experiments would probably say, "Now, gentlemen, if I have combined these chemicals properly the result will be of a certain character," and there were never any failures. There was only one request that he ever made of the students, and that was that they would not smoke in his lecture-room. Owing to some idiosyncrasy, tobacco positively unfitted him for his duties. To be obliged to refrain from smoking was a great hardship for some of the students, but they all cheerfully complied with his request. Some of his important works should be mentioned here: His "History of the Intellectual Development of Europe" made a profound impression upon the thinking classes of the world and was translated into a dozen or more different languages. In 1865 four lectures which he delivered before the U. S. Historical So-

ciety were published in a volume entitled "Thoughts on the Civil Policy of America." I suppose that it is out of print by this time, but if our present-day statesmen could have access to that volume, they might gain some ideas which would be of immense value to them in shaping the political policy of the nation. Another volume which aroused a great deal of criticism at the time was his "Conflict between Religion and Science." I have not the space to go into anything like a review of this book. Of course there were many things in it disturbing to the orthodox Christian, but in my opinion the criticism grew out of the *title* more than anything else. It should have been called the conflict between certain churches and religion, or better still, between certain ecclesiastics who were hostile toward anything in the form of science. I have no positive knowledge in regard to the religious convictions of Dr. Draper, but the episode of the student which I related above would indicate that he had a reverent spirit and that he believed in the divine ordering of things. It is surprising in the brief time allotted to us here how much some men can accomplsh; thus Dr. Draper was distinguished as a scientist, historian, philosopher, physician.

In this connection I wish to speak briefly of the sons of Dr. Draper. There were two: John and Henry. Both were exceptionally gifted men, but I came more in contact with John and remember him better. He was altogether different in appearance from his father. He was a very handsome man with absolutely black hair and full beard. He would stroll into the lecture-room behind the old table which was covered with all sorts of chemical apparatus, with his hands in his pockets and a smile upon his face, which might express the fact that he had just heard a good story and dropped in to tell it to the "boys," and very likely he had, for the sense of humor was very largely developed in him. He would then take a drink from a tumbler which by some means always stood there, and drawing his mustache into his mouth to get rid of the surplus water, would begin his lecture with an air that seemed to say, "Well, gentlemen, this is all a joke, but we will have to go through with it, I suppose." But his lectures, as I recall them, were brilliant and fascinating, and unlike some in the building, were all too short. One day he was examining a student in chemistry for his graduation. The subject was one of the arsenical tests. At one stage of the process he asked the prospective M.D. what would be the result if we placed the glass capsule over the flame of the spirit lamp? "It would break the glass," was the naïve reply. This was too much for the risibles of the professor; he threw his head back and laughed heartily. As I recall the matter he took the place of his father in the chemistry department while he continued to lecture on physiology. He also published several works and contributed to English and American scientific and medical journals. Henry was also a lecturer in the college on chemistry (analytical) and physiology. He made at Hastings-on-the-Hudson the largest telescope that had ever been constructed in the United States up to his time. He was also the author of some books along his own line and a contributor to scientific journals. He was also an authority on the spectroscopic conditions of some of the heavenly bodies. Valentine Mott, M.D., was also a lecturer in this institution at the time of which I am writing, but it was the twilight of his great intellect. I only had the pleasure of hearing one course of his lectures, as he died in 1865. He invariably illustrated his lectures on the cadaver and his demonstrator was F. D. Weiss, a very brilliant young man who passed all his examinations several years before he was of legal age to graduate.

One striking habit of Dr. Mott's I will put down here lest I forget. One would suppose that a man who had been operating upon the human body constantly for a great number of years would be so familiar with regional anatomy that he could almost find his way in the dark, and yet Dr. Mott was so considerate of his patients that he never performed an operation of any consequence without first performing it upon the cadaver. Dr. Mott had the Websterian style of face, and his lectures were absorbingly interesting, not only because of what he brought out of the stores of his own great experience, but he had met most of the great surgeons of the world and had interesting reminiscences of them.

Dr. Mott was born at Glen Cove, L. I., in 1785. He took his degree from Columbia College in 1806, but also studied in London and Edinburgh. He held the chair of surgery in Columbia until it was united with the College of Physicians and Surgeons in 1813. As I said above, his lectures were intensely interesting, but occasionally the shadows would gather and he would wander from the subject in hand. One day he gave us an interesting talk upon flying-machines, which were just beginning to interest scientific men. One day during his lecture I happened to look across the amphitheater (and in those days it was not very far across), and saw a man who became deathly pale as the lecturer progressed. I supposed, of course, that he was not a student, but some man who had dropped in from curiosity and had seen something which he did not expect. Finally he started up the stairs, and as soon as he reached the upper level, fell like a log to the floor. Dr. Mott thought perhaps that it was someone who was trying to disturb his lecture, and he expressed his willingness to go up and thrash him on the spot. He was then 80 years of age. There is no question but Valentine Mott was one of the greatest surgeons that ever lived—taking into consideration his original work, perhaps the greatest. Sir Astley Cooper, the great English surgeon, said in regard to him: "He has performed more of the great operations than any man living, or that has ever lived." He performed operations which no other man had thought of and would not have dared to perform if he had. The following is a brief résumé of the things that he did: "As early as 1818 he tied the arteria innominata—only 2 inches from the heart—for aneurysm of the right subclavian artery, for the first time in the history of surgery. Although the circulation was supposedly entirely cut off, pulsation could be distinctly felt in the right radial artery, and the limb presented no appearance of sphacelation. On the 26th day, however, secondary hemorrhage set in and the life of the patient was speedily terminated. He successfully removed the entire right clavicle for malignant disease of that bone, when it was necessary to apply 40 ligatures. He was also the first to tie the primitive iliac artery for aneurism. He tied the common carotid 46 times and amputated nearly 1000 limbs. He early introduced an operation for immobility of the lower jaw and succeeded after many eminent physicians had failed. In 1821 he performed the first operation for osteo-

sarcoma of the lower jaw. He was also the first surgeon who removed the lower jaw for necrosis." He was also the author of several works pertaining to his own field. He literally died in the harness—I heard him lecture in 1863-4, and he must have been at that time 80 years of age. He was one of the great Americans and was the first man who won from Europe any recognition of American surgery. It seems to me that there ought to be some public recognition of his greatness—he ought at least to have a niche in the Temple of Fame.

Martyn Paine lectured on Materia Medica and Therapeutics during my stay at the College. He was one of the greatest thinkers of his time, but was a brilliant illustration of the saying that "a prophet is not without honor save in his own country," and it might also be said of him that he was without honor in his own college. He had come down from a former generation and found that medical thought had swung far away from him and left him solitary on a desolate eminence. He still believed in bloodletting in selected cases, and in the antiphlogistic treatment of inflammation. At this time all bloodletting had been consigned to the limbo of unconsidered trifles, and pneumonia, typhoid, and diseases of that class were being treated with quinine and whisky. Dr. Paine saw no reason to change his ideas in regard to the treatment of disease, but was continued in the college out of regard for his eminent character and for what he had done for the school in the past. The younger professors smiled indulgently when his name was mentioned, and, of course, the student body took their cue from them, and they would lounge into his lectures because they must come before him for exams, but frankly bored and would sometimes snap their watches if they thought the lecture was exceeding the limit. He was a tall, imposing, cadaverous-looking man, with apparently not an ounce of adipose tissue on his body. His face was pale and not mobile, but his brilliant, luminous eyes lent to it expression. Dr. Paine was the author of "Medical and Physiological Commentaries," "Materia Medica," "Institutes of Medicine," and perhaps other works. The latter volume I am most familiar with, and it is a monumental work. There is no branch or phase of medicine which is not treated in this volume. He wrote before the days of germs, but he pursued to their lairs the hidden causes of morbific action, and the intelligent reader has no difficulty in accepting his views. It is interesting to reflect at this time that he sought the ultimate causes of disease, applied his remedies, and cured his patients in utter ignorance of the germ which had caused all the trouble. After a long and studious life (he would often meet the servant coming down to light the fires as he retired to rest), he was gathered to his fathers, and as far as I know no tribute was paid to his memory.

Alfred C. Loomis began his career as a lecturer about the time I entered the university. As I recall the matter he was the last survivor of a tuberculous family, and decided that in self-defence he would study medicine and find, if possible, some new facts in regard to consumption, and in this effort he took the shortest and most direct method to ascertain the effect of the malady on the human body. He studied the cases at the bedside and when they were fatal followed them to the morgue and studied them post-mortem. In this way he became absolutely familiar with the pathological lesions of this disease (and others) which was the foundation of his fame as a diagnostician in later years. Professor Loomis, as I recall him, was a rather tall, well-built man, with very dark hair and eyes, and very white but healthy-looking skin. I am frank to say that I enjoyed his early lectures more than those of later years, when he had become a distinguished man, and his lecture room was crowded with professors and students from all the colleges. At this time the very fullness of his teaching made it difficult for the average student to appropriate it. One day he was lecturing on croup and related the following incident: He was coming through one of the streets on his way to the college when he saw a number of children playing on the pavement in front of a large residence. As he came nearer he heard one of them cough—that peculiar, croupous bark that we have all heard and dreaded. His first impulse was to ring the bell and tell the parents to care for the child, but professional diffidence restrained him and the next time that he came that way there was crape on the door. After leaving college I did not see Professor Loomis for several years. I was practising on Long Island and broke down from overwork and naturally went down to see him. After a careful examination he told me that my liver was badly atrophied and if I had any business matters to attend to I had better be about them. That was about forty years ago, and I am here writing about him, and he has long since gone to dwell in that "low green tent whose curtain never outward swings." Dr. Loomis said one day that he supposed every man must have a hobby and his own was quinine. At that time it was quite the habit of some practitioners to treat pneumonia with that drug, which was certainly contrary to all pathological teaching, and the effects of the remedy. The wife of Dr. Loomis, who died of pneumonia, was presumably treated in the same way. A few years after, by a strange coincidence, the professor himself died of the same disease. Two things impress me in this connection—before the gathering shadows shut out the light from that great brain did he congratulate himself that at least he had not died of tuberculosis, and did he order for his own treatment that which had doubtless wrought many cures in his hands. Dr. Loomis had an international reputation and was the author of a work on diagnosis, which as far as I know has not been excelled.

Just at this point there flits across my mental vision a unique figure in the professional world. Prof. "Jimmy" Wood was not one of the great ones, but he accomplished a great deal, for he began his surgical career when a mere youth. He was a miniature man with hands and feet like a lady and the habit of blushing like one of that sex. As I remember, he was connected with the College of Physicians and Surgeons. I was present at his clinic one day when he was operating for hernia. The room was full of students and professors. He explained the different tissues as he came to them and then said, "Gentlemen! the next fascia is the cremaster muscle—you will probably never see it, as it is the creation of the anatomist." He came down to Long Island to operate upon one of my patients for cancer of the antrum. After the growth was all removed he asked us to place our fingers in the upper part of the cavity. "That, gentlemen," he said, "is the cribriform plate of the ethmoid bone—I never go beyond that." As I said, he began as a youth and was operating constantly until his life went into an eclipse.

William H. Van Buren lectured at the old college

during my time. He was the most kingly man that I ever saw. Over six feet in height and well proportioned, with a fine head and face, he was a figure never to be forgotten. He lectured an anatomy and surgery, with special reference to the genitourinary organs. When he came up into the old amphitheater and made his courtly bow, there was always a burst of applause. He published one book, at least, along the line of his own specialty and perhaps more, I do not remember.

But we must stop with only a brief mention of others who were ornaments to the profession in those years, and who are worthy of a niche in the medical Temple of Fame. Charles A. Budd and Fordyce Barker, both brilliant lecturers on obstetrics; Alfred C. Post, who might be remembered as the Sir Galahad of the profession—without fear and without reproach—modest and methodical and delighting in all of what might be called the ornamental phrases of medical terminology. During my own examination he asked if an injury was on the right side of the cranium, where would the paralysis be, if any? On the left side, of course, was the answer to that question. "What is that sometimes called?" he asked. I happened to remember that it was sometimes spoken of as *contre coup*. "Yes, sir, very good," he replied, "a French term." Another unique figure in the profession was Prof. G. S. Bedford, whose specialties were diseases of women and children. In 1850 he established a clinic in the college for the treatment of those diseases, and from the time it was established to 1868 there had come before his classes more than 8,000 patients. His lectures were *sui generis*—they were witty, sentimental, poetical, and religious, and his cases were presented in such a graphic manner that one would never forget them. Many of these cases—perhaps all of them—were reported and published in a volume which is as fascinating as a novel. Professor Markoe was known as the great tenotomist, and his friends said there was not a tendon in the body which he had not cut. Professor Sayre was the great authority on morbus coxarius, and was operating almost daily.

These reminiscences would not be complete without the name of D. B. St. John Roosa, who was a contemporary of mine, and who became eminent in his specialty as an oculist. He was not only distinguished in his profession, but was a public-spirited and influential citizen and received the degree of LL.D., I think from his own college.

In looking over my notes, I see I have omitted the name of Prof. J. C. Dalton. He was not an inspiring lecturer, but he was an authority on physiology and published a work on the subject, which was used as a textbook at the college. It may be possible that there are some inaccuracies in these reminiscences, as I have written with unassisted memory—and a half century is a long time.

Case of Lipodystrophy in a Boy.—Boissonnas describes a case of this relatively new affection which has hitherto been seen to attack girls only. The patient is six years old and his trouble appeared two years before, after pertussis. The face, while its musculature is normal, is quite free from fat. This lack of fat involves the neck but does not extend further downwards. Arms and trunk have normal fat, but the notes and lower extremities show a notable increase of adipose. On account of this peculiar distribution the dystrophy is spoken of as "fatleggedness." The absence of fat in the face and neck gives a peculiar appearance to the child, whose cheeks are hollow and eyes deeply sunken. The diameter of the cheek shows that only skin and mucosa are present.—*Correspondenz-Blatt für Schweizer Aerzte.*

AN IMPROVED INSTRUMENT FOR MAINTAINING AN ORAL AIR-WAY, DURING GENERAL ANESTHESIA.

By JOSEPH E. LUMBARD, M.D.,

NEW YORK.

INSTRUCTOR IN ANESTHESIA, UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE; ANESTHETIST TO BELLEVUE AND ALLIED HOSPITALS, HARLEM DIVISION, LUTHERAN, KNICKERBOCKER, AND LYING-IN HOSPITALS.

In previous articles* I mentioned the importance of keeping a free oral air-way for certain condithesia and described my invention for that purpose. Since then I have changed the instrument, making it smaller and stronger. Inasmuch as all anesthetists fully agree, which is saying much, that too great emphasis cannot be placed upon the necessity of keeping a free oral air-way during general anestions, I feel justified in harping on my hobby and have succeeded in making a more perfect device. During the last few years numerous tubes have appeared for the same purpose made by Hewitt, Connell, Ferguson, Coburn, Flagg, and Pinneo.

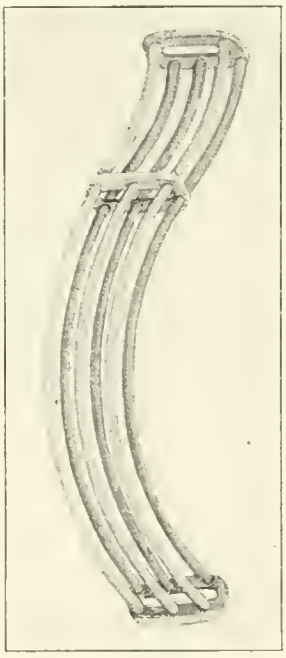

Fig. 1.—Lumbard's air-way; the lower is the pharyngeal end. Two-thirds actual size.

In the second of the articles above mentioned I call my instrument "A Controller of the Tongue and Palate During General Anesthesia." While this is possibly more correct than the new title, it is lengthy and ambiguous.

My latest instrument (see Fig. 1) for maintaining an artificial oral air-way, is constructed as follows: a double row of three curved wires running parallel, about an eighth of an inch apart, are firmly held together by three crossbands. The instrument is 4½ inches long, ½ inch in width and ⅛ inch in thickness. It contains nine pieces and is nickel plated. Properly made, it will not rust nor come apart when sterilized.

No attempt should be made to introduce this instrument until the patient is well anesthetized, for the pharynx is one of the last reflexes to yield to general anesthesia and the introduction of the instrument too soon is apt to cause gagging. The

*Helps in Surgical Anesthesia, *Journal A. M. A.*, November 23, 1912, p. 1853. A Controller of the Tongue and Palate During General Anesthesia, *Journal A. M. A.*, May 22, 1915, p. 1757.

instrument is easily introduced by inserting the pharyngeal end between the tongue and the soft palate until it rests in the pharynx (see Fig. 2). Should the respirations become noisy this annoyance can be overcome by extending the head back-

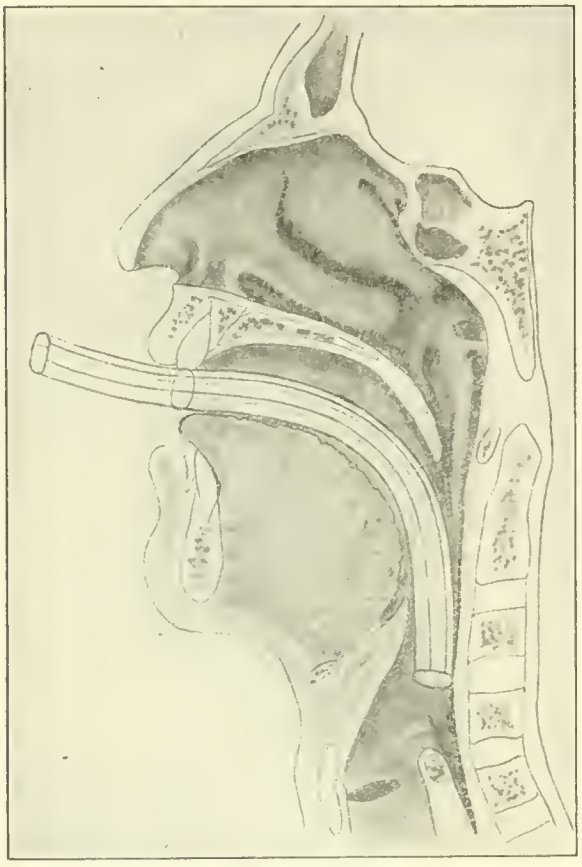

FIG. 2.—Lumbard's air-way in situ.

ward. Sometimes the noisy breathing, when the tube is in situ, is indicative of a light anesthesia. In such cases it is better to take the tube out and deepen the anesthesia before replacing it. A few cases will do better if traction on the tongue is made before the air-way tube is introduced; in such cases do not use the tongue forceps, but always make traction with a piece of dry gauze held between the fingers. A swollen tongue from crude instrumentation will often cause the patient more trouble than the operation itself.

The instrument does not interfere with any face mask nor with any method for administering a general inhalation anesthetic. Not only does this air-way obviate the task of holding the jaw forward, but is useful in the aged where the lips obstruct the air passage.

I have often noticed when instructing interns and students that they are quick to see and appreciate the advantages of this instrument. I would earnestly recommend the use of this tube in all abdominal operations, especially when in the Trendelenburg position; also when there is any obstruction to free respiration during anesthesia. Keeping the instrument in situ after the operation, until swallowing returns, will greatly hasten the recovery from the anesthetic. I consider an instrument for maintaining an artificial oral air-way one of the most important items of an anesthetist's outfit.

A free oral air-way is indicated in the following conditions: When there is (1) cyanosis due to obstructed nasal or oral breathing; (2) unrelaxed muscular condition, due to faulty breathing; (3) enlarged tongue or falling back of the tongue, especially when the patient is in the Trendelenburg position.

When using the insufflation method or oxygen, a rubber tube can be easily attached to the side of the instrument by a rubber band or string. (See Fig. 3.)

The insufflation method and oxygen can also be used with Lumbard's vapor mask, with the air-way tube in situ.

The substitution of free oral respiration for imperfect nasal or oral respiration will, in a great majority of cases, immediately be followed by slower and quieter breathing, improvement in color, and greater muscular relaxation; in fact, a much improved type of anesthesia is the result.

The following are the advantages of this tube, each of which removes several disadvantages in similar instruments: (1) It will not clog with mucus, thus eliminating the chief defect of other instruments. (2) It is easily and quickly inserted. (3) It is easily kept in position, whereas the weight of a solid tube often displaces it. (4) It cannot be compressed by the teeth and gums. (5) It will not conduct a fluid anesthetic to the pharynx, an accident liable to occur with other tubes. (6) It may also be used on children as well as adults. (7) It is quickly cleaned and sterilized, because it is open

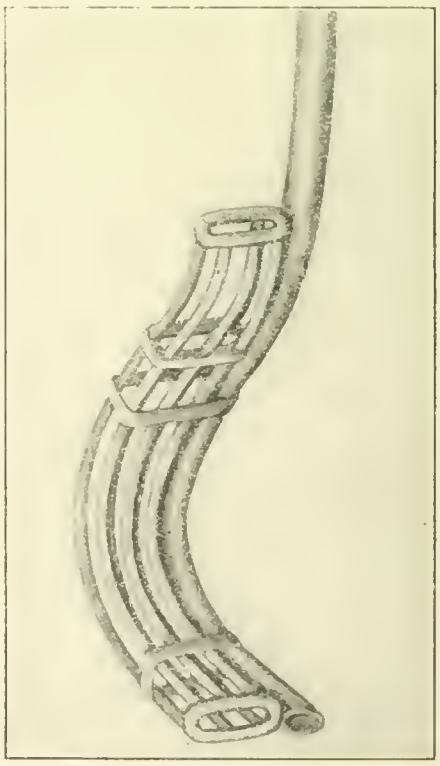

FIG. 1.—Lumbard's air-way with rubber tube attached for the insufflation method or oxygen. Two-thirds actual size.

on all sides. This tube has well been called the "sine qua non" of the anesthetist.

1927 SEVENTH AVENUE.

Action of Salvarsan.—It is certain, according to Eliasberg, that salvarsan may be toxic and fatal and that we are unable either to foresee or prevent this toxicity. Abortive treatment, so-called, only renders the disease latent and cannot justify marriage. Salvarsan is only a treatment of symptoms, while the intermittent and chronic use of iodine and mercurials should cure the disease.—*Dermatologisches Centralblatt.*

REPORT OF THE COMMITTEE ON INDUSTRIAL HYGIENE OF THE RETAIL DRY GOODS ASSOCIATION.

By MORRIS H. KAHN, M.D.,

NEW YORK.

ONE of the vital desiderata in the maintenance and progress of an industry is that the health of the individuals concerned in furthering it shall be at the highest possible standard.

Some industries and the city departments, and some members of the Retail Dry Goods Association (Bloomingdale Brothers, Lord & Taylor) have undertaken a method of medical supervision which calls for periodic examination of every individual in their employ. Through routine examination of the employees of various department stores we have been able to discover cases of kidney and heart disease, cancer, diabetes, and quite a number of cases of pulmonary tuberculosis. These diseases progress insidiously for a number of years and affect the efficiency of the worker. By the time the employer feels obligations to the employee for length of service, the disease incapacitates him completely. He is put on the list of dependents or pensioned, or for months money is spent vainly to help him when the entire occasion was avoidable.

About 10 per cent. of the applicants for employment in one store (John Wanamaker) were affected by tuberculosis.[1] Another store revealed twenty-four cases of pulmonary tuberculosis with physical signs in the first thousand consecutive examinations of its employees, and in another were found four cases of advanced tuberculosis with positive sputum in the first 250 examinations made.[2]

It frequently happens that epidemics in department stores are averted by the isolation of a case of infectious disease, such as diphtheria, scarlet fever, etc. In one department store (Bloomingdale Bros.), the incidence of acute infectious diseases during 1914 and 1915 were as follows:

	Jan.	Feb.	March	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
1914												
Acute follicular tonsillitis	15	18	24	12	2	1	3	2	..	..	1	10
Acute rheumatic fever	3	2	..	2	1	..	..	..	..	..	..	..
Diphtheria	1	1	2	..	2	1	..	..	..	..	..	..
Pneumonia	..	..	1	..	..	..	..	..	..	..	..	..
Influenza	14	4	9	1	..	..	..	..	..	..	..	1
1915												
Acute follicular tonsillitis	4	7	6	8	9	5	4	1	2	..	..	6
Acute rheumatic fever	1	..	1	1	1	1	1	1	..	..	..	..
Diphtheria	..	..	1	1	1	..	..	..	..	..	..	..
Pneumonia	..	..	..	..	..	..	..	..	1	..	..	..
Typhoid fever	..	..	..	..	..	..	..	..	1	1	..	..
Erysipelas	..	..	..	..	..	..	..	..	..	..	..	1
Malaria	..	..	..	..	..	..	1	1	..	1	..	..
Influenza	5	1	5	5	1	..	..	..	..	1	..	19

Each case required at least one week of absence from work. But for the prompt isolation of the cases of diphtheria, tonsillitis, etc., as they occurred an epidemic would have been inevitable. At one time the shoe department of another store was almost entirely depleted by the spread of acute follicular tonsillitis. When the smallpox epidemic was threatened, those department stores having physicians promptly undertook vaccination, with a consequent security which was comforting and healthy; and they served as subsidiary health centers for advocating also vaccination against typhoid fever.

In those stores from which the employees go for one week during the summer to a cottage provided and paid for by the employer, physical examinations were made of each applicant. In one store during 1915, 203 applicants were examined especially for pediculosis capitis, skin diseases, throat and lung diseases. Leaflets dealing with the eradication of pediculosis, "colds," tuberculosis, general hygiene, etc., were distributed among the applicants.

Prevention by sanitary measures and early recognition of disease are the great aims of medical supervision. In the several industries employing a physician, he is on the premises for a varying number of hours during the day, and examines and treats the medical and minor surgical cases. When found ill and with fever the cases are sent home and instructed to stay in bed. Throat cultures are taken in all suspicious cases. Exact treatment is outlined until the following morning and the patient is advised when able to consult the family physician. If the patients are better the following morning and return to work they are seen then. If still ill, they report the fact, after which they are visited and advised, according to their need. When necessary, the patient is referred to the proper hospital and arrangements are made for admission. Cases requiring dispensary care, as for test-meals, *x*-ray examinations, etc., are sent to the proper clinics. One store has granted leaves of absence for this purpose to employees on pass from physician, without deducting the time. (Bloomingdale Bros.)

When we live or spend any part of the day among a community affected by conditions and diseases which are infectious and communicable, we are taking the risk of the spread of the infection to our own selves. It is to the advantage of the conscientious employer to protect his employees and the public. We cite this merely because the danger has called itself to our attention repeatedly.

A nurse recently discovered a girl with syphilis working among other girls in the office of one store. She had active signs of the disease with an eruption on her skin and sores in her mouth. It happened to be an office in which no sanitary drinking cups are installed, adding to the gravity of the situation. When such a state of affairs is possible once, no too great precautions can be taken.

With the rapid and splendid advances made by the Department of Health in our municipal administration, there is only one way to keep apace with them, or our sanitation and scientific methods of industrial supervision in department stores will become an anachronism and a menace, rather than an asset. The Department of Health some time ago inaugurated physical examination of cooks and waiters of all the restaurants and public dining rooms of this city, to establish their freedom from an infectious or venereal disease in a communicable form. When a department store takes such matters into its own hands, through the conscientious interest of its own physician, it demonstrates a regard for the public welfare which is highly commendable, and profitable from a commercial standpoint. In one public dining room a physician noticed a lesion on the finger of a waiter, and, upon investigation, it proved to be an early and very contagious stage of syphilis.

A prolonged sickness is often avoided by timely attention. In one store (Bloomingdale Bros.) where this is constantly enjoined by the physician in short daily talks to the employees, there has been a remarkable reduction in the weekly number

on the sick-list. This reduction is, in great part, attributable to these talks. During 1914 and the early part of 1915 there was a weekly sick-list of 13 to 28, with an average of 19 each week for the first four months of 1915. The number on the sick-list fell to from 2 to 12 each week, with an average of 5 each week for the last six months of 1915, a reduction of more than half the number. The talks were given among a fluctuating audience of employees during their lunch hour, and the physician noticed the greater number of early cases of "colds" and infections seeking his attention, which previously came when the condition required rest at home and an absence from work of one to six weeks. Thus immediately a great deal is saved by such a provision in the medical administration of our stores.

It is essential for each department store to have a physician to advise and direct the sanitary side of the problems which arise in the course of time. Having a physician and a graduate nurse in attendance is necessary from the standpoint of custom. When customers faint or are injured in the store, the presence of the store physician, or of the store nurse, gives the customer security of prompt medical attention.

The presence of a nurse among the employees is an educational advantage as well. Cleanliness and appearance and personal hygiene are habits which it needs training to acquire. One amazing fact alone stands out convincingly in favor of medical supervision. Of 150 girls examined in one department store (in 1915) approximately 75 to 50 per cent. showed vermin in their hair, visible without deep scrutiny. A customer buying at a counter where he or she noticed such a condition would certainly hesitate to buy there again. But a nurse can keep insisting all day upon eradication of such a condition. A crusade is being conducted in one store by the physician with some success through the distribution of a circular of instruction with that regard.

In the same store in 1916, it is noteworthy that of 220 girls examined, only 32 or 14.5 per cent. showed pediculosis, in marked contrast with last year's statistics.

During the winter season in every department store a number of applications, written or verbal, are received from employees requesting aid. Insufficient food, lack of supply of coal, and sickness figure as factors in the conditions. The only way to learn of the exact conditions existing is by systematic visits made to the home of the employees. This can best be done by the store nurse. The nurse can also discover the underlying factors and causes of these conditions in the families—such as alcoholism and drug habituation; large families of minor dependents, mental deficiency, ignorance, lack of ambition, disease, etc. The nurse can do the great part of the welfare work in the store.

A medical department is, therefore, an unquestionable necessity for each store. It may be made practicable even for two stores to divide the services of one physician. We therefore recommend the employment of a nurse or doctor or both as a part of the running force of every department store and every factory having more than 250 people in its employ on stationary premises.[3]

This would mean the setting apart of a room in which employees might be treated. On the basis of the broad experience of its members, the committee suggests that such a hospital be adapted as economically as possible to meet the real needs of the employees, and that the money expended be put into service first, rather than into over-elaboration of plant.

In machine shops and factories, where heavy machinery is used, a well fitted up operating room is an essential part of the factory hospital. One doctor testified at the American Public Health Association that he had amputated a leg in his factory hospital, and performed many other serious operations. These conditions, however, do not obtain in the department stores. According to Dr. Kristine Mann, who has done such excellent work with the Department Store Education Association, records show the percentage of cases to run something as follows, varying, naturally, with the season of the year or other changing conditions: Minor surgery, 37 per cent.; indigestion, 7 per cent.; colds, 17 per cent.; headache, 9 per cent.; dysmenorrhea, 6 per cent.; eyes, ears, throat, 8 per cent.; unclassified, 15 per cent.

An analysis was made of the numerical data of diseases as they occurred in the Bloomingdale Bros. Department Store during 1914 and 1915. The cases were accurately recorded daily and reported every month.

Classification of Diseases.	1914		1915	
	Number.	Per Cent.	Number.	Per Cent.
Acute infectious diseases, including tonsilitis, diphtheria, typhoid	134	9 6	106	9 3
Alimentary tract, including mouth	229	16.5	187	16.4
Respiratory tract, bronchitis, etc	186	13 7	190	17
Tuberculosis	4	0 3	6	0.5
Circulatory system	13	1	4	0.3
Skin diseases, not including pediculosis	229	16.5	173	15
Nervous diseases	69	5	62	5.5
Eyes	57	4	63	5.5
Ears	32	2 2	29	2.5
Genitourinary and gynecological	71	5	45	4
General diseases, diabetes, chronic nephritis, anemia, etc	30	2.3	4	0.3
Diseases of bones, muscles and joints	60	4 2	38	3 3
Minor injuries and infections	269	19.5	233	20.4
	1383	.....	1140	.....

The most striking feature of this table is the remarkable parallelism in the percentage of the various diseases during both years.

When an employee feels ill during the day, the administration of some medicine at the time, or that combined with rest in bed for half an hour or an hour enables the employee to continue efficient for the remainder of the day, whereas otherwise much time is lost with expense to both employer and employee.

To care for these cases, the store that can afford the space should set apart a suite of five rooms: A waiting room, a small doctor's office, a small sterile room for dressing slight wounds, and two "wards," where men and women, respectively, could lie down or be put to bed. If the store cannot give up this amount of room, the work could be begun with a waiting room and hospital, the hospital beds being properly screened. Such a suite should not be called a hospital, but better a dispensary, infirmary, or rest room. The more informal the atmosphere of the place can be kept, the less nervous the employees will be, and the more it will be used by the people.

In a series of examinations conducted by the Department Store Education Association on about 200 women, discovery was made of the fact that department store women are pretty bad physical

specimens. Their chief defects of body were found to be bad posture, functional curvature of the spine, incoordination of muscle, or body rigidity. If these conditions were eliminated or decreased, no one can estimate how great would be the improvement in feelings and symptoms. The lives of the women outside the stores showed a great need of free out-of-door (or in-door) exercise. What they get in the store, in badly constructed corsets and high-heeled shoes, behind the narrow confines of a counter, is negligible.

The committee, from a knowledge of the lives, desires, and physical needs of the department store women, would urge that in planning this health work emphasis be laid on the constructive side of it with the possibility of introducing, as part of the welfare work, as Dr. Kristine Mann has so forcefully advocated, evening gymnasium classes—partly recreative, partly for health.

No matter how diligently and conscientiously an individual applies himself to duty, an added stimulus is rendered by an expression of personal interest by the employer. And to provide medical attention for the employees is an incentive which finds its echo in their gratefulness, appreciation, and efficiency. The committee feels assured that the results will be remarkable and progressive, and will more than justify the slight expense of the introduction and running of this proposed supervising and educational system.

OBSERVATIONS OF TETANUS WITH REPORT OF A SUCCESSFULLY TREATED CASE.

By L. SEXTON, B.S., M.D.,
NEW ORLEANS, LA.
LECTURER ON MINOR SURGERY, TULANE UNIVERSITY.

Tetanus is an acute infection caused by the tetanus bacillus of Nicolaier (1884) and Kitasato (1889), usually following some wound or abrasion. Tetanus is characterized by tonic and clonic spasms of the voluntary muscles. While it is usual for some traumatism to precede the attack, it is not always possible to discover such wound or abrasion, but it should be remembered that the infection may take place within the alimentary canal (being abraded), or from some subcutaneous injury becoming infected through the blood (rarely), or from an undiscovered wound. Tetanus has at times been almost epidemic in certain hospital wards and in portions of the tropics supposed to be due to the action of the warm climate and manure mixed in the stable and garden soil, favorable to the development of the virulent tetanus organism. The bacillus is anaerobic, a facultate, saphrophyte, capable of continuing its development outside the body tissue. It is an almost constant part of the soil of the garden, stable, and dairy pens, and it is on this account that laborers, negroes, stable and dairy attendants are the most often attacked by the disease. It should also be remembered that such laborers are least careful about keeping trivial wounds aseptic. The hygienic surroundings, as well as habits of such people are generally bad. The reason they suffer from tetanus more often than other people is explained by the fact that the tetanus bacillus is normally found in the dung of cattle and other warm-blooded animals; hence their liability to infection through contact. Before asepsis was thoroughly understood the death rate among infants in poorer white and colored families was very large, during the first two weeks of infant life, from so-called "nine-day fits." The cord in many cases was severed by the midwife's rusty septic scissors, tied with a dirty thread, wrapped with an uncleanly rag, and often greased with non-sterile applications. Hebrew surgeons say that the deathrate from trismus was more frequent than it should be, before the rabbis were taught to be more aseptic with the Mohel and after-treatment of circumcision. It is our personal opinion that all such operations in the interest of child conservation should be done by doctors and dressed under the direction of nurses who have been thoroughly drilled in aseptic surgery.

Many cases of tetanus have been produced in the present European war by explosives and the contact with stable and garden soil in the trenches of Belgium, France, and Galicia, and other countries, especially in the highly cultivated districts of these countries. Early experimenters found that if garden mould or soil was placed in an abrasion or under the skin of the animal, tetanus would follow.

Kitasato in his studies could not isolate the germ until he heated the pus to 80 deg. C. for one hour to get rid of the other septic microbes, as tetanus is nearly always a mixed infection. The tetanus, like the anthrax bacillus, is very resistant to heat. The tetanus bacillus develops in the wound in long delicate threads, breaking up into separate bacilli with spores at one end, resembling the head of a pin. It is next to impossible to recover the tetanus bacillus from the original wound of infection, though the cerebrospinal fluid taken from the patient and injected into an animal will readily produce the characteristic tetanus convulsion. The tetanus bacillus always remains in and around the original wound, while its toxalbumin are absorbed into the system through the motor nerve tracts; so it is a pure toxemia, not a germ, traveling along the motor nerve tracts. The tetanus bacilli are independent of oxygen, of low vitality, and invade only bruised or septic tissue. As the germ develops in the septic wound, toxic bodies are produced, going direct to the spinal cord and brain, resulting in the tonic spasms which are characteristic of the disease. The toxin is said to be four hundred times more poisonous than strychnine, to which it is similar in pathological action.

There is no doubt about the fact that prevention of tetanus by proper disinfection of all wounds and immunizing doses of antitetanic serum is far better and safer than the treatment of the disease after it has developed. Tetanus cases have been reduced by 75 per cent in the United States since the doctors and the public have been educated to a saner Fourth of July and Christmas, and the necessity of proper disinfecting and sterilizing of all wounds as soon as received. All punctured and lacerated wounds should be enlarged and relieved of all foreign bodies by instruments or by pouring into them a warm 50 per cent. solution of hydrogen peroxide in order to remove the deeper and smaller particles driven into the tissue. Equal parts of tincture of iodine and alcohol are more suitable to these wounds than are the antiseptic dusting powders, which do not so thoroughly penetrate the wound. The application of a 20 per cent. phenol solution followed immediately

by alcohol to neutralize it, is an almost sure way of destroying the bacillus. All lacerated wounds should be thoroughly cleansed, drained, packed and allowed to heal by granulation. Out of sixty thousand wounded during the present war in Bavaria, seven-tenths per cent died, four-tenths per cent of these died of tetanus, regardless of the prophylactic injection of serum; hence the necessity of using all other legitimate preventive measures, including Bier's hyperaemia. The mistake is in giving just one dose of antitetanic serum and stopping when it should usually be repeated within from seven to ten days in order to make assurance doubly sure.

Removal of all foreign bodies, cleaning, opening, and draining of all wounds has been a routine measure at our clinic for the past ten years; the result has been fewer cases of tetanus to treat in the great Charity Hospital of New Orleans from the clinic, though many more wounds have been treated during that decade than in previous years.

The later is the development of the disease, the fewer are the spasms, and the more chronic is the course, the better is the chance for recovery. When incubation is under ten days the mortality usually reaches 60 per cent. When it is over ten days and the course of the disease runs three weeks, it is denominated chronic tetanus and the mortality is from 20 to 40 per cent. If the period of incubation and the course of the disease are both three weeks in duration, 70 per cent may recover. Lacerated and punctured wounds in which foreign bodies have been driven, furnish the best medium for the development of tetanus, for the germs are anaerobic, and are partial to saphrophytic wounds. Gunshot wounds, compound fractures, and the puerperal state are also favorable to the development of tetanus. Occasionally hospital wards and neighborhoods seem to be infected, the contagion being spread by actual contact through contaminated dressings, instruments, etc. The suspected wound should be disinfected not once, but twice daily, for it must be remembered that the germs remain in and about the wound where it was first received and that it is only the toxin which is generated several days after the wound is made, that is absorbed. There are no symptoms of tetanus manifested until the toxins have reached the spinal cord. Irritation of the motor nerve tracts causes the tonic convulsions to begin. Muscle cramps and girdle pains are due to the irritation of the sensory nerves. The extensor muscles always overcome the flexors, hence the head is retracted, feet extended, and back arched (opisthotonous). Tonic spasms are continuous except when relaxed by heroic doses of sedative drugs, which have to be kept up throughout the attack. The spinal cord is in such a state of excitability that any noise, draught, or jarring causes painful spasms to occur. Asphyxia may be threatened by tonic convulsions of the chest and throat muscles. Often the inexperienced surgeon is taken off of his guard as to the seriousness of the attack on account of the clear mind to the fatal termination. Other prominent symptoms of tetanus are retention of the urine and constipated bowels, rigid muscles, including the abdominal ones, with no sleep without heavy drugging. The first symptoms of tetanus are difficulty in mastication, spasms of the jaw, with rigid neck and abdominal muscles. When the face muscles are involved, a sardonic grin is produced that is peculiar to the disease. The violent muscular contraction with the absorption of the toxin produces high fever and sweating, which is usually persistent to the end of the case. The patients usually suffer a great deal from girdle pains around the waist produced by spasms of the diaphragm.

We should endeavor to keep the bowels well open and the skin and kidneys active in order to eliminate as much of the poison as possible. The irritability of the spinal cord should be controlled by large alternating doses of sedative medicines, including chloroform, to control the spasms. We prevent the toxins entering into the system by thorough disinfection of the original wound. We inject two thousand units of antitetanic serum in the vicinity of the wound or between the wound and the spinal cord. If the wound is upon the hand use the serum in the arm or near the brachial plexus. If in the foot, use it near the sciatic nerve. Ashhurst and Johns prefer chloroform to ether in order to relax the spasms, as it is more easily administered, but it is five times more lethal in its effects. Meltzer of New York recommends twenty minims of a 20 per cent solution of sulphate of magnesia to be injected into the spinal cord to relax these spasms. Eighteen cases so treated resulted in four recoveries; two were acute and two chronic, showing a death rate of 70 per cent, which was about the same mortality as under treatment by other methods. Irons recommends from three to five thousand units of antitetanic serum intraspinally and ten to twenty thousand units intravenously as soon as the disease is diagnosed. The earlier the treatment is begun the more favorable the prognosis of the case. After these heroic dosings on the fourth day, he again uses ten thousand units subcutaneously. We think the alternate use of syrup of chloral, bromide of potassium, morphine, and atropine should be the way in which sedatives are given to control the convulsions of tetanus. Daumsler of the French Army used six grams of chloral every six hours until the spasms were relaxed. Wintraud says that little can be expected from the serum treatment, that its use is preventive and not curative. Sainton cured six patients out of twenty-two by injecting 40 c.c. of a 2 per cent phenol solution twice daily subcutaneously. It has been found that phenol is less toxic by injection than by the stomach. Johns and Ashhurst depress the functions of the spinal cord by from thirty to sixty grains of chloretone given in either oil or whiskey. The bowels should be kept open daily by some mild purgative or enema. You may expect retention of urine, which is very common on account of the spasm of the cut-off muscle. Intraspinal injection of fifteen hundred units of antitetanic serum is the best and quickest way to apply the remedy to the over-excited spinal cord. The same amount of spinal fluid should escape before the antetanic serum is injected. In the nourishing of a case of tetanus rectal or nasal feeding may become necessary. When it is impossible to get the food into the mouth on account of the spasms of the jaws, a tooth may be extracted to facilitate the introduction of nourishment.

The following is a report of a case of recovery following tetanus:

Mrs. C., age thirty-five, mother of two children. She had never had any serious sickness before, was attacked by all the classical symptoms of tetanus, and the diagnosis was made accordingly. The only abrasion that could be found upon her person was an ulcerated hemorrhoid from which she had suffered for the past three weeks with impacted feces. The jaw-closing tonic and clonic spasms increased daily as did the temperature, when it became necessary on the fourth day to control the spasms by chloroform and sedatives in large and increasing doses. We darkened the room by

curtains, forbade visitors, ensured quiet, and protected the patient from draughts. Although we pushed the sedatives to the limit, the patient would be attacked by spasms as soon as the doses were reduced or given at longer intervals. In the early period of the disease we obtained eight vials of 1,500 units each of antitetanic serum, which we administered in the flank, two each day until they were all used. We discussed the use of the serum intraspinally, but on the principle of "safety first" for the patient, we injected into the flank and deltoid; this we commend to others in serious cases as they at least subject the doctor to less criticism if the case should prove fatal, as it is liable to do. We nourished the patient on milk, broths, soups, and various liquid foods (she swallowed best when under the influence of sedatives). We kept the bowels open with purgatives or enemas, used milk instead of water to quench the thirst, as it served the purpose of nourishment at the same time. When the temperature would reach 104°, she was given one 5-grain dose of acetphonetidin or acetanilide compound, not to be repeated more than twice in twenty-four hours, provided the temperature again reached 104°. The woman finally recovered.

As to whether this patient was benefited by the injection of the antitetanic serum as a cure, or whether the antiseptic treatment of the hemorrhoidal ulcer or unloading the impaction, or the alternate use of the sedatives, nourishing food, keeping the bowels open, or whether nature cured the case in spite of our efforts, I leave to the medical association to judge.

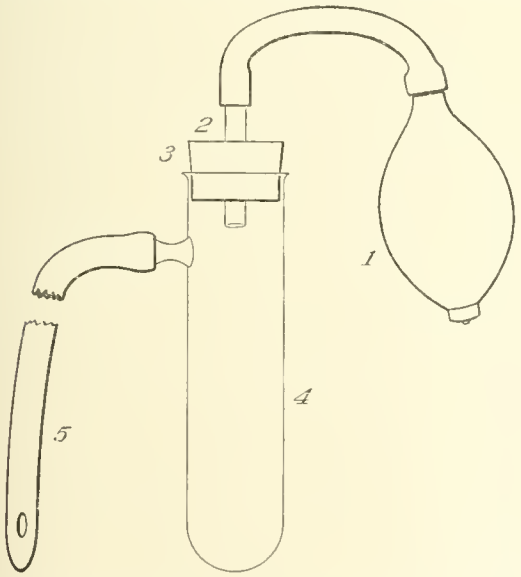
A GASTRIC ASPIRATOR.

By WILLIAM GERRY MORGAN, M.D.,

WASHINGTON, D. C.

I would like to describe here a little apparatus which I have used for fifteen years, which does all that any other appliance, such as that described by



The gastric contents evacuator. 1, aspirating bulb; 2, glass connecting tube; 3, perforated rubber stopper; 4, large test tube with side spout; 5, stomach tube.

Dr. P. A. Sheaff in a recent issue of the *Journal of the A. M. A* does, costs but a few cents, and can be carried to the homes of patients; it may well form a part of a doctor's emergency outfit for aspirating the contents of the stomachs of patients who have swallowed poison. This apparatus consists merely of a test tube an inch and a half in diameter and six inches in length. It has the usual round bottom; an inch below the open end is a glass spout; a rubber bulb aspirator, a perforated rubber stopper, through which passes a glass connecting tube, and an ordinary stomach tube complete the apparatus. The method of use of my aspirator is quite simple. The bulb aspirator is attached to the glass tube in the rubber stopper which is in turn inserted into the test tube. The stomach tube is connected with the spout of the test tube and is then introduced in the usual way into the patient's stomach. The aspirator bulb is squeezed and the contents of the stomach at once are drawn into the test tube.

One of the advantages of this apparatus over any other, aside from the small cost, is the fact that there is so much elasticity in the degree of vacuum produced in the glass container as greatly to reduce the danger of injuring the mucosa. Another advantage is that the patient is told to himself hold the container, which in a measure distracts his attention to that phase of a very disagreeable procedure which, in a nervous individual, is of no small help.

1624 I Street.

Medicolegal Notes.

When Use of Books to Contradict Medical Expert Is Improper.—In an action for personal injuries sustained in a panic following a burst of fire from a street-car controller a medical witness for the defendants, basing his opinion on his experience, testified that the plaintiff could not have suffered epilepsy as the result of the accident in question, saying, "Fright does not produce epilepsy." The plaintiff's attorney, after having identified through the witness a book on nervous diseases written by Professor Starr, asked whether Professor Starr did not say in his book that "about one-half of the cases of epilepsy is caused by fright." Questions to the same import were repeated and so framed as to appear to be statements of what was contained in Starr's book. The plaintiff's counsel then exhibited the book to the court and jury, and stated that he proposed to show by it that such contrary opinion was stated. It was held that the allowance of this constituted reversible error.—Mann vs. Blair, 195 Ill. App. 254.

Statements to Physician—Expert Evidence.—The Circuit Court of Appeals, Seventh Circuit, holds that unless it clearly appears that the plaintiff's description to a physician to whom she had gone of her subjective symptoms was made solely to aid an expert to give evidence on the trial in an action for her injury, and not in good faith to assist him in diagnosing her case for purpose of treatment, it is admissible, though the weight to be given it by the jury may be slight. If there is no conflict in the evidence as to the manner of a plaintiff's injury, it is not improper to permit a physician to state that the accident did cause, and not merely that it might have caused, the injury.—Chicago Rys. Co. vs. Kramer, 234 Fed. 245.

Fees of Young Practitioners.—In an action by a physician against an estate for services rendered the testatrix for some disease of the brain, the nature of which even a post mortem examination did not clearly determine, it appeared that the plaintiff was a young physician who had been an old friend of testatrix. The trial judge allowed the claim of $1,500 only to the extent of $262, being of opinion that a young practitioner has no right to charge, or expect to be paid, the fees charged by those who are older and whose reputations have been established. On appeal, the Louisiana Supreme Court said that it may happen that the knowledge of the schools goes beyond that upon which reputations have been founded, and that the later graduate, bringing, with his diploma, the latest discoveries, is more competent to deal with a particular case than the earlier, with the experience of a past generation. However that may be, the court held that any physician has the right, in the absence of a custom of his own, to charge for his visits, day or night, at least the fee sanctioned by the custom of the community in which he lives; nor is he obliged, in so doing, to rate himself below the class to which, in his opinion, he properly belongs; and in such a case, the burden rests upon the patient who refuses to pay to show a better reason for such refusal than that the physician is comparatively fresh from the seats of learning. The amount to be allowed was increased to $1,500, the amount claimed.—Succession of Percival, (La.) 72 So. 467.

TREATMENT OF SYPHILIS OF THE NERVOUS SYSTEM.

THAT small group of disorders formerly known as the parasyphilitic affections of the central nervous system, which included tabes dorsalis and paresis, for a long time offered successful resistance to the efforts of the therapeutists. Tabes especially was made the object of numerous methods of treatment some of which achieved a little brief notoriety, but all eventually were discarded as valueless. The recognition of the essentially syphilitic nature of these conditions and the demonstration of the presence of the spirochete in the nervous tissue placed their pathology on a sound basis. The advent of salvarsan found the profession beginning to realize that the cerebrospinal fluid offered a rich field for investigation, and experience with meningitis had shown them that intraspinous medication was at times extremely efficacious. Making use of all the information which had been yielded by such research, Swift and Ellis developed a technique for the intraspinous administration of salvarsan and obtained results in the treatment of tabes and paresis which had not been approached up to that time. Since the publication of their work there have been numerous papers written on the subject. The technique has been modified and adapted and altered and the method has been praised or condemned, often in no measured terms. Unfortunately conclusions have been drawn at times from insufficient data and an unbiased and critical observer might have some difficulty in obtaining from the literature a very clear idea as to the true value of this method of treating this group of conditions.

It is, therefore, a pleasure to see the report of the cases which have been treated at the Peter Bent Brigham Hospital during the past three years, which is presented by Walker and Haller (*Archives of Int. Med.*, 1916, xviii, 376). The report concerns forty-eight cases of tabes dorsalis, six of general paresis, sixteen of cerebrospinal syphilis, and five of syphilitic meningitis. There were given 450 intraspinal injections of salvarsanized serum and 350 intravenous injections of salvarsan. The authors divide their cases into three groups. The first group consists of patients who received salvarsan only by way of the vein. Of these only those whose infection was comparatively recent showed any definite improvement. Those patients whose infection was of long standing showed practically no benefit, so far as their nervous symptoms were concerned, from intravenous injections. In group two are collected those patients who received salvarsan into their veins and also salvarsanized serum intraspinously. In most of these cases the improvement was definite and steady. The cell count of the spinal fluid approached or reached normal and the Wassermann became either negative or less strongly positive. At the same time there was a marked abatement in their symptoms. Fifteen of these patients have been observed for a sufficiently long time to determine whether the treatment has a permanent effect. Four have relapsed and four died. The other seven have remained without symptoms for at least eighteen months. Fifteen other cases in this group have shown improvement, but the interval since the end of their treatment has not been sufficiently long to determine the end result. The third group comprises seventeen cases in which the Wassermann in the blood serum was negative, while that in the spinal fluid was positive. These cases were treated only by the intraspinous administration of salvarsanized serum. All of these patients improved. One shows a relapse in ataxia and a second still suffers from headaches. The remainder have been free from symptoms for periods varying from two to twenty-four months, seven of them for more than a year.

Patients are, therefore, treated according to this rule: If satisfactory results do not follow three or four intravenous doses of salvarsan, they are given salvarsanized serum as well. If the serum Wassermann is negative they receive only intraspinous salvarsanized serum. Following this rule the results are seen to be most excellent. There are, of course, some relapses and a few of the patients react so severely that the treatment may be impossible and it is not possible to say that any of them are permanently cured. Nevertheless, the majority show marked improvement and many remain without symptoms for comparatively long periods of time. Certainly the disease may be considered as arrested at least. Equally satisfactory results were obtained by Fordyce in the series of 180 cases of tabes, paresis, and other forms of cerebrospinal syphilis, reported in the MEDICAL RECORD of September 30. In most of these cases the Ogilvie modification of the Swift-Ellis method was used and proved itself to be as satisfactory as, and in some respects superior to, the autosalvarsanized serum method. The results are noteworthy and deserving the serious consideration of the whole profession. Certainly no patient with one of these conditions should be denied a serious trial of this treatment. The technique is not essentially extremely difficult, and while much better carried out in a hospital, can, if necessary, be done elsewhere.

PHARMACY IN RUSSIA.

THE Russian government lately appointed a committee to inquire what native plants were available as sources of those medicinal substances of which the empire stood in need. (*Pharmatsevticheski Journal*, p. 76, 1916.) Chemists and pharmacists have addressed themselves to this problem, and the

result is that there are now several published classifications in the Russian Codex of Russian plants which may be applied to the practical purpose of supplying the drugs and galenicals that had previously been imported. In most cases these drugs are identical with the foreign, while others are very good substitutes and imitations. Before the war Germany was the chief producer of alkaloids and synthetic compounds, and was able to export its surplus of coal tar, benzol, and toluol to Russia as well as the finished products of its coal tar industry, salicylic acid, salol, antipyrin, and the series of antiseptics which Russian markets took on terms most favorable to Germans. As a Russian writer in *Industry and Commerce* pointed out, it was somewhat difficult for the Russian manufacturer to succeed under a tariff in which there was a wide disproportion between the duties on raw and on finished products. Raw materials, as a rule, paid higher duties, and this is the reason, to a great extent, why Russia has fallen behind in the more modern chemical manufactures and industries. In these circumstances the Russian manufacturer could not make a new drug sufficiently cheaply to compete with the German.

Now the Government has taken the matter up, and during the past six months, the resources of the country in medicinal plants have been studied and a useful series of galenicals prepared. Pharmacists have found out, not only that such plants as digitalis, *Aconitum napellus, A. orientale, Veratrum album,* rhamnus, are plentiful in the Caucasus, Bessarabia, and the Crimea, but that they yield, in many cases, an unusually high proportion of the substances to which their active properties are due. From *Aconitum orientale* for instance, the chemist Kourrote extracted as much as 2.207 per cent. of crystallized aconitine. Similarly, from *Veratrum album,* growing in Bessarabia, he obtained 0.84 per cent. of jervine. It is in some of the plants of the Caucasus that, in Russian opinion, the resources of the country show their real greatness, the richness in plants that, for want of a better word, may be described as truly medicinal, the plants in which the healing and the chemical properties are in happy equilibrium, in which the therapeutic compound is formed on the recipe supplied by Nature herself to the investigating chemist. Many instances are given in the report of the government pharmacist, Mouschinski. Among these plants are *Pimpinella saxifraga, polygonum, Senecio crucifolius, Althaea officinalis, Fœniculum officinale,* digitalis, *Rhamnus frangula,* Russian male fern, menyanthes, and geranium. Preparations of all these are to be found in the new Pharmacopeia.

It is a different story as regards alkaloids. The war has greatly increased the demand for these among all nations and, as a consequence, the output of the sole country on which Russia could now rely, England, has nearly all been used for the latter's own needs. Russia is thus deprived of her source of supply, and incidentally offers the American chemist one of his greatest opportunities. He can profit, if he will, by the exclusion of Germany, the chief manufacturing source of the rarer alkaloids. There will be keen competition with England later, but in the meanwhile, the manufacturer in the United States should take this chance. Besides this, America and Russia have natural advantages, such as climate and soil favorable to growing plants. England, in spite of every effort, has made no great progress in the manufacture of alkaloids. With a reduced staff in her laboratories and a limited supply of labor, the conditions are decidedly opposed to the contrivance of new processes. And, as regards synthetic drugs, the war has nearly exhausted the supply. Many of these are not manufactured in England. They are now produced in Russia, but high prices and the cost of freights and of delivery hamper Russia. When atropine costs on the British market 170 shillings an ounce, the most interesting commercial facts for pharmacists is how to profit by such prices, which may be either in finding new processes or in developing the sources of natural supply.

CARE OF CHILDREN IN THE ELEMENTARY SCHOOLS OF GREAT BRITAIN.

Owing to the falling birth rate and to the slaughter of adults in the war, Europe is naturally paying more and more attention to the preservation of child life. This is especially the case in Great Britain, where the birth rate has declined, and is declining, and where men, on account of the war and of emigration before the war, have been decreasing in number at a somewhat alarming rate. A report issued recently by Sir George Newman, president of the Local Government Board, is, in the circumstances, a particularly depressing document, and will doubtless bestir the British public to efforts with the object of bettering existing conditions. The report in question points out that there are 6,000,000 children in the elementary schools of England and Wales. Of these, 1,000,000 are in bad physical condition, and 250,000, or thereabouts, are really too ill to learn. These are startling figures, and Newman's analysis of the situation is interesting and valuable, in considering not only English school children, but the school children of this country. The U. S. Public Health Service is at the present time investigating the health of rural school children in parts of America, and the result of their investigations so far has been almost as discouraging as the English report. The writer of the report places the blame for the deterioration of English children on the rearing of children prior to school age, but chiefly upon school life itself. For disease and defects in the child leaving school are some reflection on the influence exerted upon it during its nine years or so of school life. As the report notes, it is not easy to escape the deduction that if the child, on entering school, is ailing, it is part of the business of those responsible for its ultimate equipment to seek to improve its physique both before it comes to school and during its school life; and if the leaving child is unfit for employment and citizenship, the system of its education stands, in greater or lesser measure, condemned.

It is most assuredly undeniable that education, while primarily designed to equip the mind, must provide also for the body's needs. The ill-nourished, unhealthy child cannot absorb knowledge properly, and even if it could it would be at the expense of

its physical powers. It is a means of draining vitality which augurs ill for the future of a race or nation. Child power requires as much attention as man power, and Newman suggests as the sole reliable safeguard a complete scheme of education, physical as well as mental, by the state.

Epileptic Myoclonus.

It has often been stated that one case thoroughly studied has far more educational value than a digest of a lot of loosely observed material. This is especially the case with little understood affections. A case by Wolfer in the *Correspondenz-Blatt für Schweizer Aerzte*, August 26 is one in point. This disease appears notably in degenerate stock and the author is fortunate in being able to record the family history. As there were several cases in the family, we are reminded that the familial type is very common and severe. The father was a strenuous drinker and also had tabes, the mother being healthy. It is of interest that Bührer reported the case of the elder (female) in 1901. The father's father and mother's mother were both alcoholics in association with marked psychic degeneration. The sisters' epilepsy began at 12, myoclonus at 14. In addition to the brother's case, a sister is known to have had fits. She died of pneumonia. Two more brothers, healthy in Bührer's time, are still living and well (now aged 25 and 23). A sister living at 20 had a doubtful history of partial epilepsy in childhood. According to Bührer the case was one of partial epilepsy with complete unconsciousness. Thus of 6 cases, 4 were surely tainted as a result evidently of crossed inheritance. Study of the author's patient was negative. A piece of pectoralis muscle showed no evidence of myopathy. There was evidently a heightened muscular tonus, a heightened mechanical excitability of the muscles and complete absence of sensory disturbances. The nervous system was unstable, and the intensity of the contractions was dependent on the state of the psyche. The author believes that the inferiority of the patient's constitution was manifested chiefly in the muscles and parts of the nervous system, both central and peripheral. Treatment was of no avail. As Lundborg exhausted the subject of familial myoclonus-epilepsy many years ago, but little can be added that is new, but 4 cases out of 6 children in a family should be almost a record.

Treatment of Whooping Cough by the Krauss Vaccine.

According to Paranhos, of Sao Paulo, Brazil (*Brazil Medico*, September 30), an epidemic of pertussis appeared in that city in the early months of 1915 which attacked children with unprecedented severity. At the University Polyclinic all sorts of treatment laid down by classical writers were given a trial. It was learned from an article in the *Semana Medica Argentina* that a vaccine was prepared and used in that country with excellent results. Following the published directions, the author had the vaccine, designated originally by the name of Krauss, at once prepared both for private and clinical work. It was tested on a material of 49 cases, of which 28 were in the early stages, 17 between the second and fourth week of the disease, and 4 after the fourth week. The technique of Krauss, which consists essentially in the use of increasing doses, was closely followed. In the early cases there was marked improvement in respect to cough and vomiting in the great majority. After the second inoculation the accesses diminished in frequency and severity. In the more advanced cases the response to treatment was less pronounced, or rather more slow, but benefit was apparent after repeated inoculations, and the duration of the disease was cut short. As far as this epidemic is concerned, the vaccine may be regarded as decidedly the most efficient treatment.

News of the Week.

Death Rate in New York.—For the week ending November 11, 1916, the death rate in New York City was 12.28, representing a total of 1,315 deaths, as compared with a rate of 12.63 and a total of 1,324 deaths for the corresponding week of last year. Seven deaths from poliomyelitis were reported during the week; and there was a decrease in the deaths to contagious diseases, diarrheal diseases, cancer, tuberculosis, and diseases of the nervous system, and an increase in the mortality of heart disease, lobar pneumonia, and Bright's disease. The death rate for the first 46 weeks of 1916 was 13.96, as compared with 13.91 for the corresponding period of last year.

Dinner to Health Official.—Mr. Eugene W. Scheffer, secretary of the Board of Health, New York, who retires at the end of this year, was the guest of honor at a dinner given at the Yale Club on November 15, about 150 guests participating. Addresses were made by former Commissioners Goldwater and Darlington, Dr. William H. Park, Dr. Robert J. Wilson, and others. Mr. Scheffer entered the Department of Health as assistant chief clerk in 1895 and became secretary in 1902.

Resolutions of the New York Neurological Society.—At a meeting of this society held November 15, the following resolutions were presented by Dr. Walter Timme and unanimously adopted:

Whereas, Anterior poliomyelitis and its concomitant polioencephalitis are intrinsically neurological diseases, and

Whereas, Anterior poliomyelitis and polioencephalitis have been managed in all stages in the recent epidemic practically without the supervision and control of neurologists in the institutions of Greater New York, and

Whereas, In order to avoid faulty diagnosis, inadequate treatment, and poor methods of gathering important statistics, resulting not only in detriment to the present patients but also in a final loss to scientific medicine of valuable data of great service in future epidemics; be it

Resolved, That it is the sense of the New York Neurological Society that anterior poliomyelitis and polioencephalitis being neurological diseases, the sufferers from such diseases ought at an early period to come under the care or supervision of neurologists, with the cooperation of orthopedists and other specialists as the cases may require. And, in consideration of the unprecedented number of cases in the recent epidemic, in all public institutions and clinics where these diseases are treated, there should be a standardization of equipment and method. And be it

Resolved, That the New York York Neurological Society petition the Committee on Public Health of

the New York Academy of Medicine that it consider the advisability of appointing at once a commission on poliomyelitis which shall take into consideration the ways and means best calculated to meet and combat a future epidemic similar to the one we have just experienced and make definite recommendations for same. This commission shall consist of four subcommittees, as follows: (1) A committee on communicability and quarantine, comprised of bacteriologists and epidemiologists. (2) A committee on the criteria of diagnosis and clinical management, to consist of neurologists, pediatrists, and orthopedists. (3) A committee on pathology and serology, to consist of pathologists who shall devise the best means of caring for such pathological material as is obtained as a result of the epidemic. (4) A committee on treatment and immunization, to consist of neurologists, orthopedists, pediatrists, and bacteriologists. This committee shall consider the therapeutic means best adapted to the acute stage and also to the after treatment.

Physicians to Germany.—Difficulties in transportation may force the abandonment of the plan to send six American physicians of German descent to Germany and Austria-Hungary for six months, to care for civilians in those countries. The State Department is now endeavoring to obtain guarantees of safe conduct from Great Britain, but it is doubtful that these will be forthcoming. It is said that $16,000 has been raised in Philadelphia to pay the expenses of the trip and the salaries of the doctors.

Anti-Heart Disease.—The Association for the Prevention and Relief of Heart Disease was recently incorporated in New York for the purpose of working for the prevention of heart disease through the dissemination of information and the application of recognized preventive means. The association proposes to gather data, to study and develop occupations and vocational guidance for cardiacs, and to assist in the establishment of cardiac classes. The officers of the association are: Dr. Lewis A. Conner, *President;* Dr. T. Stuart Hart, *Vice-President,* and Dr. N. L. Deming, *Secretary.*

Changes at Cornell.—Dr. W. Gilman Thompson, professor of medicine in Cornell University Medical College since the founding of the college in 1898, has resigned his chair in order to devote his time entirely to his private work, and has been appointed professor emeritus. The vacancy thus created has been filled by the appointment of Dr. Lewis Atterbury Conner, who, has been connected with the department of medicine at the college since 1898, and since 1900 has been professor of clinical medicine and in charge of the medical instruction at New York Hospital.

Harvey Lecture.—The third lecture of the present series of the Harvey Society will be delivered at the New York Academy of Medicine, 17 West Forty-third Street, on November 25, at eight-thirty, by Dr. Paul A. Lewis of the Henry Phipps Institute for Tuberculosis. Dr. Lewis will speak on "Chemotherapy in Tuberculosis."

The Seventh District Medical Society of North Carolina will convene at Monroe on December 4 and 5. The society has a membership of over two hundred and it is expected that the majority of the members, as well as a number of invited guests, will be in attendance.

The Harvard Hospital Unit.—Six surgeons, a dentist, and twenty nurses sailed from New York on the *Andania* on Tuesday of this week to join the Harvard Hospital Unit at a British base hospital in France. They will take the places of an equal number whose term of service expires on December 9. Since the organization of the unit in June, 1915, 117 surgeons and dentists and 184 nurses have been in the service.

Additional Gift to Chicago.—Announcement has been made of the gift of $500,000 from Mr. Julius Rosenwald of Chicago to the University of Chicago, for the proposed new medical school. As previously announced, the Rockefeller Foundation and the General Education Board have given $2,000,000 for the same purpose, and the remainder of the money necessary is to be provided by the University of Chicago and by private subscription.

London "Times" Red Cross Fund.—The London *Times* on November 15 announced that its collections in behalf of the Red Cross had passed the $25,000,000 mark.

Blockley Ex-Resident and Resident Physicians.—The thirtieth annual banquet of past and present internes of the Philadelphia General Hospital was held at the Hotel Rittenhouse on November 11. Dr. B. Franklin Stahl presided, and Dr. Herman B. Allyn acted as toastmaster. Addresses were made by Dr. J. Chalmers Da Costa, Dr. Joseph Sailer, Dr. Charles B. Kendall, Dr. Randle C. Rosenberger, Dr. D. J. McCarthy, and Dr. Wilmer Krusen.

Association for Advancement of Science.—The sixty-ninth annual meeting of the American Association for the Advancement of Science, and the national societies affiliated with it, will be held in New York during the last week of December. An attendance of more than 2,000 is expected.

Memorial Tablet.—A bronze tablet in memory of Dr. Abraham Mayer has been placed in Lebanon Hospital, New York, the dedication taking place on November 19.

Removal.—Dr. W. A. Bradley has removed from 55 West Seventy-fifth Street to 127 West Seventy-fifth Street.

Heroine Addicts Increasing.—At a meeting of a committee of judges, physicians, and others, organized to fight the drug habit in New York, recently, the statements were made that heroine addicts are becoming so numerous in the city that the city hospitals and institutions must enlarge their facilities greatly if they are to deal successfully with the cases turned over to them by the courts; that ninety per cent. of all drug victims are enslaved to heroine; and that while the drug-store sales have been cut 75 per cent., smugglers of the drug still keep the sidewalk dealers supplied.

Fake Salvarsan.—The recent indictment in Newark, N. J., of two men engaged in the traffic has revealed what appears to be a widespread conspiracy to defraud the Government by smuggling salvarsan and neosalvarsan into the United States. Still more serious is the discovery that these men had also in their possession a large quantity of spurious salvarsan, which, on examination, proved to be either starch or table salt. These spurious products, it is believed, have been offered for sale throughout the country, and, as they are contained in ampoules closely imitating the real product, many physicians have been deceived. In order to stop the sale of this fraudulent salvarsan it becomes incumbent on any physician having any information on the subject to communicate with Chief Inspector E. R. Norwood, U. S. Customs House, New York, or, in case of emergency, with the local police authorities.

Health Insurance.—A conference on social insurance, to be held in Washington from December 5 to 9, 1916, has been called by the International Association of Industrial Accident Boards and Commissions, an organization of the official bodies charged with the duties of administering compensation laws in the United States and Canada. An interesting program has been arranged under the four headings of Workmen's Compensation, Sickness Insurance and Benefits, Invalidity and Old Age Insurance, and Social Insurance Applying Especially to Women.

Accuracy of Poliomyelitis Diagnoses.—The Weekly Bulletin of the New York Department of Health for November 18, 1916, contains an answer to the assertion that the recent epidemic of poliomyelitis in the city was largely a creation of the Department, and that a considerable number of the cases listed as poliomyelitis did not belong in this class. Of the 9,418 cases occurring during the epidemic, 4,474 were treated in the Department's hospitals; of this number, 96, after observation, were discharged as no illness, and in 49 additional cases the illness proved to be other than poliomyelitis. This means that actual mistakes in diagnosis occurred in only 1 per cent. of the cases. Again, out of 2,715 cases followed in their homes, 1,885 were found to have a serious paralysis, and 530 a partial paralysis, of one or both legs, and 273 a total paralysis of one or both arms. These figures, in the opinion of the Department, bear ample testimony to the high degree of diagnostic accuracy attained during the epidemic.

Opportunities in Civil Service.—The New York Municipal Civil Service Commission will shortly hold an examination to fill vacancies in the position of junior alienist in Bellevue and Allied Hospitals. The salary of the position is $1,200 per annum, with advancement to the position of chief alienist with a salary range of from $3,780 to $4,680 per annum for full-time service.

The Commission also offers an opportunity for a man desiring to fit himself for industrial corporation work in the Occupational Clinic recently established at 49 Lafayette Street. For this work the compensation ranges from $300 to $600 per annum for not less than six hours a week, and from $900 to $1,140 per annum for not less than eighteen hours a week. The duties include the examination of applicants for licenses as food handlers. Clinic physicians for the diagnosis and treatment of patients applying at the Tuberculosis Clinics of the Department of Health are also desired. Further particulars may be obtained from the Municipal Civil Service Commission, Room 400, Municipal Building, New York.

The National Board of Medical Examiners held its first examination from October 16 to 21, in Washington, D. C. There were thirty-two applicants from seventeen States, representing twenty-four medical schools; of these, sixteen were accepted as having the necessary preliminary and medical qualifications, ten took the examination, and five passed. The following States now have the power, and are willing to recognize the license of the National Board: Idaho, Kentucky, Maryland, New Hampshire, North Carolina, North Dakota, and Vermont. Most of the others have expressed their willingness to accept the license as soon as the respective legislatures give them the power. The second examination will be held in Washington in June, 1917. Further information may be had by applying to Dr. J. S. Rodman, secretary, 2106 Walnut Street, Philadelphia, Pa.

Obituary Notes.—Dr. MATHEW J. MANGAN of Rutland, Vt., a graduate of the College of Medicine of the University of Vermont, Burlington, in 1905, died at his home on October 7.

The New Rochelle Hospital, New Rochelle, N. Y., receives $1,000 under the will of the late Mrs. Lydia W. Thorne, which provides also for the ultimate gift of the testator's country estate overlooking the Sound, to the city of New Rochelle, to be used as a public park.

Dr. JAMES P. CONNELL of Fond du Lac, Wis., a graduate of the Medical School of Northwestern University, Chicago, in 1887, and a member of the American Medical Association, the State Medical Society of Wisconsin and the Fond du Lac County Medical Society, died suddenly on October 22, at St. Agnes Hospital, after performing an operation, aged 54 years.

Dr. WILLIAM GUY FRIERSON of Shelbyville, Ky., a graduate of the Medical Department of the University of Nashville in 1897, died at his home on October 21, after a lingering illness, aged 41 years.

Dr. EUGENE ALEXANDER FREIS of Brooklyn, N. Y., a graduate of the College of Physicians and Surgeons, Columbia University, New York, in 1885, died at his home on November 6, aged 56 years.

Dr. NATHANIEL MCMASTER of New York, a graduate of Bellevue Hospital Medical College, New York, in 1868, a member of the Medical Society of the State of New York and the New York County Medical Society, and attending physician to the Demilt Dispensary, died at his home on November 8.

Dr. WILLIAM JACK MCMAHON of Courtland, Ala., a graduate of the Long Island College Hospital, Brooklyn, in 1860, and a member of the Medical Association of the State of Alabama and the Lawrence County Medical Society, died at his home recenty, aged 76 years. Dr. McMahon was a veteran of the Confederate Army.

Dr. WILLIAM C. IRBY of Laurens, S. C., a graduate of Jefferson Medical College of Philadelphia in 1870, died on October 26, aged 68 years.

Dr. WILLIAM ALTON BURR of Pasadena, Cal., a graduate of the Hahnemann Medical College and Hospital of Chicago in 1869, died recently, aged 76 years.

Dr. EDWARD WILLIAM SCHAUFFLER of Kansas City, Mo., a graduate of the College of Physicians and Surgeons, Columbia University, New York, in 1868, a veteran of the Civil War, and a member of the American Medical Association, the Missouri State Medical Association, and the Jackson County Medical Society, died at his home, from heart disease, on October 29, aged 77 years.

Dr. OWEN J. EVANS of Minneapolis, Minn., a graduate of Albany Medical College, N. Y., in 1862, died suddenly on October 17, from heart disease, aged 76 years.

Dr. EUGENE CLARENCE DUNN of Fresno, Cal., a graduate of New York University Medical College in 1881, and a member of the Medical Society of the State of California and the Fresno County Medical Society, died in a sanatorium in Fresno on October 14, from nephritis, aged 62 years.

Dr. FREDERICK C. WEAVER of Dayton, Ohio, a graduate of the Miami Medical College, Cincinnati, in 1894, and a member of the Ohio State Medical Association and the Montgomery County Medical Society, died at his home on October 14, aged 46 years.

Dr. Edward H. Grannis of Menomonie, Wis., a graduate of the Hahnemann Medical College and Hospital of Chicago, in 1875, and a member of the State Medical Society of Wisconsin and the Dunn County Medical Society, died at his home on October 14, from pernicious anemia, aged 62 years.

Dr. Frank C. Ferguson of Baltimore, Md., a graduate of the School of Medicine of the University of Maryland, Baltimore, in 1901, died at his home on October 11, from pleurisy, aged 37 years.

Dr. Gilman Corson Dolley, a graduate of the Medico-Chirurgical College of Philadelphia, in the class of 1907, died at Manila, P. I., on October 21, at the age of 37 years. He was resident physician at the Culion Hospital, Palawan.

Dr. Harry W. Weyant of Philadelphia, died of pneumonia on November 2, at the age of 47 years. He was graduated from the medical department of the University of Pennsylvania, in the class of 1895, and was for twenty-one years surgeon to the police department of Philadelphia.

Correspondence.

THE STORY OF A WINDOW TENT.

To the Editor of the Medical Record:

Sir:—My attention has been called to an advertisement in the *Journal of the American Medical Association* of the so-called Walsh Window Tent, in which it is stated that "four physicians invented it. The patents of Dr. W. E. Walsh, Dr. J. H. Williams, Dr. S. A. Knopf, Dr. W. B. McLaughlin are all combined and built into the Walsh Window Tent."

That I invented the window tent which bears my name, I do not deny. Those who saw my first tent, shown on February 27, 1905, at the meeting of the Medical Society of the County of New York, and the illustration of it in the *New York Medical Journal* of March 4, of the same year, and have also seen subsequent pictures of it in various publications (*New York Medical Journal*, April 22, 1911, Medical Record, October 31, 1914, Seventh edition of "Tuberculosis as a Disease of the Masses and How to Combat It") will even grant me that the device has been materially improved since it was first presented to the profession.

I protest, however, most energetically against the statement in this advertisement to the effect that I have taken out a patent on this device which was worked out particularly for the benefit of the consumptive poor who cannot have the luxury of an outdoor porch. I feel, however, that I must give the profession an explanation how this window tent came to be patented at all.

After having seen Dr. Bull's aerarium, which is an outdoor window tent, suitable for one or two-story country houses, but utterly impracticable for a New York tenement house, I was impressed with the possibility of devising an indoor window tent and eagerly began to work on the problem. At the time when I was experimenting with the device Dr. W. B. McLaughlin was my resident physician in the New York Health Department's Riverside Hospital-Sanatorium on North Brother Island. He claimed to possess mechanical ingenuity and I gave him my ideas of an indoor window tent, asking him to make a model and promising to give him an opportunity to read, together with myself, a paper on the subject of aerotherapy before the County Medical Society, when we would present this new device under our combined names. He made a model, which unfortunately was not satisfactory, and I then gave the idea of the device to the Kny-Scheerer Company and they made me another model suitable for presentation. In compliance with my promise, however, I asked the that-time president of the County Medical Society for a place on the program for the meeting of February 27, 1905, the paper to be entitled "The Open Air Treatment at Home for Tuberculous Patients, with the Description of a Window Tent and a Half Tent," to be read by S. A. Knopf, M.D., and W. B. McLaughlin, M.D. I wrote the paper and invited McLaughlin to be there to demonstrate the window tent. He promised to be present, but did not appear. I did not hear from him again until I learned to my amazement that he had taken out a patent for the window tent in his name. I interviewed patent lawyers to find out what I could do to contest the patenting of a device which I had invented for the purpose of giving air and light to the most unfortunate of the poor—the consumptives in the tenement houses of our large cities. I received a good deal of sympathy, but was told that such a suit was likely to cost several thousand dollars, and since Dr. McLaughlin had complied with all the legal requirements prior to taking out the patent, the outcome would be doubtful. I did not feel that I could afford to risk such a large sum, but in my popular writings on tuberculosis, including my International Prize Essay, I made it a point thereafter to describe the mechanism of the tent completely so that any one handy with tools could make one for himself.

From this little history of my window tent you will see that I have a very strong reason to protest against being designated as a patentee of a life-saving device intended for poor consumptives, to give them God's fresh air to which they should be entitled without extra pay to such of the medical gentlemen who claim to be inventors. I had intended that my indoor window tent should be free from all patent restrictions, just as the above mentioned half tent, sputum flask, and other devices which I have from time to time designed in my anti-tuberculosis work, are free to all who care to make them.

The saddest thing of all in this matter is that the manufacturers of my window tent, which, according to such authorities as Babcock of Chicago and Bonney of Denver, is ideal in every respect, claim that they can no longer manufacture the device without loss, owing to the large royalties they must pay to the owner of the patent, so that now the poor people who need it most will not be able to get the tent at a reasonable rate. I have written to the editor of the *Journal of the American Medical Association* asking him to refuse to publish the advertisement with my name, and I have no doubt that my request will be complied with. But among the readers of the Medical Record I believe I have a goodly number of friends who are not readers of the *Journal of the American Medical Association* and for that reason I ask you, Mr. Editor, to extend to this letter the hospitality of your columns.

S. A. Knopf, M.D.

Action of Salvarsan.—According to Citron injections of soluble mercurials cannot cause the disappearance of the Wassermann. Inunctions of mercury and injections of insoluble mercurials give much better results. Salvarsan has a clean superiority to mercury in any form, but has elements of danger. The author has seen it cause death in patients with visceral disease, especially in nephritis. The author gives both remedies in concert. —*Berliner klinische Wochenschrift.*

OUR LONDON LETTER.

(From Our Regular Correspondent.)

WOUNDED SOLDIERS ENTERTAINED — OUR DAY — ZEPPELIN RELICS—LUSITANIA MEDAL—OBITUARY.

LONDON, October 23, 1916.

FIVE thousand wounded colonial soldiers were entertained at a fête in Windsor Great Park last Saturday afternoon. Australians, New Zealanders, South Africans and Canadians were all present, and all had had their part in the fighting, and many had wonderful stories to tell. They were gathered from about thirty hospitals in and around London. The king showed his interest by granting the use of the park for the occasion, and Princess Christian, the Duchess of Albany, Princess Alexander of Teck and her little daughter, Princess May, paid a visit during the afternoon. The gathering originated with Mrs. R. D. Fiske, who has previously entertained wounded soldiers on a large scale, and was on this occasion backed by the officials of the Australian Commonwealth, the gathering being arranged to commemorate the departure of the first Australian contingent to the front, just two years ago. The weather was October's finest, and this contributed largely to the success of the entertainment, for it seemed rather risky to hold an outdoor gathering in the middle of October. It was no slight undertaking to provide for so many men. There were 1,250 pounds of meat, 4 tons of flour, 6 hundredweight of sugar, 1,000 pounds each of currant and plain cake, 12 barrels of grapes, 15 boxes of apples, 150 pounds of tea, £25 worth of butter, and 20,000 cigarettes. The cavalry exercise ground was specially laid out by the crown authorities for the occasion, water was laid on, and about a dozen field ovens installed for the purpose of boiling it. Two huge marquees were erected, each capable of accommodating a thousand men, tea being served in batches. The men came by train, motor cars, and all sorts of vehicles, some even on steam launches, by river, a taxicab association brought 250 bad cases from the London hospitals, and there were many private cars.

The celebration of "Our Day" on Thursday was a great success, and the Red Cross Society and the Order of St. John will benefit accordingly. The weather was all one could hope for in a London October, and almost every one you met in the street wore the flag which betokened some gift to the cause. Four millions of these flags were offered for sale in London alone, and nearly all were sold. For the Empire 35 millions were provided, and it is said not many were left in the hands of the ladies who sold. The flags were of paper, silk, and other materials, and of various handsome designs. There were also real zeppelin relics offered for sale, which found ready purchasers. Brooches, bangles, and other ornaments, woven with wire from the wreck of the Cuffley zeppelin, disappeared as soon as they were offered, at prices from one shilling to ten, in some cases twenty. Well-known ladies in large numbers presided over stalls in large hotels and public places. Society was fully represented, both in the audience and among the indefatigable sellers of programs.

A medal in commemoration of the Lusitania disaster fetched £300. The king gave to the fund £5,000 the queen £1,000, the Prince of Wales £1,000, Queen Alexandra £500, the Australian Branch £31,000; 30 contributors between them subscribed £76,184. It was felt that no amount could exceed the needs of the fund, which in the ordinary course of a week expends £40,000 on the wounded. Last year the amount raised on "Our Day" exceeded £1,000,000, and this year a larger sum is hoped for.

An exhibition of zeppelin relics has been held in the city for some weeks. It attracted some 20,000 visitors daily, and a collecting box realized over £1,000, principally in coppers, for the Red Cross Society and the Lord Kitchener memorial fund. Later a private view was held in aid of the Countess of Denbigh's war hospital.

The death has occurred of Mr. R. W. Doyne, the eminent ophthalmologist of Oxford, of which he was Hon. M. A. 1902. He was surgeon to the Oxford Eye Hospital for more than 25 years and was consultant to the Radcliffe Infirmary, and first reader in ophthalmology to the university. The congress on this specialty was originated by him, and he was for many years its leading spirit. He contributed valuable papers to the journals and wrote a book on the "More Common Diseases of the Eye," the value and misuse of spectacles in the treatment of headache, migraine and other functional troubles of the eyes, and undescribed forms of iritis, family choroiditis and conjunctivitis were illustrated by him in ophthalmic transactions.

Dr. G. A. Heberden of Victoria, S. A., great grandson of the famous Wm. Heberden, has died at the age of 55. He took the double qualification in 1888. The next year he went to South Africa, and practised there throughout his life. As M. O. H. at the siege of Kimberley, he was awarded the D. S. O.

Dr. W. Symington, J. P. for Brampton, Cumberland, where he practised for 28 years, died there on the 3d inst., aged 51. He was a surgeon-major of the Fourth Border Regiment (T. F.). He was attacked by blood poisoning about four months ago, which has proved fatal.

Dr. W. A. Haslam, R. M. O. Hull Fever Hospital and Sanatorium, died September 1 of fever contracted in his occupation. He was a Guy's man, aged 51, took the double qualification in 1892, was M. O. H. of Prescot (Lanes) Infirmary, 1898, and in 1911 entered the service of the Hull Corporation.

2. **A Study of the Symptoms and Treatment of Congenital Transduodenal Bands.**—John Homans, having met with a number of instances of these bands or adhesions, deemed it worth while to make a study of all such cases occurring over a period of several years at the Peter Bent Brigham Hospital. The investigation was undertaken to throw light upon the question whether transduodenal bands of congenital origin give rise to such symptoms as to cause them to be considered a pathological entity, having a definite course, symptomatology, and treatment. Eleven cases were studied in which definite bands passing from the gall bladder and liver across the duodenum were found, and in which gastric or duodenal ulcers or gall-bladder dis-

ease had been held to be absent. There were six males and five females, the average age of both being forty-four years, the youngest nineteen and the eldest sixty-seven. The average duration of symptoms was eight to nine years. The general character of the patient's complaint tended to resemble that of ulcer or gall-bladder disease, but gave the impression of a reflex symptom-complex. In respect to intermittency, the symptoms resembled gallstones or chronic appendicitis rather than ulcer; in respect to food relief, those of gallstones and chronic appendicitis rather than gastric or duodenal ulcer; but when food was present it simulated duodenal or pyloric ulcer in type. In respect to vomiting, the disease was rather like gastric ulcer or gallstones; while in respect to bleeding, band cases presented negative findings. In Roentgen-ray studies these cases tended strongly to imitate duodenal ulcer. Homans, at the same time, made a comparative study of six cases of duodenal ulcers and six of gastric ulcers. In the preoperative diagnosis of these cases there was no mistake, while in the diagnosis of the eleven band cases much inaccuracy was displayed. In but three of the cases was the existence of bands suggested, while ulcers of all types, gallstones, and cancer were considered as the cause of the condition. The Roentgen examinations in gastric and duodenal motility and in the position and outline of the stomach and duodenum showed abnormalities in all instances of well-developed transduodenal bands in eight out of the eleven cases. Three cases were not so studied. Of the eleven cases operated on, one that of an old lady who died one month after leaving the hospital, probably of cardiac condition, ten have been followed for periods of two and a half years in the first case to four months in the most recent. Three patients died shortly after operation of intercurrent diseases. Of the eight living, all are well or express themselves as satisfied with the results of the operation. Homan treated these cases by making a division of the transduodenal bands, and in two instances opened the duodenum and performed a Finney pyloroplasty. From the study and operation upon these cases he draws the following conclusions: (1) Congenital transduodenal bands may be responsible for symptoms "reflex" in type which have, in spite of considerable divergence, a definite family resemblance; (2) accompanying these symptoms the Roentgen findings very generally indicate duodenal spasm or dilatation of the first, or first and second, portion of the duodenum; (3) division of the bands and appropriate treatment of raw surfaces is satisfactorily curative, but plastic operations to widen the opening into the duodenum probably give the best results; (4) congenital transduodenal bands, judging from the frequency with which they are reported at autopsy, are not necessarily pathological, but may be responsible for digestive disturbances having a recognizable symptomatology, a prolonged course, and appropriate operative treatment.

6. **Control of Scarlet Fever.**—D. M. Lewis, epidemiologist, Board of Health, New Haven, Conn., states that, from lack of epidemiological observations on sporadic or endemic cases, the control of this disease is as yet limited to the search for missed cases and the supervision of reported ones. He shows that it is possible to demonstrate the carriers of this disease, who, as responsible for the missed as well as the reported cases, are consequently the basis for the control of scarlet fever. He cites eight cases, ranging from seven to twenty years of age, who were carriers of scarlet fever. One case, a boy aged five, was reported November 2, 1914. Released at expiration of six weeks, with discharging ears and purulent nasal discharge. During following two months there were four neighborhood cases in children of the same age. Almost a year later Lewis found the same boy being admitted to a day nursery with his ear filled with cotton, a purulent nasal discharge, a marked streptococcus sore throat, a strawberry tongue, and a temperature of 102°. Without ensuing rash or desquamation, it was only after six weeks' treatment that the nasal discharge was cured and the tongue faded. Carriers may be divided into two groups: those individuals having ear or gland discharges at the end of convalescence, and those who have had the disease previously. The one essential is that both groups shall show some grade of buccal-pharyngeal inflammation as shall be characteristic of primary scarlet fever. With the subsidence of this factor in the first group and its absence in the second group, Lewis does not find individuals infective. Lewis not only carries out strict quarantine measures, but any carrier in the family, house, or neighborhood was isolated, though given rear-yard freedom. Inspection of adults was insisted on only when there was a history of previous sore throats or the adult was a raw-food handler. Postal-card notification of all school absentees, as well as those who are in school and have nasal or ear discharge, is the basis for finding carriers. During the last four months of 1915, with some thirty-nine reported cases, he has a record of twenty-one carriers found, as well as three missed cases; for the first five months of 1916, with some ninety cases of the disease, a record of ten carriers and two missed cases. He says in conclusion that he has abolished recurrent cases, made infrequent secondary cases, and lessened reported cases by demonstration of carriers of convalescence and carriers previously having had the disease and by isolating these carriers. Results of so-called grading of quarantine does not depend on the quarantine, but upon the fact of the presence of the carrier being within or without the family circle. Full liberty may be safely given to all contacts who are free from the signs of the disease at the time of isolation of the one sick and the carrier. Control of scarlet fever will be found to lie in the supervision of those who have previously had the disease, at and during those periods when with intercurrent infections they again show the buccal-pharyngeal signs of scarlet fever. Secondarily, missed cases and the convalescent reported cases are of equal importance.

1. **The Blood and Its Vessels in Epilepsy, and Their Treatment.**—Thomas E. Satterthwaite states that though it has long been known that circulatory derangements are produced by epilepsy, it is only during recent years that it has been found, conversely, to produce epileptic attacks. In the three principal varieties of this disease circulatory disturbances are among the dominating features. He does not include Jacksonian epilepsy, because circulatory anomalies are not constant features of the neurosis. He refers to many authorities on this disease with reference to the circulatory conditions found, and quotes Gower as advo-

cating many years ago the use of nitroglycerin. Echeverra of New York about half a century ago stated that cardiac diseases might originate epileptiform convulsions from embolism of the cerebral arteries. Sachs has recently reported one case in which focal epilepsy was produced by enlarged veins in the pia mater and another by similar conditions in the dura mater. Another case is referred to in which the epileptic attacks disappeared after the vascular growth at the base of the brain had been removed by operation. After referring to the general hygienic and therapeutic management of epilepsy, Satterthwaite is led to the following conclusions: (1) Abnormalities of cardiovascular phenomena occur in the vast majority of epileptic seizures. (2) The grosser forms of cardiac disease rarely occur in epilepsy. In fact, they are present in so small a proportion as to indicate that they are accidental rather than determining factors of it. (3) That a cerebral disease or abnormality may produce epilepsy is well established. The evidence shows that removal of enlarged veins or nevoid growths adjacent to the base of the skull has been followed by cessation of the seizure. (4) There is therefore a reciprocal relation between circulatory disorders and epilepsy to this extent; that epilepsy causes circulatory disturbances and that abnormalities of blood or vessels cause epilepsy. This reciprocal relation he believes to have been hitherto overlooked. (5) In most forms of epilepsy there is cerebral anemia, and this is relieved effectively by various heart stimulants, the high-frequency current, and radiant electric light. The importance of the use of cardiac stimulants in epilepsy has not been properly appreciated by the profession.

2. **Strychnine as a Tonic.**—William F. Milroy puts up a plea for strychnine, for he believes that the profession as a whole only half appreciates this old time remedy. Doctors are afraid of it. Few realize what it can accomplish in maximum doses; it is in this phase of the subject that he is especially interested. He uses it chiefly in cases of pulmonary tuberculosis, where it can be tolerated and be made to produce beneficial results over a period of years; while in nervous disorders representing conditions of depression good results are to be obtained. Also in pneumonia, when edema is forming in the dependent portion of the unaffected lung, prompt relief can be given in a few hours by the injection of one-sixth grain of strychnine. Its action is primarily upon the nervous system, including the sympathetic system, producing a stimulation of the physiological activity of practically the whole body. Admitting that cardiac muscular power and blood pressure are not influenced by strychnine, nevertheless the heart action is influenced favorably in certain conditions, such as irregular, intermittent heart. Cellular nutrition is not a process of passive absorption, but is an active, vital process under the direct control of the nervous system. Therefore the profound stimulation of the nervous system by full doses of strychnine directly promotes a new and vigorous cell activity of the whole body, thus tending to restore the lowered opsonic index. Milroy usually administers the drug by mouth, four doses daily, beginning with one-thirtieth grain and adding one-thirtieth to the daily allowance at the end of each five-day period until eight-thirtieths are given daily, then reducing the increase to one-sixtieth until the limit is reached. The maximum dose is indicated by the occurrence of muscular rigidity. Though the drug may not be wholly eliminated from the body under eight days, it is practically gone at the end of twelve hours, and therefore the doses must not be too infrequent. No tendency to habit formation can be induced, and a perfectly safe margin exists between the first appearance of muscular spasm and a really poisonous dose.

4. **Epilepsy.**—T. E. McMurray announces that in his limited experience with epilepsy the following facts impressed him strongly: Digestive disturbances as manifested by foul breath, coated tongue, constipation, and intestinal gases; the enormous appetite, especially for bread and sweets. He reports three cases out of eleven treated according to his treatment in which improvement has been marked as indicated by an absence over a continued period of time of the convulsions and improved general health. The diet followed was that outlined for diabetes, otherwise starch and sugar free. He recommends to these patients Hill's book on diabetes, thereby giving suggestions for a more liberal diet. McMurray also included pancreatin and sodium bicarbonate at meals, a dose of epsom salts every fourth day, and mineral oil daily if needed to keep the bowels active. In only two cases was it necessary to give bromides, and then only for a short time. In two of his cases convulsions returned after excesses at the table and disappeared after the diet was restricted again. The cases all showed gastric hyperacidity, acidosis, but no glucose in the urine. A blood test for sugar was not made.

1. **The Health Education of the General Public.**—W. C. Rucker states that in order to accomplish anything in a public health way it is necessary that the sanitary authorities have the financial and moral support of the citizenship. As assistant surgeon-general, United States Public Health Service, he speaks with authority when he says that if the general public is not informed as to the need for personal and public hygiene and sanitation, it is extremely difficult to secure public health. More and more time is being devoted in efforts to bring these facts before the public; but the work has only just begun, and he considers that there is at least thirty years of hard work ahead before maximum results will be achieved. If publicity be of the right sort and carried on with a full understanding of the mass psychology, it will achieve good results in the end. While the spoken word, the mass meeting, has a certain place in public health education, it must not be forgotten that only those who are interested in the problem come to the lecture. Too much dependence has been placed in the spoken word. What the American people want is more demonstration and less talk in public health work. Demonstration takes many forms, including stereopticon slides and motion picture films. In reference to the first method, the pictures should be good enough to tell their own story without the aid of the lecture, and the same may be said of the lecture. Moving picture films have not been absolutely successful; the sanitary scenario must be sugar-coated

in order to live up to the traditions of the motion picture stage. Printer's ink is the greatest medium of public health education. Intelligent, well-written newspaper articles, prepared after due consideration of the psychology of the average newspaper reader, are of the greatest benefit. The greatest sanitary hope of the future lies in the health education of the child. This must begin with the kindergarten and extend through to college days. The general public does not know how much good can be done them. We must create in them a demand for public and personal hygiene. It would be well to study the methods which have been used in popularizing manufactured articles and to change the plan just enough so that it may better fit this important work which lies ahead of the medical profession. He considers that the American Medical Association has already accomplished much in this field, but there is much more to be done.

4. **The Use of Malt Soup Extract in Infant Feeding.**—B. Raymond Hoobler. (See MEDICAL RECORD, June 24, 1916, page 1163.)

5. **Rest of the Individual Lung by Posture.**—Gerald B. Webb, Alexius M. Forster, and F. M. Houck state that respiration in a normal person takes place upward of 30,000 times in twenty-four hours. When a tuberculous patient rests on one side at night, the dependent lung is restrained in motion; but the upper lung opens and closes about 12,000 times in ten hours of sleep. They have noticed a marked tendency for the consumptive to lie on the side of the better lung at night, and it often happens that the very lung which needs the most rest is getting the most work. For various reasons it would seem that the majority of normal persons sleep on their right sides. While Walsh pointed out that in pulmonary tuberculosis the disease would seem to begin in most patients at the right apex, the writers have noted that they have had more patients needing pneumothorax with extensive left-sided than with extensive right-sided tuberculosis. From history one would suppose that the disease would be more widespread in the more exercised lung; but the fact that the majority of persons sleep on their right sides and that the majority of advanced tuberculous lesions are apt to be found in the left lung may not prove to be entirely coincidental. The experiences noted from successful artificial pneumothorax show the great value of rest of the individual lung. During the past year they have applied this principle of rest in a large number of cases, and in addition have placed a small firm pillow to restrain the motion of the diseased lung to a greater degree. Some patients so treated have been able to remain lying on the side of the diseased lung over twenty hours a day for months at a time with little effort. This must be accomplished gradually. The results were encouraging, and the writers feel that they have observed in certain cases a cessation of fever, a diminution of expectoration, and lessened liability to relapses. In a tuberculous patient a moderate degree of hyperemia is thus produced by this rest on the affected side. Rest on the right side must be done occasionally in order to afford drainage when needed. It would seem wise, the authors think, to observe all patients who suffer from either nocturnal or early morning hemorrhages, with a view to ascertain, if possible, the side on which they have slept at night.

8. **Bacteriological Findings in Cerebrospinal Fluid in Poliomyelitis.**—John W. Nuzum states that it is the opinion of those familiar with the bacteriology of poliomyelitis that the cerebrospinal fluid, whether obtained by lumbar puncture during life or at necropsy, is sterile. Recently he reported the isolation of a gram-positive micrococcus from the cerebrospinal fluid during life in eight out of nine cases of acute poliomyelitis, and a little later this same peculiar gram-positive microorganism has now been isolated from the spinal fluid in forty-five out of fifty cases studied. It presents the same cultural and morphologic characteristics as does the micrococcus isolated from the brains and spinal cords in fatal human cases at necropsy. Control cultures were made with the cerebrospinal fluid obtained by lumbar puncture from normal individuals and from patients afflicted with diseases presenting more or less clinical symptoms resembling infantile paralysis, such as brain tumors, tabes, tic, etc. In no case was the peculiar microorganism characteristic of poliomyelitis obtained. The cultures were made as follows: From 1 to 2 c.c. of the spinal fluid was regularly inoculated into a series of four tall tubes containing ascites dextrose broth, ascites broth, human ascitic fluid, and ascites broth to which a sterile piece of rabbit's kidney was added. The tubes were inoculated at 35° C. At the end of twenty-four to thirty-six hours a diffuse turbidity commonly appeared in all four tubes of the positive cultures. Control tubes remained clear. Smears made at this time usually revealed a minute organism, gram-positive and arranged in pairs, clumps, and short chains. Many were so minute as to be just visible under the oil immersion lens. They corresponded in every morphologic detail to the minute globoid bodies described by Flexner and Noguchi. A further description of the tubes containing the cultures at the end of forty-eight to seventy-two hours was given, and the smears made then show a larger form of the same organism. Any routine clinical test would be of inestimable value in these cases of poliomyelitis, especially the atypical cases. It was hoped that complement fixation tests might prove a valuable aid in diagnosis. Bacterial antigens were prepared from the cultures of the brains and spinal cords at necropsy. With suitable controls hemolysis resulted in a large number of cases tested. A number of cases are reported by the author in order to illustrate the value of the isolation of the organism as a routine measure. In the cases reported the disease resembled poliomyelitis, but examination of the fluid showed none of these organisms. At necropsy the true cause of each condition was found, and none was a case of poliomyelitis.

10. **The Treatment by Radium of Carcinoma of the Prostate and Bladder.**—Benjamin S. Barringer gives the results of his experience with this form of treatment, and states that problems presented by bladder and prostate carcinomas are so entirely different that they must be considered separately. He gives the technique of using radium in both conditions and reports of cases, and offers the following summary: By means of radium we have caused the rapid and complete disappearance of two bladder carcinomas out of nine treated. These cases were carcinomatous by cystoscopic appearance and microscopic examination. Time only will tell whether these patients are cured. In one case of prostatic carcinoma, treated for six months, the carcinoma and the symptoms have markedly retrogressed. In another case, treated three months (possibly borderland), the symptoms have improved. Of three other patients treated, one is dead, one has only recently been treated, and one is doing a full day's work but could not be reached for examination.

2. Some Observations on Dysentery.—William Magner divides this disease into two more or less distinct stages, due to the pathological aspect of the large intestine. The early stage of this condition is characteristically apyrexial, but the later stage is pyrexial due to the bacterial invasion of the intestinal walls. As a result of his work on a large number of cases of dysentery he draws the following conclusions: (1) Both in amebic and bacillary dysentery secondary invasion of the ulcerated intestinal wall by organisms from the intestinal lumen is an important factor aggravating both the local and general condition. The pyrexia so frequently observed in the later stages of amebic dysentery is a result of this secondary invasion, and, though usually toxic in origin, may be due to bacterial invasion of the blood stream. A similar septicemia may occur in the bacillary type of the disease. (2) Amebic dysentery may be latent, the ulcers being confined to the cecum and producing no symptoms. Apart from the danger of the disease becoming active, such cases may act as foci for the spread of the disease. (3) Every case of amebic dysentery should be treated by the administration of at least 10 grains of emetine. Incomplete treatment may result in the patient becoming a cyst carrier and a danger to the community. (4) The prevention of amebic dysentery depends upon the elimination of cyst carriers, rapid and complete disposal of fecal matter, and protection of food from dust and flies. (5) In bacillary dysentery the earliest pathological change in the intestinal wall is dilation of the vessels and a marked hemorrhagic exudation into the submucous coat. Leucocytic accumulation is a later phenomenon resulting in necrosis of tissues. (6) Mannite-fermenting dysentery bacilli can exist in the intestine in an avirulent form. The presence of such an organism in the stools loses much of its significance in the absence of a positive Widal reaction. (7) The agglutination reaction in dysentery is a valuable means of differentiating the bacillary type of the disease. In Shiga infections specific agglutinins are invariably present after the first week of the disease. Distinct agglutination with a serum dilution of 1 in 100 is diagnostic. (8) Judging from serological tests, it would appear that certain organisms, normally saprophytic, may in both types of dysentery stimulate the production of specific agglutinins as the result of invasion of the ulcerated intestinal wall. (9) The toxins of Shiga's bacillus are highly pathogenic to rabbits. Subcutaneous injection with either living or killed cultures results in the development of paralytic symptoms and death. The characteristic lesions of the human disease cannot be readily reproduced.

3. A Series of Military Cases Treated by Hypnotic Suggestion.—J. Bennett Tombleson reports the result of sixty cases which he has treated by this method of therapeutics. He considers the most successful results were obtained in cases of shock psychasthenia of all kinds, while cases of hyperthyroidism and neurasthenia also showed good results. So far as he has been able to trace them, the cure has been permanent in these cases, and he suggests that if the same standard of criticism be applied to these cases and to similar cases treated in other ways the utility of hypnotic suggestion would be obvious to any fair-minded critic. Among the cases treated were those of neurasthenia due to shock but with a history of condition some time before the war; psychasthenia, due to injuries; trench shins, due to exposure in Balkans; epilepsy, in which fit had occurred every two months but oftener since enlistment; hyperthyroidism, and chronic rheumatism.

5. The Surgical Uses of Ozone.—George Stoker considers this method of treatment of wounds satisfactory from every standpoint. He gives the results of the first twenty-one cases treated at the Queen Alexandria Military Hospital, which cases were for the most part those of cavities and sinuses in the femur and tibia. The apparatus used is known as an Andriolis ozoniser, and the treatment consists in the application of ozone to the affected parts. The properties of ozone, which have a wonderfully healing effect, are, as far as is known at present, three: (1) It is a strong stimulant, and determines an increased flow of blood to the affected part. (2) It is a germicide which destroys all hostile microorganic growth. (3) As the French chemist Hennocque has shown, it has great powers in the formation of oxyhemoglobin. The ozone is applied on the wounded surface or to the cavities and sinuses for a maximum time of fifteen minutes, or until the surface becomes glazed. Ozone has the particular power of disclosing dead bone, foreign bodies, septic deposits, etc. This it does by destroying the granulations and microorganic growths (presumably unhealthy) that are found in close contact with septic deposits, foreign bodies, or dead bone. Cleansing and Dressing: Wounds and sinuses, etc., are washed twice daily with boiled water and a dressing of dry gauze is applied. It must be observed that at first ozone causes an increase of the discharge of pus; later on the pus is replaced by clear serum, which at a still later stage becomes colored reddish or pinkish. In open wounds it is necessary to strip off the parchment-like film surrounding the edges, which is composed of oxidized serum. This is easily effected by applying a hot compress for fifteen or twenty minutes, after which the film can be easily peeled off with a dissecting forceps.

7. Left Fallopian Tube Found in Left Femoral Hernia.—E. G. Renny presents a report of a case of this condition, and states that he has found no record of a similar case. The patient, aged forty-two, married, mother of three children, noticed a lump in the left groin for eighteen months. During the last five weeks it had become painful, and, thinking it was a rupture, she bought a truss and wore it. The truss made the lump very inflamed and painful. She then consulted Dr. Renny, who found a painful swelling in the groin which, on account of the inflammation present, made the diagnosis uncertain. It was dull to percussion, irreducible, with no impulse on coughing and no strangulation symptoms. The finger could be passed up the inguinal canal for a short distance. Later, after rest and a subsiding of the inflammation, an incision was made over tumor. It proved to be a femoral hernia with somewhat thickened sac, containing a considerable quantity of green fluid, under tension. Occupying the crural canal was a red, soft substance which, when traction was made on it, proved to be the left Fallopian tube, with its fimbriated extremity presenting. This was returned to the abdomen without much difficulty.

2. Practical Hints on Functional Disorders.—M. Culpin says that eighteen months' service has convinced him that much harm is done by failure to recognize psychical disabilities which, though sometimes so extraordinary as to deceive the most wary, should generally be diagnosed by anyone who is awake to their possibilities. Tests of sensation should be applied where there are not enough signs fully to account for all disability present. To differentiate between conscious and unconscious simulation is necessary but often difficult; sometimes the hysteric is a good fellow who deserves sympathy more than is consistent with cure; sometimes he resists all treatment and may say that he has no wish to be well. Among the types of cases tested and treated was one of talipes varus with a decided obsession; tilted pelvis with scoliosis and apparent shortening of a leg, which condition can be produced at will; paraplegia after shell-shock, which may, however, be genuine and needs careful diagnosis; frostbite, rheumatism, and abdominal psychoses. Culpin urges that a careful watch be kept for such cases when they begin. There is no mystery in the diagnosis; ordinary methods of examination, supplemented by sensory tests, detect the majority of them. In every injury the extent of possible movements should be early ascertained, and if no contradictions are present these movements should be strongly encouraged. A man whose functional disorder is diagnosed as organic will probably be a cripple for the rest of his life; the longer he remains under the shadow of a wrong diagnosis the harder will be the cure when his true condition is recognized.

3. Preliminary Note on the Intravenous Injection of Gynocardate of Soda in Leprosy.—Sir Leonard Rogers, who has had a long experience with this treatment as well as with the subcutaneous method, and published the results of the same in a recent paper, gives a further statement. He gives a detailed description of the method of preparation of sodium gynocardate and the technique of intravenous injections. He says that the two great advantages of the intravenous over the subcutaneous method are its painlessness and greater efficiency. Several months are required to produce an improvement by the subcutaneous method, while by the intravenous method the improvement is decidedly rapid. This is a big factor, since many of the patients refused to return until any material result could be expected from the subcutaneous method, while from the shorter method results are practically sure. The most striking result is the occurrence of definite local reactions in the diseased tissues, sometimes accompanied by fever. A most decided reaction was in the greatly thickened ears of a tubercular case, in whom fever occurred for three days, with redness and swelling of the helix, accompanied by some serous discharge containing broken-down leprosy bacilli. After the subsidence of the reaction at the end of ten days the diseased tissues were softer and less indurated than before, while nodules on the face, not showing the local reaction, were also diminished in size. In two anesthetic cases, with greatly thickened ulnar nerves, tenderness and slight swelling appeared in the affected portions after intravenous injections, which has been followed by some return of sensations in previous anesthetic areas of the hand. It is thus clear that intravenous injections of the drug have produced selective local reactions in the diseased tissues with the greatest amount of infiltration of the tissues with leprosy bacilli. While the results obtained have been decidedly beneficial and no ill effects have been found to follow these reactions, yet the possibility of dissemination of the bacilli in the body must not be lost sight of. Rogers concludes from the 200 intravenous injections of gynocardate he has given that he will substitute that method entirely for the subcutaneous method.

4. Treatment of Certain Diseases of Protozoal Origin by Tartar Emetic.—Aldo Castellani, acknowledging the work of other men in this direction, states that he has experimented with it in the tropics in the treatment of yaws, kala-azar, Oriental sore, and relapsing fever. The mode of administration varies, depending on the accessibility of the patient. Tartar emetic, though efficacious in yaws, is far from being speedily curative, and gives better results when combined with other drugs, of which potassium iodide is most beneficial; mercury has practically no action. He uses what is known as the Castellani mixture, which contains tartar emetic, sodium salicylate, potassium iodide, sodium bicarbonate, and water. The active drugs in the mixture are the tartar emetic and potassium iodide, while the sodium salicylate, though not having any specific effect on the malady, seems to hasten the disappearance of the thick, yellow crusts capping the framboeting nodules. The sodium bicarbonate decreases the emetic effect and prevents to a certain extent the symptoms of iodism. Tartar emetic was first used by Castellani for the cure of kala-azar. He treated children between two and four years for this disease. One case died, due to the fact of being in a dying condition when presented for treatment. The others recovered, treatment having been given to some intravenously, to some intramuscularly, and others by oral administration. In one both intramuscular injections and oral administration of the drug was used. In the intravenous injections the usual 1 per cent. tartar emetic solution in sterilized normal saline answers well; tartar emetic in 2 per cent. carbolic acid solution is also used, especially in relapsing fever. Half to 2 c.c. is diluted at the time of injection with sufficient sterile saline to bring it to 5 c.c. and the whole injected into a vein, taking the usual precautions. For intramuscular injection tartar emetic gr. viii, carbolic acid ♏ x, glycerin ʒiij, and distilled water to ʒj. Half to 1 c.c. is given every other day intramuscularly. The oral administration is given in conjunction with the two other methods, and tartar emetic gr. v, bicarbonate of soda gr. xxx, glycerine ʒj, chloroform water ʒj, and water to ʒiij can be given one to two teaspoonfuls in water three times a day. This dose can be doubled for adults. He concludes that tartar emetic is of great efficiency in various protozoal diseases such as already mentioned, and seems to have a beneficial effect also in relapsing fever.

7. Digested and Diluted Serum as a Substitute for Broth for Bacteriological Purposes.—A. Distaso claims that this substitution allows for a more luxuriant growth of the *B. coli* group, the streptococci, the staphylococci, *B. subtilis*, *B. proteus*, and *fluorescens*, and that, compared to it, the growth on normal broth seems scanty. The medium is prepared as follows: (a) One volume of sheep or ox serum is mixed with one volume of tap water, and boiled till it becomes milky. (b) A pancreas of a pig is minced and extracted with 400 c.c. of distilled water in the presence of chloroform for twenty-four hours. (The first experiments were performed with 1 per cent. trypsin, but, for the sake of economy, afterward pancreatic extract was used, which is equally suitable for the purpose.) (c) A piece of the upper part of the small intestine is extracted in the same way in order to activate the pancreatic extract. (d) To one liter of (a) is added 100 c.c. of (b) and 10 c.c. of (c), and digested at 60° C. for the night. Next morn-

ing the flask contains an amber-colored liquid with fine flocculi floating in it. Filtered through Chardin paper, the amber-colored liquid passes through and the flocculi remain in the filter. The liquid is collected and sterilized at 120 C. for fifteen minutes, then tubed and resterilized.

Medicine in the University of Warsaw in the Past.—Brudzinski gives a survey of medical teaching in the university during the old Polish cycle. Nawrocki, the physiologist—with particular reference to the nervous system—was active in the university from 1867 to 1874, at which period the stifling advent of Russianization interrupted his career. His was not a strong character. There remain for consideration Szczucki and Luczkiewicz. The former lived during 1786-1832. He joined the faculty of Warsaw University in 1818 as professor of medicine and pathology, and in 1825 began to deliver lectures on the history of medicine. He was a fanatical advocate of Latin for medical instruction, which interfered with his usefulness. The opposition to the mother tongue on the part of a Polish teacher shows that the Russians did not exactly originate this proscription. Luczkiewicz lived 1826-91. Not until 1862 did he join the medical faculty, and in 1864 began to teach pathology and therapy. His literary activity was marked, and he founded no less than three prominent journals, edited a cyclopedia of medical science to which he was also a contributor, wrote a text-book on diseases of the nervous system, and was also a prolific translator. No activities are mentioned after 1876, and his status in the Russianized university is not given. The credit awarded to Szczucki and Luczkiewicz is chiefly because of their broad activities in attempts to fix the status of medicine as a science and art, to write its history, to look ahead, to preserve the national traditions, and especially to determine the preliminary instruction best adapted to a medical career (propedeutics).

Uric Acid Reaction in the Saliva.—Von Noorden (and Fischer) reports briefly on this subject, and refers to the elaboration of Folin's calorimetric method for the general determination of uric acid. This rests on measurements of the blue color which arises when phosphotungstic acid acts upon uric acid in the presence of soda solution. This method has done well in blood determinations of uric acid, and doubtless our knowledge of blood urea has been considerably increased by Folin's method as contrasted with the older procedures for which large quantities of blood were required. As far back as 1889 Medicus was speculating as to the practicability of a test based on the blue color liberated in phosphotungstic acid precipitates as a means of determining the amount of uric acid and other related substances, but so far as known he abandoned this lead. The author and van Ackeren, however, used this principle in determining the presence of uric acid in the perspiration. They found a marked positive result in gouty and nephritic cases. The author then proceeded alone in tests of gastric juice and saliva, the former being invariably positive. With saliva there was a positive result in chronic nephritis and gout and a faint reaction in normal men. The announcement of Folin's special method at once caused the author, in cooperation with Miss Fischer, to take up again the old line of research. The results are thus far as follows: After the mouth has been cleansed, saliva is induced to flow by chewing movements and exercise of the tongue. Most of the fluid comes from the submaxillary glands. When to the saliva is added phosphotungstic acid and soda solution a blue color almost always appears. If the reagent and saliva are present in equal proportions this color varies between light sky-blue and deep blue. The saliva should be diluted with water and acetic acid added cautiously to get rid of the mucus. Albumin is now precipitated by boiling and the filtrate tested again for albumin with negative results. The phosphotungstic acid now gives a positive result. Each ingredient of saliva when individually tested gives a negative result, showing that some alien substance must be involved. When Folin's technique for blood urea was applied traces of uric acid were found—up to 10 mg. to 100 c.c. saliva. The highest values were, as already stated, associated with gout and nephritis. In very young subjects 1 or 2 mg. appear to be normal. The authors have as yet a number of problems to work out. It must be learned whether uric acid can be ranked as a normal constituent of the saliva.

Investigations into Typhus Fever.—H. da Rocha-Lima in his studies of this subject ignores completely the claims of Proescher and denies that the Plotz organism is the cause of the disease. He is concerned chiefly with the finds in the body louse, rather than with the various organisms recoverable from the infected blood. He goes back to 1910, in which year Ricketts and Wilder announced the discovery of certain polar-staining organisms in infected lice. Since that period a number of observers, including the author, have independently discovered this organism in the louse, and it has even been claimed that it has been seen in the normal louse. The author, at first with Prowazek and later by himself, found, as a result of hundreds of experiments, that certain corpuscles could be recovered only from lice which had sucked blood from typhus patients. These he named the *Rickettsia Prowazeki*. In the absence of cultures a suspension of the infected portions of the louse injected into guineapigs not only gave the same picture as when typhus blood is injected, but also conferred immunity. Suspensions of normal lice were used as controls, and proved negative. The Rickettsia cannot be made to grow on Plotz's medium, nor as yet on any other. Its nature cannot be determined, and morphologically similar formations may be seen in smears, so that the sole identification at present is the inoculation test. Since the preceding was written the author has pursued his researches and has found that when lice are allowed to feed on a convalescent typhus patient they never become infected. In other words, there is no such a person as a healthy typhus carrier. The second generation of lice which have been infected very seldom have the disease (one positive result in thirteen cases). Immediately after, and even at times during, defervescence the blood is so nearly sterile that lice are but seldom infected. At the other extreme the blood may not infect the louse until the fourth day of the disease, but this point has not been determined. The author is still at work on his subject.

Burial Injuries in the Trenches.—Orth speaks of the comparative frequency of burial by falling earth which has as results shock and severe internal injuries. The displacement of earth, masonry, and scaffolding usually results from shell explosion. Thus a man is suddenly pinned in a certain posture, in one case with knees slightly flexed. After four hours patient could no longer feel his legs and was not dug out until eight hours had elapsed. As the trench was still under fire, he could not be moved to the hospital until seventeen hours after his accident. In this case only the legs suffered, because the man was merely caught in the scaffolding. Another soldier was covered as high up as the

navel, but retained some leeway of movement in the trunk and limbs. After extrication he was found to be intact in the trunk and in the joints of the extremities, the muscles being the tissues to suffer most (this was also true of the first patient). These accidents affect chiefly the calf muscles, and the resulting contractures leave the patients crippled, with an equinus gait. Microscopic biopsy shows that the muscle undergoes a special type of injury in these cases, involving degenerative phenomena. The changes have been likened to those of ischemic contracture produced by tight bandages; but the author states that such a condition, which is due primarily to anemia, cannot explain all the phenomena. In the more severe cases there is more or less crushing, comminution, laceration, compression at a single point, with resulting necrosis and efforts at regeneration.

Le Bulletin Médical.

The Fecal and Urinary Peril at the Front.—Bonnette states that because of the siege-like character of the present war, with troops almost stationary, unusual precautions are required for the disposition of excreta. Man is a poison to man through the presence of the latter, and no amount of preventive inoculation can take the place of sanitation. Among the precautions included under the latter head is the sterilization of water in barrels by Javelle's solution; the drilling of new wells and their supervision; the incineration or burial of filth of all kinds; the removal of dunghills; the whitewashing of habitations; the extirpation of lice and rats; the daily cleansing and sweeping of trenches and shelters; the frequent changing of loose straw and straw-beds in the subterranean posts; the supervision of privies and urinals, etc., etc. Accumulation of fecal matters furnishes the greatest peril. Some sanitarians advocate the use of long, shallow furrows around the towns, without burial. The feces, exposed to the light and air as well as to the soil, rapidly disappear through nitrification. The surface water is not polluted. Admitted disadvantages are the smell and the likelihood that torrential rains will flood the environment. Even worse is the attraction of flies with the possibility of fly-borne diseases. This disposition of feces is satisfactory in the case of troops on the march, but not in trench warfare. Portable receptacles (half-barrels) covered with wooden seats are recommended by others. As fast as these are filled they may be dumped in large pits. This idea is sound in theory but not practicable. The receptacles are never dumped until they overflow. They are provided with handles and carried about, so that they continually slop over. Moreover, should they come into common use many barrels would be taken from the regular supplies, and the price would soon go up. Much more practicable are deep pits boarded over to serve the purpose of fixed privies. The covers are perforated with holes, with hermetic lids, which serve to exclude flies. Such pits must be built far removed from wells. A shelter is constructed over them, open only in front. In loose, sliding earth the vaults should be coffer dammed. There is a great variety of construction described in this connection. Small, portable cabinet apparatus provided with tin pails may be used. The permanent vaults may vary in accordance with the number of people to be accommodated at a time, and may be constructed with the same care as privies for barracks, with brick vaults or waste pipes. The troops should be compelled to use these privies, and if, under cover of darkness, they avoid making the necessary journey must be disciplined. While much urine finds its way into the privies, separate portable tin cans with freely moving handles are provided at convenient stations which are indicated by signs. These are emptied every morning and then disinfected with cresyl or other substance. A zinc gutter placed at a slight incline along the side of a wall is also much used, the urine being carried to a receptacle. There appears to be nothing new in any of these devices and nothing peculiar to warfare.

October 23, 1916.

Modifications of Cardiac Murmurs Under the Influence of Ocular Compression.—Lauboy and Harvier sum up an article on the subject as follows: The effects of ocular compression vary and are at times contradictory, as far as stethacoustic translation is a guide. Nevertheless, we obtain the impression, even in the absence of graphic proof, that compression of the eye profoundly modifies the cardiac contractions. Even electrocardiography throws no light on this subject as a whole. That the reflex arc is complete in the test is certain. Compression is at once followed by a rhythmic response, and there are also certain other responses connected with the contraction of the heart. Nevertheless, the finds differ not only in different subjects but in a single individual. A phenomenon of this sort, in which every individual test may be peculiar, must, of course, disconcert the clinician and cause him to renounce it as a practical measure. The valvular lesion which provokes the murmur does not comprise the total pathology of the heart, but when due to organic disease it speaks without uncertainty, even if at times in a feeble voice. We have only to hear it to know how to make it speak and to incite it to speak. Hence the authors' test may prove of value in the individual case.

Anaphylaxis.—Soula endeavors to sum up briefly the entire doctrine to date of anaphylaxis. As originally formulated by Richet in 1902 it was a very simple affair. He was then dealing with a single poisonous substance. At present, after enormous research which has led to complicated conclusions, there is a tendency to return to Richet's primitive hypothesis. Thus the attempt to extend the production of anaphylaxis to nonproteid substances has been recalled. Richet would do away with the belief that anaphylactic reactions are specific and give rise to the formation of immune bodies. The nature of anaphylatoxin is still obscure. The phenomenon known as passive anaphylaxis shows that the primary injection induces some change in the blood. Anaphylactic shock after the second injection shows the great rôle of the nervous system in anaphylaxis. Extracts of degenerated nervous tissue readily sensibilize animals and anaphylactic shock produces peculiar alterations in the brain which renders the nerve substance toxic. After an animal has been sensibilized it shows changes in metabolism along with functional hyperactivity. A sort of proteolysis results, with increased elimination of nitrogen, while the brain lipoids are increased as a result of anaphylaxis, save when they are combined with nitrogen. Phosphorus when not combined with lipoids is increased by anaphylaxis, etc. To sum up in a few words, anaphylaxis seems to be a general reaction of the nervous system. The changes in the blood and fluids are perhaps secondary, and due to neurochemical disturbances.

Female Bleeders.—Castex mentions the extreme infrequency of hemophilia in the female. In the celebrated Mampel family, four generations of 212 individuals, there were thirty-seven bleeders, all males. In certain individual statistics, however, 10 per cent. and even more have been of the other sex. The author describes in detail a case of hemophilia in a girl of sixteen.—*Revista de la Asociación Medica Argentina.*

Book Reviews.

PHYSIOLOGICAL CHEMISTRY. A Text Book and Manual for Students. By ALBERT P. MATTHEWS, Ph.D., Professor of Physiological Chemistry in the University of Chicago. Second Edition. Illustrated. Price, $4.25. New York: William Wood & Company, 1916.

FURTHER acquaintance with this excellent treatise has served only to confirm the praise of it expressed in these columns on the occasion of its first appearance. The time that has elapsed since that date is so short that but little modification has been required in the present edition. The most noteworthy changes appear to be in the section on colloids, in the discussion of which their surface properties receive rather more emphasis, and additional references have been supplied in some instances through the book. This feature of the work is an especially useful one, and the extensive bibliographies appended to each chapter make the volume most serviceable for reference. The book is an extraordinarily complete presentation of physiology from the chemical standpoint, and cannot fail to win the approval of every reader.

VENESECTION. A Brief Summary of the Practical Value of Venesection in Disease. For Students and Practitioners of Medicine. By WALTER FOREST SUTTON, M.D., Fellow of the American Medical Association; Member Medical Society of the State of Pennsylvania; Allegheny County Medical Society; Ex-President, Carnegie Academy of Medicine, etc. Illustrated with several text engravings and three full-page plates, one in colors. Price, $2.50. Philadelphia: F. A. Davis Company, 1916.

THE first impression obtained by the reviewer refers to the complete omission of any reference to the work on the same subject by Heinrich Stern which has appeared within two years. The present book was written because there appeared to be a demand for it, according to the author. With Dr. Stern's excellent work on the market, such a demand was perhaps satisfied. The author is, however, unusually well qualified to write on the subject, and the book itself reflects throughout his great practical experience and general information.

TRATADO DE PEDIATRIA. Por el DR. ANDRÉS MARTINEZ VARGAS, Catedrático numerario por oposición de Enfermedades de la Infancia en la Universidad de Barcelona, etc., etc. Tomo I. Fundamentos de la Pediatría, Anatomía, Fisiología, Hygiene, Patología y Terapéutica de la Infancia. Barcelona: T. Vives, 1915.

DR. VARGAS is an authority on pediatrics of international reputation, and a treatise on that subject from his pen is an event in the world of medicine. This first volume of 959 pages carries the reader only through general pediatrics, and if the same thoroughness is to be maintained in special pediatrics at least two volumes of like size should be necessary to complete the work, which represents the fruit of the labors of 33 years in the chair of pediatrics in Barcelona. Over 500 pages are devoted to the anatomy, physiology, and hygiene, and nearly 200 pages to general pathology of infancy. The section on general therapeutics, 146 pages long, seems hardly necessary from the American viewpoint, as most of the material will have to be duplicated elsewhere, and is in general inferior to the preceding sections. But few pages are given on diet, although we should expect to find in this section the entire subject of infant feeding. Normal dietetics is found under physiology, but in practice it is hardly possible to consider diet for the well child apart from that of the ailing child. The several excellent monographs on child development have been utilized freely by the author, and calory feeding in infants and young children receives much attention. The very bulk and thoroughness of the work is evidence enough that the author has drawn extensively on the labors of all contemporary authorities. On the other hand, he appears to have received no assistance from collaborators, so that when finished it will stand as a monument to his life activity.

EXAMINATION OF THE URINE AND OTHER CLINICAL SIDE-ROOM METHODS (late Husband's). By ANDREW FERGUS HEWAT, M.B., Ch.B., M.R.C.P., Ed. Tutor in Clinical Medicine, University of Edinburgh; Lecturer, Edinburgh Post-Graduate Vacation Course. Fifth edition. New York: Paul B. Hocher.

THIS little book is of great practical value. It was written with the view of giving the student a short description of the methods of examining urine, blood, stomach contents, sputum, etc., and well fulfills the purpose. That part of the book dealing solely with the urine is the result of a very thorough revision of the fourth edition of Husband's book on "The Urine in Health and Disease." It is a work that would be of service to all medical students.

DIAGNOSIS AND TREATMENT OF SURGICAL DISEASES OF THE SPINAL CORD AND ITS MEMBRANES. By CHARLES A. ELSBERG, M.D., F.A.C.S., Professor of Clinical Surgery at the New York University and Bellevue Hospital Medical College; Attending Surgeon to Mt. Sinai Hospital and the New York Neurological Institute. Price, $5 net. Philadelphia and London: W. B. Saunders Co., 1916.

THIS book is a notable addition to neurology and seems destined to become a classic in the diseases and surgery of the spinal cord. Dr. Elsberg has divided his subject into three parts. He takes up first the anatomy and physiology of the spinal cord, together with the symptomatology of surgical spinal disease. The anatomy and physiology are necessarily very briefly discussed, but all the essentials are given. One of his chapter headings is rather curiously expressed: "The Normal and Pathological Physiology of the Spinal Cord." Why not "The Physiology and Pathology?" Chapter VII deals with Roentgenology of the spinal column and contains no less than 23 plates showing *x*-ray pictures of various parts of the spinal column, normal and diseased, most of them full-page plates. These are excellent examples of the radiographer's skill. There are some beautiful pictures of fractures of vertebræ, also spondylitis. One of the latter bears the remarkable caption: "The *x*-ray findings were confusing, but did not cause the patient's symptoms." This must have been a relief to the radiographer.

The second part of the book deals with operations upon the spinal cord and nerve roots. In this part the general practitioner will find what is probably the best description of lumbar puncture in the literature. This little operation sometimes has to be done by the family physician, and he is now and then embarrassed by failure; it seems, moreover, to be a difficult thing to find discussed adequately in the literature. Dr. Elsberg devotes nine pages to it, with seven illustrations, all of them helpful. His chapter on laminectomy, rhizotomy, and aspiration of the cord is excellent and, like all the rest of the book, well illustrated.

The third and largest part of Dr. Elsberg's work is devoted to surgical diseases of the spinal cord and membranes and is up to the high standard set by the first part of the book. The chapter on spina bifida is especially good. Comparatively little space is given to bullet and stab wounds of the cord and only one picture is shown, an *x*-ray of a bullet between the first and second lumbar vertebræ, and this comes from the European war. Railway spine is discussed in less than a hundred words—it had better have been left out altogether. Mention should be made of the illustrations, which are superb. There are photographs from life, diagrammatic studies, *x*-ray pictures and, best of all, a number of splendid drawings by Mr. Josef Lenhard from specimens, dissections, and actual operations. In short, all of the subjects discussed in this volume are illustrated so thoroughly as to enhance greatly their perspicuity. The book, aside from its great medical value, is a notable example of the publisher's art.

THE MEDICAL CLINICS OF CHICAGO. July 1916. Volume II—Number 1. Price $8.00 per year. Philadelphia and London: W. B. Saunders Company.

IN this first number of the second volume there are presentations from nine clinics and a contribution on oral infections by T. W. Brophy. A number of cases of diabetes are presented in a sketchy fashion but are followed by a fair discussion of the subject. The contribution on oral infection is excellent and is marked by a sane conservatism. Several of the cases presented from the clinics also involve the investigation of this subject so that its importance is well emphasized. In connection with the presentation of a case of "multiple tubercular serositis" we wish to protest that examples of infection with the tubercle bacillus should be designated "tuberculous" since the term "tubercular" has no specific application. In this same case the clinician expresses surprise that the fluid obtained from the chest should contain an excess of polynuclear cells and thinks there may be some secondary infection. The French have shown that the tubercle bacillus may at times excite a polynuclear reaction and that such infections are usually comparatively severe. There is an excellent clinic on the subject of fluoroscopy of the stomach.

Society Reports.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, Held October 23, 1916.

THE PRESIDENT, DR. FREDERICK E. SONDERN, IN THE CHAIR.

The Treatment of Contracted Pelves, with Special Reference to Pubiotomy.—Dr. A. J. RONGY presented this communication in which he stated that the morbidity associated with childbirth had not been sufficiently emphasized either by teacher or by practitioner. The reduction of mortality and morbidity of childbirth depended upon our ability to properly manage the pregnant state from the thirty-sixth week of pregnancy on to the end of labor. This was especially true in primiparæ. Modern social conditions undoubtedly exerted a pernicious influence upon childbirth. By forcing a great number of young women to the industrial field early in life and compelling them to engage in sedentary occupations, their proper physical development was prevented. Among those of the higher social strata there was a tendency to overtax the nervous system either by overstudy or manifold social duties. The result was a highly sensitive nervous system, incapable of combatting the emergencies of life. These conditions had created new problems for the obstetrician, because of the inability of a large percentage of women to deliver themselves. Hitherto too great emphasis had been laid on the pelvic measurements; it was the relation of the fetal head to the pelvis that must always be taken into consideration. This clinical phenomenon must not be observed at term, when labor had already set in, but careful examination should be made from the time the fetal head was supposed to engage itself in the pelvic basin; this was frequently between the thirty-seventh and thirty-eighth week of gestation. As the head continued to grow it might dislodge itself, so that when labor was about to commence the head would be found floating above the pelvic brim. Had labor been induced at the time the first signs of disproportion appeared it would in all probability have terminated spontaneously. In the light of our present knowledge induction of labor at a period of full viability of the child was not associated with any danger to mother or child. Hospital statistics in reference to the induction of labor were not conclusive and should not be used as a guide. The average hospital patient was not intelligent, and it was often impossible to obtain the exact date of the last menstruation. As a rule, the weight of the child could be properly estimated and labor could always be induced in cases in which the child apparently weighed six pounds or more. Dr. Rongy stated that during the past few years he had induced labor in seventeen such patients, the smallest child delivered being six pounds, eight ounces; the largest eight pounds, two ounces. He felt sure that the morbidity in these cases was greatly reduced and that the lives of not a few infants were saved. Recent investigations by a number of obstetricians proved that the period of gestation varied. It was shown that only 80 per cent. of women went into labor between 270 and 280 days from the date of their last menstruation. A number of women carried beyond their computed time from one to five weeks. When this occurred the bones of the head became harder, the fontanelles diminished in size and moulding of the head during labor could not take place very readily. Furthermore, these infants did not stand labor well, between 15 and 20 per cent. dying during labor. Patients were usually advised to have labor induced when they went ten days beyond the computed date. The great problem in obstetrics was not the management of those cases in which a correct diagnosis had been made early, but those that suffered from a relative disproportion of the fetal head and pelvis in whom labor had already set in. This class of cases were commonly known as the borderline cases. In over 80 per cent. of these patients delivery by forceps would be comparatively safe if they were given the test of labor, but in a small percentage of cases the head failed to engage, notwithstanding strong uterine contractions lasting twenty-four hours or longer. Labor in such instances had reached a stage in which cesarean section as a method of delivery must be eliminated, the mortality of cesarean section in such cases being more than 20 per cent. These patients must be delivered by the vaginal route, either by high forceps, pubiotomy, or craniotomy, depending upon the condition of the child and the parity of the woman. High forceps, except in rare instances, must be eliminated from the category of modern obstetrics. This procedure was unsurgical and its fetal mortality in the hands of the most competent obstetricians over 50 per cent. The invalidism it induced in the mother was too great. Secondary plastic operations on the vault in such cases was almost impossible, because of the extensive cicatrization of old lacerations. High forceps might be resorted to in multiparæ, who suffered from simple flat pelvis in whom the vaginal vault was relaxed, and in such cases they tried to engage the head in one of the oblique diameters. The only indications for craniotomy were in cases in which the child was dying or dead, and in cases in which attempts at high forceps delivery had failed after a number of applications. Craniotomy ought never be performed when the child was fully viable. Cases brought to the hospital after having been in labor from twenty-four to thirty-six hours, with a history of having been examined frequently, presupposed infection and one was compelled to resort to the method which was least dangerous for the mother, and at the same time offered the greatest margin of safety to the child. For this class of patients pubiotomy became the operation of choice. Pubiotomy should never be performed when the diagonal conjugate was less than 7.5 cm., or when the disproportion of the head and pelvis seemed to be too great. The sacroiliac joint was always injured when the separation of the cut ends of the bones was too great. Cesarean section should be made the operation of election, pubiotomy the operation of emergency. Pubiotomy had the advantage over any form of Cesarean section that the patient was not left with a scar in the uterus, which might permanently weaken the uterine wall. The writer's experience with pubiotomy consisted of twenty-eight cases performed at the Jewish Maternity Hospital during the past seven years. This was the second largest series in this country. This operation was never undertaken unless the head was partially engaged or showed a tendency to engage, the cervix fully dilated and fetal heart sounds regular and of good quality. That the field for this operation was small was demonstrated by the fact that it was only resorted to eighteen times in over 9,000 indoor cases. Of the twenty-eight mothers, twenty-seven were discharged from the hospital between the fourteenth and forty-eighth day, the average stay being twenty-one days. One mother developed gangrene of the toe on the tenth day and finally died. All the children were born alive, but not all survived. Eight died at times varying from three hours to twenty-four days after birth. The chief objection to pubiotomy was the complication that might be encountered during its performance. It should never be undertaken by one who had not had proper training in obstetrical surgery. The danger of injury to the bladder and urethra was very great. In only one case, however, in this series did sloughing of the bladder wall occur. Communicating tears of the vagina occurred in six cases, but were readily repaired. Hemorrhage and oozing from the cut ends of the bones was always controlled by pressure and packing. The gait was somewhat impaired temporarily in six patients. Injury to the sacroiliac joint could be avoided if the thighs were properly held by two assistants in order to prevent too much separation of the cut ends of the bones. The partly open method of Doderlein was followed in twenty-one cases, while in the remaining seven cases the open method was used. Dr. Rongy presented a brief history of these cases, from which he said it might be observed that nearly 60 per cent. of the patients were multiparæ, whose previous labors were complicated and resulted in the death of the children. The vaginal vault in these cases was lacerated and relaxed. The Gigli saw might also be used as a prophylactic measure in cases of breech extraction, in which some difficulty was expected in the delivery of the head; the bone could be quickly severed in order to permit the head to pass through.

Dr. GEORGE L. BRODHEAD said that Dr. Rongy had brought up many interesting points. He said there was practically no danger in the induction of labor, and while he thought that the procedure was comparatively free from danger, one might get a prolapsed cord or malposition. Craniotomy was a comparatively safe procedure so far as the mother was concerned, but it had been abandoned in cases in which the child was viable and in good condition. By a careful examination

they could determine the size of the child quite accurately, but in fat women, and where there was hydramion this could not, as a rule, be done. It was undoubtedly true that some women did go beyond the normal period of gestation, and in these patients the advisability of inducing labor should be considered. They did not induce labor now as often as they did ten years ago. They had found that with proper diet the patient might be able to go to term, but in some instances labor must be induced at the eighth month. He could not agree with Dr. Rongy that labor should always be induced when the patient apparently went ten days beyond term. The question was simply one of relative proportion between the head and the pelvis. The high forceps operation was a dangerous procedure, especially in primiparæ, and must be undertaken with a great deal of caution. Craniotomy should not be considered if the child was in good condition, and one hesitated to do a Cesarean section in possibly infected cases. Dr. Brodhead thought that Dr. Rongy was to be congratulated upon the results in his series of cases and his figures were in accord with those of Dr. Williams of Baltimore, but personally he felt that, taking into consideration both the morbidity and mortality to mother and child, they would get better results with the extraperitoneal Cesarean section than with pubiotomy, but at the present time they were not in a position to state with authority which of the two operations should be performed.

Dr. GEORGE W. KOSMAK said that he had performed pubiotomy in four cases, the last three years ago. Since that time he had not seen a case that offered the proper indications for this operation. In three of these cases they obtained living children; the fourth case was operated upon after the application of the forceps and there occurred a submucous rupture of the sphincter ani. This was not discovered until after the woman got up and found that she had no control over her bowel movements. One of the great problems in obstetrics was the borderline case, in which the proper diagnosis had not been made or where there had been a lack of judgment on the part of the physician. In these cases the women were formerly allowed to go into labor and to do the best they could. If the child could not be delivered, craniotomy was resorted to, but fortunately that time was past. Dr. Kosmak was glad that Dr. Rongy had taken such a conservative view with reference to the scope of pubiotomy. This was a procedure that should not be undertaken unless the proper means were at hand for carrying it out in a correct manner. It was a good thing to wait until the head became engaged. As to permanent enlargement of the anterior-posterior diameter of the pelvis as a result of pubiotomy, he had made repeated examinations after this operation, and they failed to show any increase in this diameter. He had also found that bony union might take place. He had come to feel that the vaginal examination played a small part in infection and he had seen Cesarean section done where no vaginal examination had been made, and the woman became septic. He did not believe that the infections were due to the vaginal examinations altogether. If the infecting organisms were in the vagina then they probably got infection.

Dr. RALPH WALDO said that a few years ago this operation was quite popular. Dr. Rongy's paper brought out clearly the indications for pubiotomy. It was indicated for the emergency type of patients and was not an operation of preference. When the head was engaged and there was apparently a slight disproportion between the head of the child and the maternal parts, it might be advisable to resort to pubiotomy. Pubiotomy was indicated in a very small percentage of cases.

Dr. A. J. RONGY, closing the discussion, said that he did not come to advocate any single method of delivery, but only to attempt to show how better results might be obtained in cases of labor if they were properly watched and if indications and contra-indications for a given procedure were carefully studied. He wished to bring to the notice of the medical profession that if a woman was carefully observed from the thirty-sixth week of pregnancy to the end of labor, that many radical operative procedures would be avoided. It did not seem fair and reasonable to the average pregnant woman to neglect her during the most delicate period of her life. The usual practice followed by a great number of physicians to examine the patient once at the time she called on the doctor to make arrangements for the delivery could not be too strongly condemned. In answer to Dr. Kosmak he said that in their cases they had no permanent enlargement of the pelvis after this operation and that the union was fibrous in two-thirds of the cases. He did not wish to be misunderstood on the question of induction of labor. He did not perform it unless signs of disproportion of fetal head and pelvis began to appear. Induction of labor could be used as a prophylactic measure after the thirty-sixth week of pregnancy only, otherwise the life of the child was endangered.

Notes on the Diagnosis of Abdominal Distention in Children.—Dr. LOUIS FISCHER read this paper. (See page 932.)

Dr. HENRY KOPLIK said that he saw a good many cases of distension and usually these were referred to the pediatrist only when the diagnosis was difficult. In a case of intussusception with distension, it was difficult to make the diagnosis, because when the distension developed there was no tumor, or the tumor disappeared, and then they must make the diagnosis not only on the abdominal but on the general condition. The cases of distension one met with in connection with pneumonia were puzzling, and it was sometimes difficult to say whether the case was one of peritonitis or of lobar pneumonia. Abdominal distension sometimes decided the issue of a case of pneumonia and was sometimes the final symptom. The pneumonia might not be of great extent and the physician thought he was dealing with a peritonitis; at the same time they might have a pneumonia and a peritonitis. The causes of distension was sometimes very obscure. The diet might have something to do with it, and also the diaphragm where there was a local inability of the gut underneath the diaphragm to expel flatus.

Dr. MAX EINHORN said that the most cases that he saw in children had to do with partial chronic intestinal obstruction. If they saw a stiffening of the bowel or a peristaltic wave then the diagnosis was easily made. The distension might be due to a tuberculous peritonitis and, in some cases, was probably due to intestinal fermentation.

Experiences in Bone Surgery in France.—Dr. FRED H. ALBEE spoke on this subject, which he illustrated with lantern slides. He said that at the present time the chief feature of the war was the surgery of the bones, tendons and nerves. It took an immense amount of time for these septic war wounds to clear up under their older methods of surgery. He hoped to emphasize the fact that this was not the case with the Carrel-Dakin method of sterilizing wound. In many of the war wounds there was a great amount of lost tissue, and when such wounds were treated by the Carrel-Dakin method, the results were most remarkable. The granulations were a deep, healthy red, the edges of the wounds were not inflamed, and the skin was not indurated or sensitive and would slide about the wound very readily. These wounds looked different from any he had ever seen. When a case came from the front the first step was to look for foreign bodies and to localize them. For this the fluoroscope was used and the foreign body charted. The surgeon then went in and took out the foreign body and all the lacerated tissue was trimmed away carefully. Then the fenestrated rubber tube, either covered with gauze or not, was fastened in the wound, and sutured or not sutured. The tubes were laid so that the gauze might be kept saturated with the solution all the time. The reservoir was so arranged that by turning a stop cock the solution could be fed into the tubes. Just enough was allowed to flow in to keep the gauze saturated to the proper degree. A thick coat of yellow vaseline was applied around the wound. In some wounds a system of tubes was used. If the wound was a stump, it was soaked in the solution. Bacteriological examinations of the wounds were made every second day, taking a smear from the worst part of the wound. When only one or two bacteria were found in the microscopical field, the wound was closed. The microscopical appearance of a wound was not to be trusted as an indication of the time it might be closed. By this method of treatment the percentage of primary unions had been over 95 per cent. This method of treatment was applicable to compound and communited fractures as well as to flesh wounds. Dr. Albee demonstrated with the aid of motion pictures his method of putting in bone grafts, which was so effective in restoring limbs from which large portions of bone had been lost. These bone grafts were being used a great deal in jaw surgery.

Dr. H. H. M. LYLE showed colored photographs of wounds that were treated by the Carrel-Dakin method and said the point he wished to make particularly clear

was that this treatment was not merely the employment of a certain antiseptic, but a plan consisting of an immense amount of detail. There was no pus in these wounds and there were no inflamed edges. By the older methods it took about three months, sometimes much longer, to heal up a compound fracture; by this method most of these wounds were healed in from twenty-eight days to six weeks. Out of 450 cases treated by this method and sutured up, there were only six failures and these were not bullet wounds, but the more severe war wounds. Depage reported 137 cases with two failures, eighty compound fractures without a drop of pus. Pus had been practically abolished in that ambulance.

Dr. Samuel Lloyd said that they were all learning and he felt that it was well to have these things brought home to them, because they might have to use them and possibly sooner than they expected. They sent nurses to the Mexican border who wrote that they had 550 patients in the hospital. Only a very few of them were paratyphoids and dysenteries, the rest were gun-shot wounds and fractures. The fractures were the result of riding untrained mules and horses, and the gunshot wounds from trying to learn the use of the new automatic pistols.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON OBSTETRICS AND GYNECOLOGY.

Stated Meeting, Held April 25, 1916.

Dr. George W. Kosmak in the Chair.

Degenerating Fibroid with Marked Toxemic Symptoms.—Dr. Solomon Wiener reported this case and presented the specimen, which consisted of the uterus with adnexa and a large submucous fibroid. In the fresh state the uterus was the size of a five months gravid organ and the fibroid was as large as a grape fruit. The tumor was held under great tension. On cross-section it showed marked edema with softening. It was deep purple in color and contrasted strongly with the pink color of the uterine musculature. It showed irregular areas of deep red, yellowish, and gray discoloration. The pathological report was fibromyoma showing edema and beginning degeneration. The patient from whom this specimen was removed was forty-five years of age, and had had six children and one miscarriage. A year before she had been operated on for acute appendicitis. For about two months before coming under the writer's care she had been bleeding every two weeks, the amount of blood lost being about as much as at the normal menstrual periods. About four days before her admission to the hospital she had been seized with severe pain beginning in the left lower abdomen. This persisted, and later radiated to both groins and sides. The day before operation the patient appeared very ill, much more so than was indicated by her pulse of 120 and temperature of 100.8° F. Physical examination showed marked tenderness over the lower abdomen with voluntary rigidity. Bimanually a large mass could be felt filling the hypogastrium and extending from the symphysis half way up to the umbilicus. The mass was firm, tender, and somewhat elastic. The uterus could not be felt separately from it, and the cervix apparently moved with the mass. Because of the thickness of the abdominal wall an absolute diagnosis could not be made. However, the indication for operation was clear. A simple supravaginal hysterectomy was performed. The patient required stimulation while on the table and for twenty-four hours afterwards. Her subsequent convalescence was uneventful. The chief point of interest in the case was the marked toxemia with the relatively slight degenerative changes in the tumor. The submucous character must have been the reason for the marked absorptive symptoms and toxemia. This class of tumors must be regarded as truly urgent, for the moment that infection of degenerative changes occurred the patient's life was endangered.

Examination of Semen with Special Reference to Minor Defects.—Dr. William H. Cary of Brooklyn read this paper. He said the frequency with which male sterility resulted from the lesser degrees of seminal defect was not realized, nor were the pathological conditions of the semen upon which sterility depended well understood. Proof of this was found in the literature which was very scant on this subject, especially in this country where the examination and study of semen had been much neglected. This might have been due, in part, to the unpleasant nature of the work, but more particularly to the difficulty encountered in securing properly collected specimens for examination. While always eager to claim his share of glory in the production of his offspring, a man was most reluctant to share any responsibility for failure. The study of this subject had been seriously handicapped by the almost universal assumption on the part of the laity that in the event of a childless marriage the wife was wholly responsible. It was not difficult to understand why such an erroneous impression had prevailed so long. In the male, ability to copulate and the normal ejaculation were regarded as sufficient evidence of his power to procreate; while in the female, the process of ovulation was an obscure one and, therefore, more readily suspected to be at fault. It was significant that the more study and observation this subject received, the higher was placed the percentage of male sterility. In countries where venereal diseases were more prevalent than they were here, observers had placed the proportion of cases in which the male was at fault at a surprisingly high figure. Most American writers place the male responsibility at from 15 to 25 per cent., which Dr. Cary believed to be a too conservative estimate. In cases of absolute sterility, the number in which the husband was at fault must be high, at least 1 in 3, for the sexual hygiene of the woman before marriage was usually better than that of her mate, and there was no real evidence to prove that the physiological processes involved in the production and delivery of the healthy ovum were more complicated or less often successful than was the secretion and emission of normal semen. At the present time it still seemed advisable to seek first the cause of a sterile marriage in the female. It must be stated, however, that to conduct long and exhaustive gynecological treatment and ultimately to offer a hopeless prognosis without having investigated the reproductive powers of the husband was neither fair nor scientific. In general the fertility of the semen depended upon the presence of (1) mature living spermatozoa (normal cells), and (2) a normal secretion to maintain the vitality of the cells until such time as they meet the ovum. The opportunity to secure the semen for examination presented itself oftenest to the gynecologist, and he should be equipped to make the examination as a routine part of the investigation of sterility. The most satisfactory arrangement for an examination was made by conveying the necessary implements to the home of the patient and making the observations immediately after conclusion of intercourse. The most common cause of sterility in the male had been formerly attributed to the absence of spermatozoa in the semen, the most common cause of which was gonorrhea. In a very large proportion of the cases this condition resulted from a unilateral or, more often, a bilateral epididymitis. Another cause sometimes responsible for the disappearance of spermatozoa from the semen was exhaustion due to abnormal demands upon the sexual organs. The use of the *x*-ray had figured prominently as a cause of azoospermia. The fecundating power of the semen might be greatly lessened by the presence of many malformed spermatozoa. Such cases were not rare. Inasmuch as it was not determined definitely at what time the ovum was freed from the ovary, and in view of the physiology of ovulation, it was obvious that the successful completion of the process of fecundation required that the spermatozoa should not only have the power to migrate to the interior of the uterus or tube, but that their vitality must be sustained until the ovum was presented. To this end Nature produced thousands of fecundating cells that one might survive to perform its complete function. Under normal conditions the vitality of the spermatozoa was remarkable. At the same time they were extremely sensitive, perishing promptly in tap water and in faint lactic acid media, or under other minor changes in their environment. One of the less common forms of seminal defect was that resulting from too great density of the semen, in which case their motion is sluggish and of short duration. Of still rarer occurrence were those cases in which the fertilizing elements of the semen were destroyed by the presence of pus and blood in the semen. The available data justified the assertion that pus was destructive to the evolution and life of the sperm cells, and this probably explained in part the sterility of women who suffered from endocervicitis and endometritis. There was some difference of opinion as to the effect of blood upon the seminal elements, but the writer's observations showed that spermatozoa would live four or five hours in blood which corresponded to the observations of Robin, while

Dieu had shown that when blood had mixed for some time with the contents of the seminal vesicles, the sperm cells were reduced in number or were entirely absent. The treatment of male sterility had been less studied and had received less attention than any other part of the subject. Many of these cases could be helped; others were hopelessly incurable. If it was suspected that the cause of sterility was to be found in the husband a detailed history must be secured. And if it was found that the patient was sterile, his case might be classified as coming under either one of the two groups *impotentia cocundi* or *impotentia generandi*. Only the latter group was under consideration. The treatment of some cases consisted chiefly in regulating the sexual life, correcting unwholesome habits, or adopting measures to check involuntary seminal loss. Sterility might be due to defective semen dependent upon a debilitated condition incident to an overactive business career, and might be cured by proper regulation of life and habits of the patient. Sterility due to obesity might be cured by treatment directed toward lessening the obesity. Azoospermia resulting from chronic inflammations or exudates due to a remote gonorrhea was very unsatisfactory to treat; these cases would improve and might be cured if placed in the hands of a genitourinary specialist. Azoospermia, when present in patients with a negative venereal history, should excite a suspicion of some chronic constitutional disorder. It must not be forgotten that absence of spermatozoa might occur in such rare conditions as cryptorchidism, congenital absence of the testes, congenital deficiencies of the excretory passages, and malignant diseases of the genitals. When dependent upon such conditions the azoospermia sterility was absolute and permanent. Tubercular disease of the testes and syphilitic orchitis rendered the prognosis very unfavorable. Dr. Cary illustrated his paper by lantern slides showing forms of normal spermatozoa and various types of deformities.

Dr. Max Hühner said he did not sympathize with the methods of collecting the specimen which Dr. Cary employed. It meant more work, was rather complicated, and was not as accurate as taking the specimen from the cervix. The condom specimen might be perfectly normal and the sterility due to hypospadias, epispasias, or the fact that ejaculation occurred before the penis entered the vagina. He simply had the woman come to his office after coitus and took a specimen from the cervix by means of a platinum loop, and if live spermatozoa were found one could tell right away whether the secretions of the vagina were harmful or not, and whether the husband was all right. He had found that the presence of pus in the semen was not an absolute test as to its power to fecundate. He had found that they were not killed in the presence of gonorrhea, and a man with gonorrhea might impregnate and give gonorrhea at the same time. The test for viability was not an absolute test either, because the semen under the microscope was not in its natural condition, but these same spermatozoa taken from the vagina after two or three days might still be active, while they might die in a very short time under the microscope. Nothing was known about the viability of the spermatozoa in the Fallopian tubes. In every case in which the tubes and ovaries were removed, we should find out when the last coitus had taken place and make an examination for living or dead spermatozoa. In this way we might get some information as to how long it took the spermatozoa to reach the tubes.

Dr. Henry C. Coe expressed the opinion that the profession had been entirely too ready to resort to curettage in cases of sterility and to make positive promises as to the success of this procedure, and said that he was opposed to subjecting a woman to an operation for sterility until the condition of the husband had been determined. The suggestion that an examination of tubes that had been removed should be made in order to determine the possible presence of spermatozoa and the length of time during which they retained their vitality was a very good one, and he did not think this had been done.

Dr. Thompson T. Sweeny said he was interested in this subject because he had a large clinic of Jewish women to whom sterility was a disgrace. In treating them for sterility he did so only until any pain they had might be relieved or any tubal condition that was perceptible to the touch was relieved. It was often difficult to get a specimen of semen from some husbands, due to their ignorance in believing that such a request was a reflection on their manhood. It had been a point of great interest to him to find that men who appeared absolutely healthy or powerful or robust and who had never had gonorrhea, mumps, or any affection, were sterile. In collecting a specimen of semen he had made use of the condom tied and dropped into a vaseline bottle containing water at 100°. In cold weather this bottle was wrapped in flannel and paper to retain the heat. When the husband was intractable he had the wife come to his office after coitus and took a specimen from her vagina. Many women had an occlusion of the tube sufficient to prevent pregnancy, but too slight to be detected by digital examination. Such a condition frequently yielded quickly to local treatment.

Dr. William H. Cary, in closing the discussion, said he had not considered the subject of impotence except to refer to it as included in the general subject of sterility. Dr. Hühner, in speaking of methods of examination, had taken an entirely erroneous viewpoint. In taking a specimen from the vagina he might find the spermatozoa dead, having been killed by the hyperacidity or other chemical changes in the secretions of the vagina; whereas, if he had taken the specimen directly from the male it might have shown normal vitality. Therefore, a specimen from the vagina or cervix was not a fair test of the fertility of the male element. Dr. Cary said he also had been interested in finding a condition of sterility in powerful men with a negative venereal history. He had found a condition of sterility in clergymen, brokers, and lawyers who were carrying heavy responsibilities, and had found that sending them away on a prolonged vacation and giving them a chance to recuperate improved their semen, and in a number of instances their wives had ultimately become pregnant.

Congenital and Acquired Retropositions of the Uterus, Their Differentiation and Relative Significance. — Dr. Arnold Sturmdorf presented this paper in which he emphasized the fact that our fundamental conception of uterine poise, normal and abnormal, had not as yet attained to any concrete finality, and barring the occasional allusion to the existence of congenital retrodisplacements and their probable dependence upon conditions of general visceroptosis the clinical significance of such displacements, and their diagnostic etiological and therapeutic contrast to the acquired form found no elucidation in the literature of the subject. The wide diversity in the nature of the two conditions presenting practically identical symptoms demanded their clinical differentiation, and such differentiation necessitated a differentiating factor of pathognomonic constancy. In seeking to establish such a pathognomonic factor it was necessary to recognize that the malposition did not represent simply a congenital uterine retroversion but a congenital retroversion of the entire pelvis, with resultant dystopia of its entire contents. Dickenson and Truslow had characterized these cases as the "gorilla type," in which the pelvis was rotated backward and downward, the plane of its inlet making with the horizon an angle more acute than that of the normal type. This flattening of the sacrovertebral angle was regularly evidenced by a corresponding obliteration of the normal lumbar curve, and the measure of its resultant approximation to the vertical constituted a pathognomonic index in differentiating congenital from acquired retrodisplacements of the uterus. In order to obtain this measurement the patient, with back exposed, assumed her natural standing attitude, while the edge of an ordinary 18-inch desk ruler held vertically in contact with the most prominent spinous processes of the dorsal and sacral convexities spanned the intervening lumbar hollow. The distance in millimeters from the deepest point of this hollow to the edge of the ruler represented our index. In an extensive series of observations the index ranged from 12 mm. to 45 mm. An excess of 45 mm. indicated the pathological lordosis and was of more obstetrical and less gynecological importance. An index of 30 mm. made the extreme minimum compatible with normal anteversion of the uterus; from 25 mm. down, the existence of congenital retroversion might be positively predicted in nearly every case prior to its bimanual verification, and this regardless of multiparity and the other complicating factors that obliterated the differentiating criteria. A uterus congenitally retroverted before conception would invariably resume its retroverted position after delivery, when the demonstration of a minus index would reveal the congenital nature of the displacement and exonerate the accoucheur. An application of the lumbar index would establish over one-half of all retroversions, complicated and uncomplicated, as congenital, instead of one-fifth as hitherto accepted. In an abdominal cavity of normal skeletal con-

figuration a true vertical in contact with the sacrovertebral promontory would impinge against the inner surface of the symphysis pubis at its lower border; hence, accepting the principles of deflecting planes which the writer had previously demonstrated as fundamentally applicable to this problem, it followed that every deviation from the normal in the angle of the deflecting surfaces presented by the sacrum and the symphysis must induce a corresponding deviation in the direction of the intraabdominal pressure with resulting visceral displacement, or, in other words, every abnormal pelvic tilt created a corresponding uterine tilt. The upward and backward rotation of the pelvis elevated the pubes and lowered the sacrum, which latter, thus forming the posterior instead of the upper wall of the pelvic cavity, necessarily altered the direction of the sacrouterine ligaments, their horizontal pull tending to hold the uterus backward against the depressed sacrum instead of suspending it from above as in the normal. Furthermore intraabdominal pressure inadequately deflected thrust the loose intesinal coils into the pelvic cavity and against the anterior surface of the uterus, crowding it into the space of least resistance offered by the sacral hollow. The continuous attitude was a strain on the sacroiliac joints, the erector spinæ and iliopsoas muscles which induced pelvic symptoms that simulated and were generally attributed to retroversion. Since compensatory retroversion was a compensatory necessity it followed that any procedure which converted such a retroversion into an anteversion converted a compensated into a decompensated visceral equilibrium within the pelvic cavity. The aim of the gynecologist in these cases should be to eradicate all coexisting intrapelvic complications, thus converting the complicated into an uncomplicated case. Hence these cases should be treated on purely mechanical and orthopedic principles. During and complementary to such treatment a properly moulded pessary should be inserted, not with the object of anteverting the uterus but to act as an artificial ledge at the deficient sacral promontory in the deflection of intraabdominal pressure. This would afford much relief during the long period of mechanical treatment.

Dr. Dougal Bissell said he had never been able to determine just what congenital retrodisplacement was. He conceived it as dependent upon structural defects as real as those of congenital prolapse of the entire uterus. As to the difference between congenital and acquired retroversion it might be assumed that in the congenital type the uterus had never assumed the anterior position, while in the acquired type it might be assumed that the uterus had occupied the anterior position at some time. Dr. Bissell said he had never recognized such a case as one of congenital retroversion except in one instance—that was a case that really fitted in with his idea of congenital retroversion. This young woman had a backward displacement of the uterus and a prolapsed double kidney which filled the entire right side of the pelvic cavity to such an extent that it would have been impossible for the uterus to have assumed the normal position. In this woman he replaced the kidney but neglected to employ operative measures to correct the retroflexion. A pessary was worn for some time but did no good. Later the woman married, conceived, and was delivered of a normal child.

Dr. George Gray Ward said he had not been present to hear the paper, but felt that when one had a case of retrodisplacement he must not assume that it was necessarily the cause of backache, for backache, as they all knew, might be associated with faulty posture, irrespective of the position of the uterus. As to the congenital type of retroversion he thought that it was not common and that when one did find it there were not many symptoms associated with as a rule as one found in retroflexion or retroversion with subinvolution following abortion or labor. In congenital retroversion one might find a short anterior vaginal wall and a faulty implantation of the cervix, and the position of the cervix could not be corrected without correcting the short vaginal wall by an operation such as had been suggested by Dr. Reynolds of Boston. All of these cases must be studied individually and the type of operation chosen which met the requirements of the individual case. Too often a man had a fad, some particular operation which he applied to all cases of retrodisplacement. If the uterus was freely movable and could be replaced the Alexander operation was suitable, especially if the woman had borne children and the ligaments were well developed. The Webster-Baldy operation was suitable where there was an adherent retrodisplacement with denuded surfaces on the posterior wall of the uterus. Here the round ligaments might be used to cover up the raw surfaces. The same might be said of the Coffey operation when one had a denuded surface on the anterior wall. When the round ligaments were elongated and in good condition Dr. Ward said he did a Simpson operation; this left no loop where the omentum or intestine might become strangulated. Dr. Ward said he did not believe in using the round ligaments to support a straight prolapse. Nature did not use muscle for this purpose, and the round ligaments were muscles. The broad ligaments and the uterosacrals supported the weight, and the round ligaments simply limited the backward excursions of the uterus. It would seem from the anatomical construction of the pelvic organs that woman was never intended to walk upright.

Dr. John Van Doren Young said that a clear concept of a deformity was the first requisite for its correction. One did not have to listen long to this discussion to learn that a clear concept of the displacements under consideration was lacking. Dr. Sturmdorf had cleared the horizon and given some basis for further work along this line. In a series of 6,224 cases of pelvic conditions which the speaker had recently reported over 2,300 showed some type of retroposition of the uterus. This gave one some idea of the importance of this form of displacement. Dr. Young said he had listened closely to Dr. Sturmdorf's paper and he did not understand his statement of congenital versus acquired retroversion. Each one who discussed this subject should say just what he meant by the term he used. About 90 per cent. of our trouble in discussing this subject was due to a misunderstanding of terms, and the large number of operations were due to the faulty conception of the deformity they were trying to correct. From the standpoint from which Dr. Sturmdorf had presented this subject it opened up a wide field; it showed why operations had so often failed and why the gynecologist needed the help of the orthopedist in the correction of these displacements; it showed why with the same technique one operator failed and another succeeded. Dr. Young said he disagreed with Dr. Sturmdorf on one point, and that was that a retroposition of the uterus, a mechanical pathological retroversion with retrocession of the fundus, antrocession of the cervix and descensus of the whole uterus was cured by a pessary or correction of body poise; these methods had failed in every patient he had ever seen. Dr. Young believed we should resort to operative interference after the pessary had failed. Twenty-five years ago they talked nothing but pessaries; within the last five years nothing but operations, and now the pendulum had swung the other way. Dr. Young asked whether a mispoised skeleton might not be acquired as the years passed not by evolution but by a lack of education and development.

Dr. Leroy Broun said it was difficult to fully appreciate the various steps in Dr. Sturmdorf's argument without reading his paper carefully and at leisure. He wondered whether Dr. Sturmdorf meant to include among congenital restroversions conditions associated with a general ptosis of other organs; in the latter condition it would be useless to operate on a displaced uterus when there existed a ptosis of other organs, as of the digestive tract and kidneys. Dr. Broun said he would not operate for retroversion alone when other ptoses were present. When there were symptoms of retroversion, backache, etc., not dependent upon an ill-fitting corset, or in cases in which sterility supposedly was due to retroversion, he obtained successes from operative procedures oftener than he got failures.

Dr. Samuel Bandler said that if Dr. Sturmdorf's method of getting this index would in the future show them the cases of congenital retroflexion without it being necessary to make a rectal and vaginal examination he would have added greatly to their gynecological knowledge. If they had practised gynecology and failed to recognize a position of the body as typical of malposition of the uterus, such as that to which their attention had been called, they had at least now been shown the A, B, and C of uterine displacement. It did not seem to him that it had proved any point. Dr. Bandler said that for a long time he had used the term retrodeviation to signify a simple retroflexion or retroversion. A retrodisplacement on the other hand was a change from the normal due to a shortening of the uterosacral ligaments. Lf Dr. Sturmdorf meant a retroflexion he would discuss the subject from that standpoint, but what was wanted was the right name for these conditions. The type of retrodeviation that took place in a nulliparous woman was entirely different from that in a woman after her first labor. This was a reason why the practice of ob-

stetrics was of value to the gynecologist, and explained why a large number of operations for retrodeviation failed. They all knew that labor was responsible for the acquired retroflexions. Whether their efforts at correction of the retroflexion succeeded or not depended on the ultimate position of the cervix. When the cervix was low down, it was natural for the fundus to fall backward, and corrective or operative measures must lift up the cervix and replace the fundus forward. In a large number of congenital retrodeviations the anterior vaginal wall was extremely short. These were the hardest cases to replace with a pessary, because the pessary could not put the cervix high up, and as a consequence the fundus fell back, because the short vaginal wall would not permit the uterovesical ligaments to stretch. The uterosacral ligaments were too loose, and here, if one did an Alexander-Adams operation and shortened the round ligaments, the result was that the uterus simply doubled on itself and would not stay in place. The proper thing to do in such a congenital case was to open the abdominal wall and to place the uterus in such a position that the fundus could be fastened to the abdominal wall, even three-fourths of the way to the umbilicus and then the doubling up would not occur as in the Alexander operation. With so many different forms and causes of retrodeviation Dr. Bandler doubted very much if the acceptation of one sign was going to help them very much in a practical way.

Dr. T. Thompson Sweeny said it was generally conceded that the uterus was supported by the uterosacral and uteropubic ligaments. It was evident that in the erect position nature had suspended a body from its base. On all fours it was inconceivable that a woman could have a retroversion, since in that position the uterus was suspended from its apex. Dr. Sturmdorf's paper explained many of the problems of retroversion. One woman physician in Chicago, after studying sixty cases of retroversion without symptoms, concluded that this was not necessarily an abnormal position. These were probably congenital cases in which the pelvic circulation adjusted itself to the malposition. Retroversion with inflammation produced symptoms only when the position interfered with the return of the venous blood. Dr. Sweeny said he found a large number of retroversions in young women which produced no symptoms, and had made it a practice to let them alone, making no effort to correct a condition to which the pelvic circulation had adjusted itself.

Dr. Sturmdorf, in closing the discussion, said that the intimation that he advocated the use of the lumbar index to the exclusion of direct examination in the diagnosis of uterine retroversion was an unwarranted perversion of his position. He had stated distinctly that "with an index of 25 mm. or less, the existence of congenital retroposition might be predicted in nearly every case, prior to its bimanual verification." The general trend of this discussion established one fact if nothing more, that congenital retroversion was known in name only. It was this fact among others that prompted and justified his present communication. Dr. Sturmdorf said he had utilized the general term retropositions advisedly, dividing the cases into complicated and uncomplicated, because such a division was more conducive to clarify than the textbook classification of versions, flexions and retropositions, adherent, nonadherent. He had distinctly stated that the usual operative measures applied to uterine retroversions and retroflexions were applicable to the acquired but not to the congenital form of uterine displacements. He was not discussing the relative values and indications for retroposition operations, but the recognition and differentiation of a class of retropositions in which any and all operative intervention was imperatively contraindicated. The method and means advocated for this differentiation were so simple that the verification or refutation of the statements he had made were within the reach of all.

Radical Extirpation of the Lacrymal Sac.—Carrases has performed this operation 110 times, using the Seidel technique. The principal factor in this operation is the avoidance of hemorrhage, which must be controlled sufficiently to permit of a deliberate and careful dissection. The addition of adrenalin to the novocaine is necessarily of great value, and later pledgets of gauze soaked in some local hemostatic may be used as occasion arises. Save when hemophilia is present a good hemostasis is possible before the actual dissection of the sac.—*Revista de la Asociación Medica Argentina.*

Miscellany.

A Student and Victim of the Plague.—In a recent issue of *Health News*, published by the U. S. Public Health Service, an account is given of John Daniel Major, a seventeenth century student of the plague. He was born August 16, 1634, in Breslau, and was a physician and naturalist of no mean ability. Bitten early by the wanderlust, he studied at Wittenberg, took courses at many of the schools in Germany, and finally went to Italy where he received the degree of doctor of medicine at Padua in 1660. Returning to his own country, he resided for a short time in Silesia, and in 1661 married at Wittenberg, Margaret Dorothy, a daughter of the celebrated Sennert. The following year, his young wife was stricken with plague and died after an illness of eight days. Distracted by his loss, Major wandered up and down Europe studying plague wherever he found it in the hope that he might discover a cure for the disease which had bereaved him. Spain, Germany, France and Russia were visited by him. He settled in 1665 in Kiel, where he was made professor of botany and the director of the botanical gardens. He made frequent voyages, however, always in quest of the remedy for plague. Finally in 1693, he was called to Stockholm to treat the queen of Charles the Eleventh, then ill with plague. But before he could render her any service, he contracted the disease and died on the third of August.

Child Labor.—At the request of the Massachusetts Board of Labor and Industries, Assistant Surgeon M. Victor Safford of the U. S. Public Health Service was detailed by the Federal Government to cooperate with the State authorities in a study of the effect of employment in various occupations on the health and physical development of children now permitted by law to work therein. A report of this study with respect to the cotton manufacturing industry of Massachusetts has just been published by the Federal Government as Public Health Bulletin No. 78, entitled "Influence of Occupation on Health during Adolescence." The physical condition of over 600 boys between the ages of 14 and 18 employed in this industry in different parts of the State received careful study.

A considerable proportion of the younger boys and also of those over sixteen were undersized and physically undeveloped for their ages while those between fifteen and sixteen averaged larger than other classes of boys of their age with which comparisons were made. This fact is explained by the accumulation in the mills of strong boys waiting to reach the age of sixteen to go into permanent "full time" occupations. The presence of a noteworthy proportion of undersized boys is not ascribed to the effects of the occupation but to the fact that the cotton mill offers one of the few chances of employment for undersized boys. Evidence of injurious effects of their work or working conditions, even of the temperature and humidity of the mills, on normal boys was seldom found. Comparatively few cases of dangerous diseases were discovered. There was, however, a wide variety of defective conditions disclosed by the investigation, many of them of such a character as to impair seriously the future health and economic usefulness of the individuals concerned if not remedied.

A CONSIDERATION OF THE INTESTINAL TOXEMIAS FROM THE STANDPOINT OF PHYSIOLOGICAL SURGERY.*

By JEROME MORLEY LYNCH, M.D., F.A.C.S.,
AND
JOHN WILLIAM DRAPER, M.D., F.A.C.S.,
NEW YORK.

(From the Clinic of Surgical Gastro-Enterology, New York Polyclinic School and Hospital, and from the Laboratory of Surgical Pathological Physiology, New York University.)

THE alimentary canal is the one single system in the body. All others are bilaterally symmetrical. Why is this so; are there compensations for the apparent deficiency, or does it mean that nature has felt this the oldest of all the systems to be so perfect as to be sufficient to the economy as a single unit? Has this interesting phenomenon any pathological significance? Bichat and others advanced cognate hypotheses a generation ago. Does the length of the canal offer any explanation of its efficiency and what bearing, if any, has the fact that the diameter varies directly with its length? Can any deductions be drawn from the fact that the pars pylorica is well developed long before there is evidence of any fundus? May not priority in origin point to priority in function? Has not the very fact of its amazing efficiency a bearing upon the well-known law that as an organism approaches perfection it tends to self destruction?† In its extreme age, in its refinement of function, we may perhaps seek for some of the fundamental causes of its variations from the normal and for the resultant known generally as intestinal toxemia.

Like the many sects in medicine, each one of which sees truth through its own narrow slit, so also has the subject of autointoxication been approached. Some have considered it a mechanical condition pure and simple; some a neuromuscular one; some a disturbance of internal secretions; some as arising from a vagotonic disturbance; some a psychosis; some, like Adami, consider it a subinfection; some, like Combe, a hydrolytic process of bacterial origin. Non-partisan students are at a loss in seeking the truth from among this maze of authoritative statements, for the partisans are clever and their writings are voluminous.

One thing at least is clear, viz., that the causes are either exogenous or endogenous. The factors operating from without, like misplacements, displacements, obstructions, and bacteria which hydrolyze proteins within the lumen are totally separate and distinct from those of a biochemical nature which probably have their origin in the disturbed conditions in the cells of the intestinal epithelium itself, and are properly endogenous.

*Read before the Jefferson Hospital Medical Society, Philadelphia, January 28, 1916.

†The classic example of this is the extinction of the Irish elk, due to overgrowth of antlers.

What part does the modern surgeon play in this complex problem? To our mind a very large and increasingly important one. *The physiological surgeon is the internist of the future.* This view is not held without dissenting voice for the general conception of the surgeon's place in the therapeusis of the canal, aside from the treatment of acute conditions, is that he may occasionally be of use to remove mechanical obstructions which cause obstipation. Popularly this condition is known as stasis. We hold that this term is an unfortunate one because it implies mechanical rather than biochemical or physiological considerations, which seem to the essayists of far greater importance. This is not a plea against the mechanistic school which plays its important part, but fortunately surgery is no longer divorced from the sciences, having become an integral part of them.* Thus its votaries will give great help in determining the etiology and therapeusis of the non-obstructive, non-static intoxications, in many of which surgical intervention alone avails. This means only that the diagnostician must now think in terms of both medicine and surgery.

The pathology of adolescence begins in utero, and this seems to the essayists one the strongest arguments for eugenics. Whether due to ontogeny or phylogeny needs no further discussion here.

Until birth the child's future is predestined by the forces of nature. In childhood much can be done to correct congenital alimentary defects; at maturity, the individual to a great degree shapes his own career, quite aside from the limitations of his environment. Thus there are three periods—the first, over which we have no control save through eugenics; the second, over which an increasing control will be gained through increasing knowledge of child hygiene and therapeusis; the third, over which control will be gained in direct proportion to the acquisition and diffusion of the truth regarding etiology, diagnosis, and therapeusis. Out of this vast field we have chosen to discuss in detail a few factors relating to the third.

For purpose of comparison we may roughly look upon the stomach as a receptacle which prepares the food for digestion. In action it is analogous to a cement mixer—crushed stone, cement, and water are poured in at one end and without absorption or loss, chyme is dejected at intervals from the other. For is it not in the experience of all to have seen unimpaired digestion proceed in gastrectomized animals or men. It is a specialized morphological adaptation; useful but not essential.

Similarly, as regards the ceco-colon which prepares the food for dejection. Who among us has not seen colectomized men and animals remain in perfect health, all diarrhea being controlled through the assumption of colonic function by it embryological prototype the terminal ileum? Even more sig-

*New York University now grants the degree of Ph.D. in surgery.

nificant is the fact that broken health has unquestionably been restored in human beings after partial or complete resection of the colon. It is far from our intent to argue that these organs have no function, for it is well known that along with all other groups of specialized cells, those of the stomach and colon must normally play an important part in balancing metabolism.

To further complicate the problem of surgical diagnosis and therapeusis, there are compensatory properties inherent in the alimentary canal just as truly as in the heart. A resected stomach may in part reform in six months; an ileac segment transplanted into a colon will shortly assume both the size and in a measure the function of the colon, with the exception of anastalsis; a terminal ileum upon which, by the operation of ileostomy, the function of a colon is suddenly thrown will vicariously assume colonic function both as regards water absorption and fecal storage and dejection; an intestine will thicken oral to an obstruction and in proportion to the load, until, as in the heart, overload begets atonia and dilatation. Thus it is more than ever clear that in the alimentary canal we are dealing with a system which, in part due to asymmetry, in part to extreme antiquity, and to the persistence in it of primordial zymotic reactions long dormant and now superseded by the nervous system, is endowed with many functions, a few of the grosser of which are known, but most of which are utterly unknown. It is a system subject to the utmost variations of form due both to hereditary and to environmental conditions, and which, save the brain, finally is the seat of the most complicated derangements of any part of our bodies. Of the symptoms traceable to this canal one great surgeon has said, "We know so little as to their origin and treatment that we should consider ourselves the fools rather than the neurasthenic patients whom we seek to relieve."

Diagnosis of Adult Conditions.—After all, the diagnosis of adult intestinal toxemias has as its basis the cardinal symptoms diarrhea and constipation. These conditions have been treated empirically from time out of mind, so that it is next to impossible to get either physician or patient to look upon them as symptoms rather than as entities. But progress demands it. As the modern physicist is showing that the supposed elements are really manifestations of a single basic ion, and therefore not in a true sense elemental, so must we modern physicians realize that the ancient disease entities which we have been taught to believe in are often not elements, but are simply symptomatic, superficial and almost always protective manifestations. They are far more numerous than the sixty-odd old chemical elements, being the variable outward expressions of a fundamental disturbance of metabolic equilibrium and of nature's efforts to heal.

It is the old story of the objective method as opposed to the subjective; of function *vs.* form; of biologic laws opposed to empiricism. It is significant that a true interpretation of symptoms has been the best means of improving therapeusis. We are, at best, only beginning to understand that most symptoms are protective and should be encouraged rather than suppressed until the true cause of the underlying disturbance has been found. Think of the efforts to treat fever faints and inflammatory swellings as though they were enemies instead of friends!

There is no field in all medicine more vivid with the truth of all this than that of the diarrheas. Let us urge that all diarrheas and constipations be looked upon as due to an exogenous cause until proved to be endogenous. Exogenous causes are either congenital or acquired. In our experience failure of fusion and departure from the normal migration of the cecocolon play a more important part than the acquired conditions, for they are transmitted by the same laws of hereditary which govern transmission or other dominant characteristics. The common mesentery which results from non-fusion may permit of 180 degrees mesodorsad rotation upon adventitious bands which often support a cecocolon from the parieties constricting the ascending colon and causing a tadpole-like deformity with intermittent partial obstruction, as occurred in one of our cases recently. Such bands are doubtless manifestations of nature's efforts to compensate for the hereditary deficiency. No more potent argument is at hand in support of extensive undergraduate study of comparative anatomy and of research surgery on the lower vertebrates than this. For every graduate should know that from a common ancestor we may inherit departures from our conception of the normal; as, for instance, a mobile duodenum or mesogastrium, such as are found in the dog; non-rotation, non-fused mesentery; an herbivorous type of cecum; infantile cecum; megacecum; absence of sigmoid (quadrupeds have no sigmoid according to Henscher & Bergstrand in Ziegler's Beiträge 56, 1913) or of cecum, and a host of other variants, explicable only by heredity. The teaching of these fundamentals seems to us of far greater use than an ingrinding of the pharmacopœia or of descriptive anatomy.

Bayliss and Starlings "law of the intestines" or myenteric reflex is of great importance in the surgical physiology of the alimentary canal. It consists in the production of a relaxation with inhibition of movements aboral to the spot at which a mass of food is collected and an increase of tone together with more powerful contractions oral to the spot, thus moving the contents onward.

The recent papers by Keith recording the presence of hitherto unknown intestinal ganglia also help to explain many things. But there are certain observations which come to the surgical student of the alimentary canal, who studies his cases from a biological standpoint, which seem to us of special interest and which are not as yet widely recorded.

We have for years contended that death from duodenal or jejunal obstruction is due to an interference with the internal secretory function of the epithelial cells of the gut itself rather than to bacteriotoxic causes This hypothesis is now accepted by most investigators. Now, if this is true of complete obtructions, what diversity of symptoms may not be caused by incomplete obstructions occurring at different levels! Doubtless the complexity of duodenal enzymes or hormones is much greater than that of any other part of the canal, though the subject is far from settled as to details; and this may explain the relative gradation of symptoms and the well-known fact that their intensity varies as the square of the distance from the duodenum or thereabouts. Moreover, what has been accepted for the duodenum may be true also of the colon. This at least affords a working hypothesis to explain the immediate relief from certain types of arthritides, as occurred in one case of our series after developmental reconstruction, and in several reported by Bottomley. We are not sufficiently advanced in a knowledge of the internal secretions to say how important a disturbance of these may be in

the colon, nor, indeed whether they exist, but if we are to believe Pick, even the lowly connective-tissue cell of the colon secrets an enzyme called tyrosinase, which has the property of converting aromatic substances into a pigment closely resembling melanin in appearance. Thus Pick would account for pigmentation of the colon.

Furthermore, this matter of internal secretion of the gut may have an important bearing upon the phenomena which we have noted after ileostomy when there occurs a most marked change in the physical well-being of the patient as sudden and as profound as we have noted in the arthritides after colonic reconstruction.

Previously the clinical changes observed after this operation have been explained wholly on the ground that the proteolytic anaerobic bacteria which Combe and his school have credited with so prominent a part in intestinal toxemia were unable to thrive on the acid media of the terminal ileum, and it is on this assumption that Metchnikoff popularized the value of the fermented milks. Here may be another point of similarity between the physiological mechanism at the beginning and end of digestion. The acid ileac chyme discharged into the alkaline cecum may stimulate the outpouring of enzymes in the lower gut as in the upper. What has been proved true of one is perhaps true of the other and there may actually be an internal secretion of the cecocolon which becomes perverted and autotoxic when motility is disturbed.

Next to be considered is what applied surgery can do for intestinal toxemia.

It is accepted that a definite number of patients suffering from the syndrome of intestinal toxemia have been benefited or cured by operation, after other methods have been tried. What are the procedures which have been in general use? First, ileosigmoidostomy. Second, cecosigmoidestomy. Third, appendicostomy. Fourth, ileostomy. Fifth, plication of the cecocolon and repair of the cecal valve. Sixth, total "Colonic exclusion." Seventh, colectomy. Eighth, developmental reconstruction or right ileo-colectomy. The very multiplicity of procedures is in itself a certain index of our ignorance. What can be said of these operations?

Ileosigmoidostomy has undoubtedly benefited a goodly number of cases. But what are its drawbacks and dangers? We have shown in a previous paper that a dominant anastalsis is often the physiological basis for the symptom constipation. All operations must be planned so as to minimize the effects of this symptom of aberrant physiology and if possible to counteract it. The foremost advocates of this operation admit that because of anastalsis in 10 per cent. of cases a subsequent colectomy is a necessary corrective measure. Further, although we may learn to recognize sigmoidal anastalsis before operation, who can say that it may not develop as a result of this operation itself? The technique, therefore, has a much higher mortality than is usually ascribed to it because of these secondary complications, and is rightly falling into disuse.

Cecosigmoidostomy is deficient both theoretically and in practice. Its employment leaves out of consideration the law to which we have referred, viz., that intestinal contents tend to follow the normal direction of the canal, irrespective of lateral stomata. We again wish to emphasize the importance of this law. We have recently demonstrated a vicious circle in five out of six cases. The following case history is illustrative of all:

Patient referred by Dr. Robert M. Brown of Saranac Lake, New York. Cecosigmoidostomy was performed for the relief of intestinal toxemia eighteen months ago by a thoroughly competent surgeon. After the operation the symptoms were aggravated and *x*-ray examination showed that material lay in the distended loops —for an interminable time. This patient was made to realize the severity of secondary operation but expressed the positive conviction that she preferred death to her existing state, being at the time unable to correlate mentally. Indeed the mental symptoms were more serious than the physical. Operation revealed an immensely distended sigmoid and cecocolon, each communicating with the other through a stoma which readily admitted *four fingers*. The technical part of the previous operation had been perfectly performed, but the functional result was a failure. In order to restore normal conditions it was necessary to resect that portion of the sigmoid containing the stoma, to anastomose the sigmoid, to resect the terminal ileum and the colon as near to the splenic flexure as could be reached. An unusual amount of traverse colon had thus to be sacrificed because it was dilated as a result of the previous operation to the thinness of tissue paper and could hardly have been expected ever to regain proper tone. The ileum was then anastomosed to the extreme left transverse colon in the usual way. Result very satisfactory.

Appendicostomy is safe though insufficient in most cases. One important fact in its favor is that it places the stoma oral to the entire colon. This is in keeping with our observations, viz., that a stoma to be effective must be oral to the infected area.

Ileostomy.—This new procedure first intentionally employed in this country by us has limited and definite indications, but is of proven worth. It was devised and employed by an Italian some twenty years ago. In connection with our observations upon severe colonic infections we will deal with this procedure in a subsequent paper.

Plication of cecocolon may benefit, but it is questionable whether the results are permanent, and this coincides with our animal experimental work. The technical defect may be that the coaptation is peritoneal rather than muscular. We have now under consideration an adaptation of the autolytic pentagonal suture which we have long used experimentally. This introduces the problem of segmental resections, the most important work upon which has been done by W. Howard Barber.

Plication of the Bauhinian sphincter is said to be beneficial. We have had no experience with it; first, because our *x*-rays in the healthy humans show frequent leakage after enema, and, second, because we have shown experimentally that the mechanical action of all "valves" is of small value compared with the neuromuscular forces about them.

What of the cured developmental reconstruction cases in which the "valve" is excised?

Total colonic exclusion is a new operation, just described by Strauss. It will afford additional opportunities for study and may come to have a place in the operative therapeusis of the future, but its principles are quite at variance with the conclusions reached by us experimentally, and upon human beings twelve years ago.

Colectomy has a place but it is a small one because of the mortality and of the removal of omentum and the terminal colon which is active in elimination. Lardenois, however, demonstrated to us in Paris that it is possible to leave the omentum. Colectomy is indicated in diffuse polyposis, papillomatosis, diverticulitis, and in certain malignant tumors.

Of the many operations which have been suggested that of developmental reconstruction has proved very satisfactory in certain carefully selected cases. The writers have applied this term to

the ordinary operation of resection of the terminal ileum, the cecocolon, and the oral part of the transverse colon, because it exactly describes the procedure. The colon is reconstructed to the primitive or developmental type seen in the adult dog, or in the human fetus just following rotation, the great gut beginning in the right hypogastrium, there being no true cecum or ascending colon. We have felt that there may be a definite relationship between the symptomatic improvement in human beings after developmental reconstruction, and the fact that more primitive forms, like that of the dog, are free from colonic disease. We have called attention to the fact that this last formed portion of the colon is more liable to disease than the older aboral portion. As in the case of other organs which have become diseased and dangerous to the economy this organ, its function destroyed, should be removed.

One word in regard to colonic vaccines. There is this to be said in favor of the vaccine treatment: that it usually helps, it is free from danger, and if an operation becomes necessary subsequently it places the patient in the best possible condition to withstand it. It is valuable postoperatively.

Rectal feeding has long been a satisfying and comforting necromatic rite. It was ancient history when Hippocrates was a boy. Of all the delusions of grandeur ever inherited by the profession this was the most mythical. At last, however, we have arrived at something definite, viz., the use of amino acids. Urinary studies prove this. These final products of protein digestion occur in the blood, dialyze readily, and are the logical postoperative sustaining agent of the future.

One cannot consider the field of colonic surgical therapeusis without being convinced that the future holds out great things. And perhaps the greatest of these is the hope that physiological surgery collaborating with medicine may help us to find the true cause of the toxemia, and with it a cure which will not be operative.

THE DANGERS AND COMPLICATIONS OF TONSILLECTOMY.

By S. E. MOORE, M.D., LL.B.,

MINNEAPOLIS, MINN.

MEDICAL SCHOOL, UNIVERSITY OF MINNESOTA.

SPEAKING of pyelography, Clark says: "When a new method of diagnosis or treatment is suggested, there is immediately a wave of enthusiasm, which, in its intensity, temporarily overlooks the dangers and disadvantages incident to such a method. For a time these procedures are applied indiscriminately to all varieties of cases irrespective of indications, until the more conservative members of the profession strenuously object by presenting concrete examples of mishaps which have occured due to our inexperience and poor judgment. All new procedures seem to pass through this stage, and then finally settle down to their own proper level." These remarks can be appropriately applied to the theories of infective foci as causing so-called sequential constitutional diseases, and also to tonsillectomy as a therapeutic measure in the treatment of these systemic diseases, as well as in many local conditions of the nasopharynx.

The writer has recently observed a case, demonstrating the dangerous results of ill-advised removal of the tonsils. The medical literature of the last few years, during the period of the great popularity of tonsillectomy, is pregnant with untoward complications following this surgical procedure. This collection of cases, showing the risks and possibilities of the promiscuous use of this operation, is submitted to those who are interested in the subject.

The history of the case which concerned the writer is as follows:

In 1910 the patient suffered from an attack of polyneuritis, resulting from acute arsenical poisoning. A complete recovery was the ultimate outcome. In August, 1915, a mild recurrence of the neuritis reappeared in the posterior tibial regions of both legs. At that time he had an attack of acute coryza and bronchitis. Although by January, 1916, the condition was much improved, accepting the advice of physicians, he had the tonsils enucleated. The Slude-Ballenger tonsillotome was used and the operation was performed under local anæsthesia. The tonsils were successfully and completely removed, but the procedure was of a painful nature, due no doubt to the great pressure of the plate of the instrument pressing forcibly on the posterior pillars of the pharynx. One would presume that rupture of the fibers of the palato-pharyngeus muscles frequently accompanies the employment of this particular tonsillotome. Some non-toxic local anæsthetic injected into the posterior pillars would probably diminish the pain, when the Sluder-Ballenger guillotine is employed. Within four days after the operation the neuritis became widespread, involving nerves of the thighs, back, both forearms and arms, neck, feet, and chest. He was, of course, forced to go to bed, where he still remains seven months after the tonsillectomy. The patient had had one attack of tonsillitis in thirty years. The pathological report of the tonsillar specimens, made by competent bacteriologists and pathologists of the University Hospital, showed that a very small amount of tonsillar tissue really existed, and what was there displayed no areas of ulceration or suppuration. Streptococci were found in the culture taken from the tonsils, but this is nothing unusual, in fact, the rule. The amygdalae, therefore, showed no areas that could be interpreted as infective foci, from which so-called sequential disease could arise. The Wassermann reaction, taken twice, was negative. Indican was found in the urine.

In the experience of neurologists an individual, who has once been a victim of polyneuritis, regardless of the original cause, will be susceptible to a

recurrence at some future time from multifarious agencies. Sherwood[54] has written an interesting article on recurrent multiple neuritis. So far as the above case is concerned, regardless of the possibility of contributory factors, as intestional autointoxication, it cannot be reasonably denied, that the general invasion of the neuritis was the result of the tonsillectomy.

The amygdalectomy and infective-foci enthusiasts will no doubt suggest that the tonsils with incarcerated areas of infection, were the original cause of the neuritis, as following the operation, they will pertinaciously insist, bacteria and toxins are poured out from the tonsillar crypts and adjoining lymphatics, which being absorbed into the system, are carried to their destined tissues, thus justifying the theories of electives localization and specificity of streptococci, and thereby demonstrating beyond argument the law of cause and effect.

As above stated the tonsils pathologically showed nothing significant. The theory of the flooding of the body with tonsillar toxins, immediately after the excision *in toto* of those organs, is hardly compatible with the direction of the blood and lymph currents following the operative procedure. Hemorrhage and venous cozing continue for many hours, resulting in a thorough and complete autogenetic douching of the tonsillar fossæ, and it would appear to be a difficult and supernatural feat for intangible toxins without any *vis a tergo*, to combat with a blood current, which frequently becomes alarming in its intensity and occasionally results in death. Moreover the expert laryngologist in performing tonsillectomy enucleates the organ and its toxins *in toto*, at least partially encapsulated, a somewhat formidable condition and barrier to ambitious and hostile streptococcic toxins. In thyroidectomy and breast amputation, the situation is not parallel; toxins and cancer cells may be absorbed, for hemostasis is immediate, postoperative sloughing is rare, the operation is prolonged, manipulation is forcible in areas of freshly opened blood and lymph channels; cancer has no capsule, while in thyroidectomy occasionally the capsule is incised; and repeatedly portions of both structures remain to eliminate substances in a propituous and extensive field for absorption.

Posterior oral surgery is peculiarly handicapped, because of the inability to render the operative field sterile of the perennial presence of pathogenic bacteria, therefore sloughing occurs in practically all operative cases and often a severe local and an occasional general sepsis results. The throat is especially prone to gangrenous and other septic inflammations. Hence, what happier and more hospitable portal of entry for bacteria and their toxins could maintain a corporal existence than the sloughing postoperative throat bathing the freshly opened blood vessels and lymph channels, and accompanied by the sympathetic septic inflammation of the palate? By tonsillectomy a chronic tonsillitis or a normal state of that organ is converted into a condition of marked acuity of a week or longer duration in most cases. Instead of removing a focus, a source of infection is created. In many of these cases if only nature had been left alone she would have dealt with metabolic problems through a *vis medicatrix naturæ*.

Therefore, is it unreasonable to entertain the hypothesis that local reactions in joints, nerves, and other tissues, following tonsillectomy, result from a mild general bacteriemia or intoxication following absorption from the sloughing throat which invariably appears after amygdalectomy, the toxins in the blood stream attacking and irritating an already existing *locus minoris resistentiæ*? Such spot, regardless of its original cause, would respond to the irritation from the toxins absorbed from any source. For instance, if any individual with articular rheumatism, in his convalescence should be attacked by enteric fever, would not the joints, their resistance being lowered previously, or in fact still inflamed, probably manifest their invasion by the typhoid toxin through the clinical evidence of pain, swelling, etc.? A so-called typhoid rheumatism has been reported many times. Such a theory denies a specificity of tonsillar toxins for chronic rheumatic conditions. This hypothesis can run *pari passu* with the specific germ origin of *acute* rheumatic fever that the tonsil may be the portal of entry of the streptococcus rheumaticus or some other microorganism of that affection. For acute articular rheumatism, evidenced by rapidity of invasion and sthenic phenomena, suggests an infective bacterial etiology. But with chronic rheumatism, an indefinite term representing a disease involving multitudinous tissues, and furthermore characterized by various pathological changes even in the same structure, a specific bacterial etiological factor, seems, at least in the light of our present knowledge, not probable; otherwise a cure of the rheumatic condition, following tonsillectomy would be the rule, which is decidedly *not* the case.

Possible neurological reactions in some cases of the so-called sequential diseases will explain the renewed activity of these constitutional diseases after tonsillectomy. Habit spasm, a pure neurosis, is practically always made worse after amygdalectomy.[48] Furthermore, chorea, although possibly associated with rheumatic diseases, occuring in those with unbalanced nervous systems, is frequently exaggerated after tonsillectomy.[17 43 85] Fright in these cases does the same thing.

Perhaps general nerve shock, lowering the vitality of a chronically diseased area, as a joint, or of normal tissue, as a nerve, and thereby permitting a toxin already in the blood to act deleteriously thereon, where under normal conditions no harm would result, might explain some of these reactions. Intestinal autointoxication and syphilis might be such factors.

Therefore, it might be said, that the widespread general polyneuritic phenomenon following the tonsillectomy, in the above case, was possibly due to either shock alone, or shock increasing the susceptibility of nerve tissue to an already existing toxin in the blood, or some reaction in metabolism, or a bacterial toxin elaborated in the throat, perhaps from the sloughing postoperative areas, but certainly *not* from a tonsil free of infective foci.

The extravagant and odd claims of those who believe in the theories of the specificity and elective localization of streptococci still remain unconfirmed by reliable bacteriologists, and wise physicians had best wait until competent investigators verify these statements, before the profession in general adopts them. If the tonsil is proven an excretory organ, as the work of Henke,[50] Pybus,[55] and Blum[55] suggests, the partisan of the above theories, however attractive, might meet with a certain amount of embarrassment.

Toxins expressed from the tonsils through manipulation, and thereby producing reactions in

joints, etc., must be of infrequent occurrence, otherwise intestinal colic, acting on the wall of the bowel in cases of enteritis, or the application of Bier's hyperemia treatment with the use of the Esmarch roller, or massage of the prostrate gland, would repeatedly cause such constitutional upheavals.

Multifarious complications have followed tonsillectomy, a surgical procedure, which is looked upon by many physicians as nursery surgery in more senses than one, but which in truth, as Joseph H. Bryan, the laryngologist, says, "is always a major operation."

Hemorrhage.—Many cases of alarming primary and some cases of secondary hemorrhage have been reported. A number of fatalities, due to this cause, are recorded. The writer knows of a case of death at the University Hospital from hémorrhage following tonsillectomy. The patient had erythremia. A colleague of Dabney"s reports a fatal case in a young girl, who swallowed quietly the steady ooze from the tonsillar cavity till exsanguinated. Crockett[2] reports twelve fatal cases and many serious hemorrhages occurring within a year and a half in and around Boston. Sewell[3] found reports of nineteen deaths and fifty severe hemorrhages. Stucky[4] records a death after operation from hemorrhage and nine cases of secondary bleeding which required ligation and suturing of the pillars. Schuchardt[5] reports a case, in which the court found a verdict, that death was due to hemorrhage, strangulation, or shock. Roe[6] speaks of a case of fatal hemorrhage, six hours after operation, the patient probably being a hemophiliac, the mother having died of uterine hemorrhage. Brown[7] reports a case of severe hemorrhage following tonsillectomy for chronic rheumatism, the patient nearly dying, the bleeding being difficult to control on account of sclerosed arteries. Ballenger[8] records a number of cases of hemorrhage. Price[9] reports a case of fatal hemorrhage. Shurley[10] records a case of serious hemorrhage. He was threatened with a suit for damages. Chenery,[11] Beck,[12] and Iglauer[13] report cases of alarming hemorrhages. Thompson[14] records a case of serious hemorrhage in a child, who swallowed the blood. Still[15] speaks of a death from hemorrhage following removal of the tonsils. Williams[59] has had a case of fatal hemorrhage in a child six years of age following amygdalectomy. Dickie[55] reports nine cases of serious hemorrhage. Dutrow[56] records five severe hemorrhages. Hopkins[57] reports two cases of secondary hemorrhage following tonsillectomy, one occurring on the ninth day, after operation, and the other on the fifth, tenth and twelfth days. Burack[58] records three dangerous hemorrhages. Agnew[61] reports a case of recurrent hemorrhage which lasted for days after the tonsillectomy. Following an amygdalectomy upon himself, a medical friend of the writer's had to summon the operator to check a hemorrhage, which at least to the patient's mind had the earmarks of fatality connected with its continuance. In Blum's[35] series there were four deaths and thirty-five cases of hemorrhage.

Nervous and Muscular Diseases.—Following tonsillectomy the neurological complications reported are usually functional in nature, but not always. A case of amyotrophic lateral sclerosis in an apparently healthy patient, which manifested itself shortly after amygdalectomy performed for arthritis, was reported to the writer by a member of the neurological department of the University Hospital. Pfingst[15] writes of a case of hemiplegia lasting four months resulting from this operation; also of a patient who had repeated attacks of hysterical strangulation and spasmodic flexion of the thighs (Bergh). Dabney reports a case of spasmodic laryngitis following the removal of the tonsils. A case of hysterical mutism reported by Hall[16] was interesting. This patient, a boy, had been acting queerly ever since witnessing the bombardment of Hartlepool. This condition had been accentuated after viewing a gunpowder explosion to which his father had been exposed. His symptoms had been attributed to enlarged tonsils and adenoids, and tonsillectomy was advised. The question of the correct diagnosis was disputed by the mother, who remarked, without being asked, that "he did not snore, he did not breathe through the mouth, and he did not speak thickly." However, medical persistency mastered medical prudence and conservatism and it was decided to operate. When so informed the boy became very much terrified and remained so up to the date of the operation, from which latter period through the following six months he was absolutely mute, never uttering a sound. Sewell[3] reports two cases of tonsillectomy, where trachectomy was necessitated on account of prolonged glottic spasm with collapse and cyanosis. Also one of torticollis following this operation. Hedges of Plainfield, N. J., records two cases of torticollis. Chorea resulting from tonsillectomy has been reported. Layton[17] refers to three cases of chorea, which began after operations on the throat. Analyzing observations made in the children's medical department of the Massachusetts General Hospital, Young[45] says that definite conclusions cannot be drawn from few cases; the occurrence of chorea after tonsillectomy in twelve out of twenty-one cases strongly suggests that removal of the tonsils does not offer the protection against chorea, and the always present possibility of endocarditis, that many have heretofore believed. Blum[35] reports three cases of chorea following amygdalectomy. Under septic complications will be noted the case of facial paralysis recorded by Stucky following enucleation of the tonsils. Dunbar Roy[26] reports a case of partial paralysis of the soft palate following the removal of the tonsils and adenoids. The writer knows of a case of severe backache accompanied by great weakness, which lasted several months, after amygdalectomy had been performed. It was due probably to a neuritis or myositis. Another case, reported to the writer, is being treated in a sanatorium for some post-operative psychical condition resulting from the removal of the tonsils. Still[15] has known tonsillectomy in a child subject to habit spasm to markedly aggravate the condition, and in other children following amygdalectomy to fall into a state of morbid nervousness, from which they did not recover for many weeks. The writer knows of a case in a normally cheerful and buoyantly spirited woman, where a prolonged depressed state followed tonsillectomy.

Sepsis.—Sontag[18] reports a case in which death ensued from general infection on the seventh day. Dean[19] records three cases of sepsis; one patient died on the sixth day; the second recovered, but suffered from a septic phlebitis involving the internal jugular vein and extended along the cerebral sinuses to the orbital veins, accompanied by thrombosis of the latter vessels on the left side and perhaps of the left cavernous sinus. Such was his belief, as there was exophthalmos with panophthalmitis on the left side and optic neuritis on the right side. Levy[54] says

that pyemia and septicemia with exophthalmos may follow the removal of adenoids, the infection passing from the pharyngeal plexus to the facial and ophthalmic veins. The third patient of Dean's also recovered after an illness due to gangrene of the muscles of the neck. Ballenger[20] reports two severe cases of streptococcic infection, and Pierce[21] records a case of infection resulting in a permanent torticollis following tonsillectomy. Deane[22] reports two cases of severe sepsis following the same surgical procedure. Bourak[23] records a death from gangrene reported by Terkenle. Stucky[4] refers to three cases of cellulitis, one with facial paralysis of five weeks' duration. Sewell[3] reports two cases of paresis of the soft palate. Bauchacourt[24] records a case of edema of the glottis with death following removal of the tonsils. Koplik[25] divides septic cases following tonsillotomy or enucleation into three classes; first, a form running a fever for several weeks without endocarditis or other lesion; second, cases of pyrexia combined with endocarditis, which may have a fatal issue; third, a form of sepsis in which infection is severely hemolytic, and causes destructive blood changes with signs of sepsis, such as profuse hemorrhagic ecchymotic areas on the skin, severe hemorrhages from the bowel, and areas of bronchopneumonia. Koplik must have seen many cases of postoperative sepsis following amygdalectomy so to classify this condition. Ballenger[8] reports another case, of a physician, from whom he removed the tonsils, who had general septicemia, and took six months to recover. Freer[27] records two deaths from pyemia. Martin[26] reports two deaths from septicemia following this popular operation. Still[48] speaks of a death apparently due to sepsis following amygdalectomy. Dickie[53] reports a case of retropharyngeal swelling, and Vanderhoof[50] records an abscess under the angle of the jaw following tonsillectomies. Blum's[85] series showed a death from edema of the glottis.

Endocarditis.—H. L. Ulrich of Minneapolis told the writer of a case of acute ulcerative endocarditis which resulted from amygdalectomy. Koplik[25] has published reports of cases of heart disease following tonsil operations.

Diphtheria.—Wagner,[28] Caillé,[29] Levenstein,[30] and Kolbrak[31] report cases of diphtheria following immediately upon removal of the tonsil; the patient of the last-named physician died.

Bronchiectasis.—Lilienthal[69] records a case of bronchiectasis following tonsillectomy.

Pulmonary Abscess.—Wessler[82] reports eight cases of lung suppuration following tonsillectomy under general anesthesia. Richardson[33] records two cases of pulmonary infarct, one necessitating an opening to drain a lung abscess. Scudder[65] calls attention to lung abscesses following tonsillectomy. Beck[12] reports a case of pulmonary abscess following amygdalectomy. Manges[81] records nine cases of abscess of the lung after tonsillectomy.

Pulmonary Embolism.—LaPlay[32] reports a case of pulmonary embolism following amygdalectomy.

Hyperpyrexia.—Richardson[33] and Wishart[34] report fatal cases from hyperpyrexia. The latter's patient's temperature went as high as 107°.

Emphysema.—Richardson records a case of subcutaneous emphysema following amygdalectomy. Parrish[35] reports a case of emphysema on the face, neck, and chest after removal of the tonsils.

Pneumonia and Pleurisy.—Crockett[2] refers to patient of his own, who died from ether pneumonia, followed by empyema, acute mastoiditis, and meningitis. A number of other cases are reported, but it would be difficult to assign the tonsillectomy or ether as the real cause. Dickie[53] records a case of bronchopneumonia following amygdalectomy. Blum in his report says that tonsillectomy increases respiratory affections, instead of preventing them. Particularly severe lesions have supervened in the cases cited—as mastoid, ear trouble, and asthma.

Rheumatism.—A number of cases have been ascribed to tonsillectomy. What improvement in this condition follows the therapeutic removal of the tonsils for this affection has been assigned to the abolition of a specific etiological factor. Possibly this can be explained, as suggested above, by the removal of a general, not specific, irritating influence. Dickie[53] reports a case of acute articular rheumatism following tonsillectomy. Young[13] records two cases where immediate recrudescence occurred after amygdalectomy.

Status Lymphaticus.—Packard[38] reports a case of probable death from this cause, although an autopsy was performed to confirm the diagnosis. Harris[39] records a death from status lymphaticus following tonsillectomy. The necropsy revealed an enlarged thymus gland, which weighed eighteen grams. Dickie[53] reports the death of a child, age seven, probably from status lymphaticus.

Amygdalotomy Rash.—Dickie[53] reports scarlatiform rashes developing after tonsillectomy. Wingrave[37] records thirty-four such cases. Forsyth reports similar results. Richardson[33] explains this phenomena as due to the autointoxication from the blood, which is swallowed during the operation. Beck[12] records a similar case to the above.

Dryness of the Throat.—Winslow[40] reports this condition as following tonsillectomy. Richardson[49] has many cases who come to him in the hope of being relieved of the faucial dryness due to amygdalectomy. Blum[85] speaks of similar cases.

Appendicitis.—As time goes on, more cases of this complication of tonsillectomy are being reported. Still, Lockwood, Pavy, and Bramwell mentioned the not infrequent association of tonsillitis with appendicitis during the discussion of Lockwood's[41] paper, entitled "Acute Abdominal Inflammation in Children." Metcalfe[41] reported two cases of appendicitis following tonsillectomy. An inflamed appendix was removed on the fifth day after the amygdalectomy in one case, and a gangrenous appendix was operated upon on the eighth day subsequently to the tonsillectomy in the other case.

Local Results of Tonsillar Operations.—Stucky[42] reports various cases of adhesions of the pillars, impairment of the voice, difficult swallowing, and one case where there was matting down of the anterior and posterior pillars, causing traction around the fossa of Rosenmüller, resulting in a partial closure of the Eustachian tube with subsequent tinnitus. Roe[6] refers to two cases of impairment of the voice following attempts at tonsillectomy by other operators. Both cases had the tonsils left behind, but complete adhesions of the soft palate to the pharynx as result of the mutilation. Sewell[3] reports a case of retropharyngeal abscess following tonsillectomy. Bauchacourt[24] and Martin record three cases of edema of the glottis following amygdalectomy. Lederman[44] refers to a hematoma of the fauces after the same operation. Huber[45] reports a lateral pharyngeal abscess due to the same procedure. Many cases have been recorded of injuries to the pillars, accidental removal of the uvula, cicatrices in the palatine arch, impairment of

movement of the vela curtain, and adhesions of the pillars. Cases of tonsillectomy affecting the singing voice are reasonably frequent. Balfour[67] says that statistics from the New York public schools show that in 10 per cent. of children operated on there has been mutilation of the soft parts surrounding the tonsils. Thompson[53] reports several cases of injury to the soft palate and uvula in tonsillectomies. Laceration and cicatrization render the voice nasal; rapid formation of granulations requires weeks for removal' Pfingst[15] reports fifteen cases where the pillars were buttonholed during the operation. Delavan[16] has noticed severe inflammatory conditions of the throat and nose following tonsillectomy, when the operation was performed during acute inflammation of the throat and even during convalescence from grippe. Sheedy[47] found forty deformed throats out of fifty cases operated upon elsewhere; of these 5 per cent. complained of difficulty in using certain words, and had nasal intonation, and two had practically lost the singing voice. Wishart[52] reports three cases of irregularity in the palate arch resulting from contracture, and a bad effect on the singing voice in another case. Dickie[53] reports cases of scarring of the soft palate and fusion of the pillars. Stucky[4] refers to a case of limitation of tone production after the operation. Blum[55] notes injuries to the soft palate and uvula, impairment of speech, cicatricial bands causing discomfort, and contraction of the pillars. Roe[9] has devised plastic operations for the relief of postoperative conditions following tonsillectomy.

Infection of the Middle Ear.—Still[48] has found acute otitis media to follow tonsillectomy. Dickie[53] reports twelve cases of acute suppurative otitis media following amygdalectomy. One led to a fatal meningitis. Blum[55] reports similar cases.

Cervical Adenitis.—Dickie[53] reports a case of cervical adenitis following tonsillectomy. Cervical adenitis is not cured by amygdalectomy (Blum[55]).

Anesthetic Fatalities.—Sheedy[60] reports four deaths following the use of cocaine and adrenalin solutions in tonsillectomy. Still[48] speaks of two cases that died under the anesthetic, and Dickie[53] reports a case of death following amygdalectomy, the probable cause being delayed anesthetic poisoning.

Shock.—Still[48] speaks of another case, in which death appeared to be due simply to shock, and he further states, "I could quote other cases from my own experience in which life was all but lost through this operation."

Lucemia.—Ireland, Baetzer, and Ruhrah[56] report the case of a boy, who following an attack of tonsillitis had the tonsils removed. For a month or more following this, he complained of abdominal pain, diarrhea, and nosebleed. A diagnosis of lymphatic leucemia was made upon the evidence of an enlarged spleen and lymphatic glands, and the blood picture.

Enuresis.—Still[48] has known tonsillectomy to aggravate this condition. Swartz's[57] series shows no connection between adenoids and tonsils and enuresis, where the operation was performed for the relief of the incontinence.

Diabetes.—L. H. (U. of Minn. Hosp., 8754), female, admitted May 22, 1916, with the diagnosis of diabetes mellitus. The patient complained of polyuria and general weakness. Urine showed glycosuria (7 per cent.) and acetonuria on admission. On treatment the sugar quickly disappeared, she practically not manifesting any glucosuria up to the date of her tonsillectomy, which was performed, under local anesthesia, on June 28. The following day a large amount of sugar in the urine was reported, and, notwithstanding treatment, the sugar failed to diminish in quantity during the rest of her stay in the hospital, which she left on July 7. The patient blamed the tonsillectomy for her postoperative condition.

Miscellaneous Results.—Specialists reporting to Blum[55] speak of the following conditions as having followed tonsillectomy: tendency to become overfat, development of signs of hyperthyroidism, recurrence of adenopathy, nephritis, prolonged depression in adults, increased colds, epileptiform convulsions, failure of relief of secondary infection, and acidosis. As to the thyroid gland it is interesting to note that Theisen[95] reports six out of seven cases in young women of thyroiditis as occurring with or directly after an attack of tonsillitis. The glands in all cases were previously healthy and two developed permanent goiters subsequently.

The above cases have been reported by a *few* eminent specialists, who in the main are clever operators and men of sound judgment. If they record so many cases as complicating tonsillectomy, we can only conjecture how many hundred fatalities and sequelæ have followed the promiscuous employment of this surgical procedure by the general practitioner, the pseudospecialist, the quasispecialist, and specialist. Death and postoperative adhesions probably seal the mouths of their patients.

Canines are muzzled because of their potential power to transmit rabies; typhoid carriers are quarantined; chloroform, because of the fatalities following its use, has been discarded in many localities, and "Dämmerschlaf" following a very low fetal mortality ascribed to its employment has been prohibited by the board of directors in at least one hospital in the United States; but tonsillectomy, with its fatalities, dangers, and complications goes on unmolested.

Amygdalectomy[92] is not a recent addition to our surgical procedures. Writing in the year 10 A.D., Celsus says, "Tonsils which remain indurated after inflammation if covered by a thin membrane should be loosened by working the finger around, and then torn out, but when this is not practicable they should be seized with a hook and then excised with a scalpel." We are now reaping the whirlwind, the result of the momentum of ages, which was sown centuries ago by the immortal but radical Celsus.

Every intelligent physician recognizes the necessity of the removal of the tonsils and adenoids under certain legitimate and well-recognized conditions. Still,[48] whose views are always sound, recommends tonsillectomy under the following circumstances: (1) Recurrent earache, and still more the slightest degree of deafness. (2) General ill health; the child is pale or of pasty complexion, caused by defective aeration of the blood and insomnia due to hypertrophied tonsils and adenoids. (3) Hypertrophied tonsils with recurrent attacks of acute tonsillitis, which can be cured only by the removal of the tonsils. But a slight tendency to nasopharyingeal catarrh or an occasional attack of tonsillitis is not *per se* a sufficient justification for operative interference. (4) Catarrh starting in the nasopharynx spreads to the bronchi repeatedly, so that it may be necessary to remove adenoids. (5) Asthma and laryngitis stridulosa, only when there are other reasons for removing accompanied hypertrophied tonsils and adenoids. (6) Deformity of the chest resulting from throat obstruction. (7) In rheumatic affections, whether the removal of the tonsils can prevent this trouble has yet to be

determined. (8) Remove the tonsils in cervical adenitis in a child of a tubercular family or of a known tubercular tendency, but judgment is to be used in the tonsillar removal if these glands are inflamed or caseous, as irritation of the glands following the tonsillectomy might extinguish the last chance of the subsidence of the glandular inflammation. (9) *The mere presence of adenoids and tonsillar hypertrophy is not sufficient ground for operative interferenee.* (10) Tonsillectomy does good in certain cases of epilepsy.

Richardson,[49] speaking of the local indications for the removal of tonsils suggests operating upon hypertrophied tonsils, or those which are the seat of chronic lacunar infections, or of follicular tonsillitis or abscess formation, or tonsils which are painful on swallowing or tender on pressure. But he says[93] that "tonsillectomy may be at times attended by serious, even fatal, complications. With such knowledge, is it proper or wise to suggest this operation, as is so often done by the internist with insufficient and inaccurate data from a local standpoint as a prophylactic measure?" Further on he states, "I believe that a few general conditions probably have their portal of entry into the general system through the tonsil, but I would demand that, in every individual case, the tonsil be first proved to be guilty before it is sacrificed. One must hold steadfastly in mind the fact, when suggesting such a procedure under such conditions, that we by this operation are placing the patient in danger of his life, probably a greater danger to his life than the probable remote infection."

The fact that certain good results, temporary at least and perhaps permanent in some cases, have followed the removal of infective foci for the benefit of certain so-called chronic sequential systemic diseases is no reason why this procedure should be employed without reason or limitation. It is its promiscuous use that is deplorable. To remove a tonsil, in the light of our meager present knowledge, because no other cause can be found, is both unsound and unscientific. Wise physicians will not expect too much from the removal of infective foci. As a sovereign remedy for many chronic constitutional diseases, its Cheynes-Stokes respirations will soon be forthcoming, notwithstanding a certain limited number of apparently beneficial results, suggesting its reasonable and restricted applications.

Concerning the function of the tonsil, during the last two years, Henke[50] and Lemart have injected the nasal mucosa with solid particles in suspension, and have found a direct lymphatic communication exists between the nose and the tonsils. A similar communication exists between the mucous membrane covering the alveolus of the upper jaw and the tonsil. These lymph currents pass through the tonsils to its free surface and act as a powerful defensive mechanism. The function of the tonsil is comparable to an ordinary lymph-gland, and having a large free surface, they offer an exceptional opportunity for the excretion of foreign substances. It follows that tonsillitis alone or in association with rheumatism or endocarditis is the result of lymphatic infection, the portal of entry being in most cases the nose, the accessory sinuses, or the mucous membrane of the mouth (Fraser[1]). Schoenemann[51] regards the tonsil as submucous lymph glands, and acute tonsillitis as due to infection reaching the tonsils from the area which it drains; that is, the lower part of the nasal cavity. Pybus[52] says, like other lymph glands, the tonsil no doubt produces lymphocytes; that it receives lymph from the nasal cavities and acts as a filter in infections of this region; pigment granules injected into the nasal mucosa may be extruded on to the free surface of the gland. By a process of absorbing organisms and toxins, the tonsils may act as immunizing agents to the body as a whole (Pybus[55]). Blum[85] injected chemicals and bacteria into the cervical glands and recovered them in the tonsil and mouth. He, therefore, contends that the tonsils are excretory organs. Brieger, Goerke, and Stohr observed the emigration of lymphocytes from the center to the periphery of the tonsil, thus suggesting that the tonsils, as modified lymph glands, may combat infections.[55] Makuen[61] considers that the tonsil is beneficial to voice production, as it improves the resonance of the voice, and by keeping the pillars apart gives direction to their action in voice production. This seems a reasonable suggestion as so many singers' voices are injured by tonsillectomy. Ashurst, Wright, Swain, and Blum believe that the tonsils are eliminative organs for systemic diseases, including scarlet fever and diphtheria, Ashurst, for the waste products of dentition (Wright); and tubercle bacilli (Swain and Blum[85]). As dryness of the throat is a frequent complication of tonsillectomy, possibly the normal tonsil encourages the accumulation of saliva in that region. The suggestion that operative injury to the tonsillar branches of the glossopharyngeal nerve causes dryness and pain is not established (Shambaugh).

The operation of tonsillectomy has become unrestrained and apparently unlimited in its application. A physician in general practice, to the writer's knowledge, recently recommended within five minutes amygdalectomy to the first three patients, whom he had seen in his office that afternoon. Such röntgenological vision on the part of some physicians is really remarkable in view of the fact that the best laryngologists agree that the question of a diseased tonsil is often a difficult one to decide from mere inspection.[62]

The public has been unfortunately educated to have their tonsils removed. A vicious result of a promiscuous procedure. Nearly every laryngologist has patients who have diagnosed their own cases and come to the physician's office requesting a tonsillectomy. Forty boys within one month have had their adenoids and tonsils removed, and seventy-five more are scheduled for the same operation at a training school in Minnesota because the "medical fraternity finds that these organs are largely responsible for delinquency in the young." A specialist[63] at the Massachusetts General Hospital, discussing the results of tonsillectomy at that institution, writes as follows: "Of the fifteen cases in which the reason for removal is not known several were no doubt operated upon because they were under an anesthetic for adenoid operation and it was thought just as well to get the tonsils out, too, without considering *whether there were good reasons for their removal or not.*" This statement reminds the writer of the three indications for cesarean section at a large eastern maternity hospital; they are, pregnancy, the patient cannot speak English, and is anesthetized. Specialists' replies to Blum[85] questions, resulted in the following conclusions: Sixteen laryngologists performed tonsillar enucleation about 10,014 times; 7,486 before, and 2,528 after fourteen years of age. Among the indications for tonsillectomy given by these special-

ists were malnutrition, systemic poisoning, chronic hypermeia of fauces, endocarditis, nutritive disturbance, obscure stomach trouble, retarded development, anæmia, asthma, focus of infection, foul breath, anorexia, restless nights, and so-called bilious attacks. Only one specialist objected to the promiscuity with which tonsillectomy is performed. One operator showed a baby to Blum in whom he had removed healthy tonsils "because the baby being anesthetized for adenectomy, he thought he might as well remove the tonsils and so avoid future trouble." Another operator from 1906-1914 had performed 8,000 tonsillar enucleations, equivalent to nearly three operations per day in one man's practice.

Barnes[7] advocates tonsillectomy for the cure of quinsy during the acute attack, and Harrison[70] favors amygdalectomy during the acute stage of ulcerative endocarditis. These physicians apparently prefer individuality in surgical practice. Another laryngologist,[10] in discussing the selection of the period for tonsillectomy in emergency from danger of suffocation, in cases of diphtheria and certain septic conditions, suggests that amygdalectomy should be the rule and not the exception. He says that no harm can possibly be done by removing the local focus of infection and thoroughly swabbing the nasopharynx with iodine or peroxide. But why cause further local reaction and constitutional shock, when intubation and tracheotomy run on all fours with experience and common sense? Diphtheria being an acute septic process, thrombi already present, may become dislodged from the surrounding inflamed tissue through manipulation. Rare indeed would occasion arise when indications would suggest tonsillectomy in preference to intubation or tracheotomy in these cases. Perhaps where there existed a pharyngeal diphtheria and the swollen tonsils were actually obstructing respiration, tonsillectomy as a life-saving procedure would be indicated. The resulting hemorrhage would probably relieve the local congestion.

In 1912 in Philadelphia there were 37,000 recommendations to parents that their childrens' tonsils receive immediate attention. In response to letters to several specialists in New York written by the school department in trying to set some standard for operative interference, no two laryngologists agreed.[66] Sanger[76] is quite enthusiastic over tonsillectomy, saying that the tonsil operation in a case in which the removal is indicated is really a life-saving proposition.

The writer has recently investigated the annual reports for the last three years of various hospitals in the large cities of this country concerning the number of tonsillectomies performed at these institutions. The examination gave the following results. The reports of the out-patient departments are not included.

In 1912 there were 693 tonsillectomies performed in one hospital.

In 1913 there were 6,441 tonsillectomies performed in nine hospitals; the greatest number for this year was 3,152, and the smallest number 55, operated upon in one institution. The average number in each of the nine institutions for the year was about 715.

The total number for 1914 was 7,998 in fifteen hospitals. The maximum number in one hospital was 3,313, and the minimum number was 59 tonsillectomies. The average number for each of these fifteen hospitals was about 533 operations.

In 1915 there were 11,054 amygdalectomies performed in fourteen hospitals. The maximum number for this year in one institution was 4,750, the minimum number being 44 operations. The average number for each of the fourteen hospitals was about 789.

All of these institutions over the period of three years showed a remarkable increase in the number of tonsils removed except one hospital, a large Philadelphia institution, which reported a considerable decrease in the number of operations.

The writer would not attempt to give even an approximate number of amygdalectomies performed in this country based on the foregoing figures. These hospitals are all large institutions and their reports are only a suggestive index in regard to the total number of tonsillectomies performed throughout the United States.

Considering, however, the fact that there are over 7,000 hospitals in this country, to say nothing of hundreds of dispensaries, physicians' offices, and private homes where amygdalectomies are being performed; also from the consideration that probably at least one physician in every locality of a population of 1,000 and up is doing amygdalectomies, it is probably not an extravagant statement to make *that there are several hundred thousand tonsillectomies performed in the United States yearly, with the number greatly on the increase.*

Perhaps it may also be said, compatible with reason, that the usefulness of this surgical procedure, suggested by indications for its performance, based on our scientific knowledge of disease and the proven results of such surgical interference, has been greatly exaggerated and that therefore the justification of the majority of the above tonsillectomies has not and cannot be demonstrated. However, it is refreshing to note that among eminent authorities on this subject a decided and happy reaction has begun to see the light of day. Layton[37] of Guy's Hospital in a recent paper registers a plea for fewer tonsil and adenoid operations. He considers that they form a very important line of resistance to microorganisms, which invade the body through the nose and mouth. The hypertrophied tonsils may be the result of a surrounding inflammation. Therefore the original source of inflammation should be removed. Layton speaks of many cases of hypertrophied tonsils becoming of normal size after the teeth had been treated and nasal breathing exercises were taught (Pybus).[65] The late Eustace Smith drew attention to the mucous disease of the second dentition. Layton holds that this complaint resembles adenoids, *e.g.* cough and enlargement of lymphoid tissue, so by treating the dyspepsia, operation with its attendant risks of hemorrhage, choking, and death under an anesthetic may be avoided. *"The complete removal of the tonsils does not prevent further attacks of rheumatism"* (Layton).[37] Henke[50] claims that the frequency with which the tonsils form the portal of entry for many diseases has been much exaggerated. Still,[68] referring to relationship between tonsillectomy and rheumatism, says that "from clinical notes kept for some years of cases bearing on this point, the evidence only proves that the ordinary partial removal of the tonsils *does not prevent the recurrence of rheumatism* in a child who has previously had rheumatism." Richardson[69] states that numerous instances can be given of *acute and chronic rheumatism and rheumatoid arthritis where tonsillar enucleation has been followed by total failure to ob-*

tain relief. The writer knows of a young physician who was recently carried on a stretcher to the Hot Springs, Va., suffering from recurrent acute articular rheumatism. His tonsils had been removed several years ago. Comroe[68] and Richardson[49] agree that there appears to be a marked reaction in certain sections against the indiscriminate removal of tonsils. Comroe hopes that the tonsils will escape unnecessary and undeserved slaughter, and recalls the successful escape of a somewhat similar fate of the ovary, appendix, and the inferior turbinate. Richardson remarks that it has been stated that no adult should possess tonsils, nor even the site from which tonsils had ceased to exist." A prominent internist in Minneapolis has recently stated "that the tide has turned against the slaughter of the tonsils."

Young,[41] at the Massachusetts General Hospital, referring to the value of tonsillectomy in the rheumatic child as a preventive of recurrence of infection, says that his experience has been far from encouraging *since in more than half of the cases relapse has occurred.* Fredreich, Layton,[17] and Semon agree that the pendulum has now swung too far in the direction of operation, and that cases are often sent to them for tonsillectomy to cure all sorts of diseases. Balfour[67] of the Mayo clinic, in a very recent paper, remarks that it is still unsettled to what extent the tonsils should be held responsible for various forms of arthritis, lesions of the gastrointestinal tract, infections of the gall-bladder, tuberculosis, or exopthalmic goiter. Williams,[71] deploring the crippling effects in early childhood of rheumatism, suggests three important points in treatment: (*a*) rest, (*b*) "keep warm and dry," (*c*) good food. No mention is made by Williams of tonsillectomy. Richardson[49] objects to the frequent removal of tonsils which show no macroscopic evidence of disease, and the fact that the possessor of this type of tonsil may be the subject of an infection that cannot be accounted for, does not justify the removal of the tonsil. McKisack[74] does not consider that a convincing case has been made out for the view that a septic state of the mouth is a common cause of remote disease, although he admits that it is always a source of danger. He thinks that the extreme views which have prevailed on the subject are now becoming moderated. Blum[55] says that no single case of endocarditis has so far as he is aware been positively proved as emanating from the tonsil. McKenney[75] attacks the enthusiastic tonsilar operator. G. Hudson-Makuen[77] sounds a warning to the men who operate on the tonsil for the most vague reasons imaginable.

It is Hudson-Makuen's firm conviction that the tonsil rarely is the focus of severe general infection. He deprecates the wholesale manner in which patients are "tonsillectomized" in clinics as unsurgical in every sense. Blum[55] claims that "tonsillectomy" has become more than a therapeutic procedure; it has become a menace. He further states that there are too many patients operated on without positive indications and that this operation should not be performed in infants, and only rarely up till eight years of life. Laboratory theories are frequently silenced by the final verdict of clinical results.

What suggestions does the literature recording the experience of eminent operators offer in regard to the indications for tonsillectomy, and the methods to pursue to reduce as much as possible the unhappy results? Shurley says "that tonsillectomy in one case of pernicious anemia or acute leukemia is sufficient to impress the surgeon with the value of blood examinations in all suspected cases of anemia. One case of hemophilia is sufficient to establish the value of a routine examination to determine the coagulation point. One death from chloroform is a life-long lesson in the value of ether."

1. The remarkable number, regardless of its popularity, of fatalities and complications following tonsillectomy is astounding.

2. Thousands of unnecessary amydalectomies are being performed yearly. A great many are being done on meager theoretical conclusions, the latter not being borne out by fact.

3. Tonsillectomies, being major operations, should be done in hospitals and the operator should be a specialist, experienced in this work. Manges[51] says that three days in a hospital should be the shortest stay demanded of them.

4. Hospital internes should be instructed in the control of postoperative hemorrhage. The use of the compressor, cautery, artery forceps, ligature, suture of the pillars, and the employment of adrenalin and silver nitrate, should be explained to them.

5. Unless absolutely necessary, operations at the home, dispensary and the physician's office should be abandoned. Sepsis and hemorrhage is too frequent a complication.

6. All patients and parents should be informed that there are possible dangers and complications following removal of the tonsils.

7. Levy[54] says that in all cases the surgeon should make sure before operation that there has been no recent case of illness in the house.

8. Cocaine and adrenalin injections should not be made into the soft tissue surrounding the tonsils. Such a procedure is dangerous (Sheedy[60]).

9. Singers should be informed that tonsillectomy may injure the voice.

10. When possible, a pathological examination should be made of all tonsils removed. Many will probably be found to be normal.

11. Conclusions as to tonsillary hypertrophy should not be made immediately after an attack of acute tonsillitis. Inflammatory enlargement may subside several months later (Still[48]), and operative interference may be unnecessary (Layton[17]).

12. The tonsil should be viewed as normal and not guilty until proved abnormal and guilty. The standard of surgical interference should be the avoidance of operation when possible, instead of razeeing the tonsils out on the slightest pretext. Intelligent surgeons are now preserving tissue as much as possible, as the prepuce, ovaries, tubes, chronically inflamed appendices, gall-bladders, inferior turbinates, and in military surgery, the limbs.

13. The conservative laryngologist should always be the one to judge of the local condition of the tonsil. Physicians in general, unless they have been especially trained in nose and throat work, will not have had sufficient experience to pass on the pathology of the tonsil. The laryngologist would be wise, however, to consult an experienced internist, who has medical equipose, when the question of tonsillitis in reference to constitutional diseases presents itself for decision.

14. Still's[48] indications for tonsillectomy are sound. *Mere uncomplicated tonsillar hypertrophy does not call for operation.* Practically complete tonsillar involution takes place in the majority of children about the age of puberty.

15. Take a nose and throat culture in all cases before operation, as the patient may be a carrier, as diphtheria has occurred immediately following tonsillectomy, even in cases where only a throat culture was taken and found negative, the culture from the nose being neglected.

16. In all cases test the coagulation time of the blood. Perform no operation on any one when the clotting time registers beyond one minute and a half. Thrombokinase, as used at the Manhattan Eye and Ear Hospital, which acts on the fibrin ferment of the blood and forms a clot, is useful in controlling oozing. Also in these cases of delayed clotting time administer caloium lactate for several weeks prior to the operation and then test the clotting time of the blood. Use calcium lactate especially in cases of the lymphatic type. Wilson[72] has proved by the coagulometer that the blood-clotting time in adults can be reduced from seven minutes to one minute after the administration of 120 grains of calcium lactate. Fonio's[93] "separierende methode" determines which of the elements of the blood is lacking in the individual case. Fonio's "coagulen" (blood platelets) is a valuable hemostatic. Horse or rabbit serum can be tried. Hess[94] uses "tissue extract" as a hemostatic, applying it locally in cases of hemophilia. It has been used after tonsillectomy. The injection of human blood or serum, preferably familial, or diphtheria antitoxin, can be employed. Transfusion, by the multiple syringe method, may be used.

17. It appears to be a good plan to test the bleeding time of blood by the Duke's blotting-paper method. The bleeding point is independent of the coagulation time, so that it may be normal in a case of jaundice in which the coagulation time is very much delayed, or in a case of hemophilia. If the platelet count is diminished, then a delayed bleeding time indicates a hemorrhagic diathesis. Normally it is 1 to 3 minutes. It is delayed where the platelet count or the fibrinogen content of the blood, either occurring separately or at the same time, are excessively reduced. Constitutional purpura is characterized by prolonged bleeding time with normal coagulation time.

18. Ligate and stop all bleeding points after tonsillectomy, as in all other surgical procedures. Thompson's[14] test, keping the child on its side near the edge of the table, the foot of the latter being elevated, is a good one. Any bleeding comes out of the mouth and is discoverable.

19. Avoid shock by using ether in most cases. The effect of ether is exerted wholly through its action on the suprarenals.[91] Coagulation processes are hastened by ether anesthesia.[91]

20. The wisdom of the prophlactic removal of tonsils appears to be very questionable. *Results, thus far by competent observers, have not justified the indications in most cases.*

21. Operate on no patient with an elevated temperature, as the patient may be in the incubation stage of measles, scarlet fever, or diphtheria (Layton[17]). Richardson,[33] however, reports a subacute case, which after the patient had been running an elevated temperature for several months, the fever disappeared following a tonsillectomy.

22. Operate in no case where the constitutional or local condition is acute, as in arthritis, neuritis, coryza, tonsillitis, habit spasm (Still[45]), or when the patient is still convalescing from influenza. The reaction might be worse than the presence of the tonsils.

23. If avoidable, never operate in the winter months. Bronchitis is more apt to follow such a procedure (Still[45]). Layton[17] of Guy's Hospital performs no operations on the out-patients during the winter.

24. Perhaps it would be a good plan for laryngologists to take up the question again of the local treatment of chronic tonsillitis[77] and tonsillotomy. Pybus[85] says, where the symptoms are only mechanical, partial removal may suffice. Comroe[86] expresses the hope that many tonsils may be rescued from unnecessary and undeserved slaughter.

25. The snare or dissection method (Balfour[87]) probably surpasses any guillotine method. Finger dissection helps to avoid severe hemorrhage (Richardson[33]).

26. When the diphtheria bacillus, in carriers, is once lodged in the tonsillary recesses, causing repeated attacks of diphtheria, it is difficult to get rid of; the tonsils should then be enucleated (Pybus[85]). Malignancy is, of course, an indication for their removal.

27. The "follow-up" system of recording results should be instituted wherever possible.

28. More attention should be paid to oral asepsis, before and after tonsillectomy. Treat diseased gums and carious teeth prior to the operation. No abdominal surgeon would operate for chronic appendicitis with a furuncle in his line of incision.

29. Inquire into the history of jaundice, hemophilia, purpura, erythremia, the anemias, and diabetes before operating. Hemophilia is rarely dangerous after the twenty-fifth year.[89] As the skin and cellular tissue in diabetics are readily invaded by the microbes of suppuration, and as the multiplication of these microbes is singularly favored by the presence of sugar in the tissues (Bujvid), it would appear unwise to perform tonsillectomy upon a diabetic. Those suffering from diabetes stand all operative procedures badly.

30. Look for other foci besides the tonsils, and other etiological factors, and then try generally accepted treatment for the various chronic systemic diseases, before attacking the tonsils.

31. Tonsillar inflammation in those subject to occasional attacks of tonsillitis becomes more infrequent and may disappear altogether when middle age is reached.

32. Tonsillectomy for arteriosclerosis and heart disease, in the light of our present knowledge, is absolutely unjustifiable. Sclerosed arteries retract and contract with difficulty and severe hemorrhage is frequent in these cases and difficult to control.

33. Tincture of iodine (Marquis[54]) applied to the tonsillar fossæ after the operation, throat gargles, and compound tincture of benzoin, when used in the postoperative period, are useful applications to be made to help the disagreeable postoperative condition.

34. Perhaps the postoperative sloughing can account for some of the sequential systemic reactions in joints and other tissues. Systemic absorptions of toxins is the rule from acute septic areas.

We offer our argument against promiscuous tonsillectomy chiefly to the pliant intellect of youth, whose minds are not sclerosed, and who are not beyond the pale of regenerative thought. They are capable of molding their professional judgment upon a safe and sane basis, and we therefore present our appeal, regardless of the extreme ideas already inculcated in them, the product of what might be called bizarre teaching.

The tonsil has become the germ of medical hysteria, and by the indiscriminating and immoderate employment of tonsillectomy this operation has blossomed into the jester of therapeutic measures, and the clown of surgical procedures—but a prince of financiers nevertheless.

A number of case reports were obtained from articles by Dabney and Richardson.

THE SYPHILIS PROBLEM AMONG CONFINED CRIMINALS.

BY EUGENE N. BOUDREAU, M.D.,

AUBURN, N. Y.

ASSISTANT PRISON PHYSICIAN.

PREVIOUS to the introduction of the Wassermann test in the State Board of Health Laboratory, it was recognized, in treating inmates of our prison, that syphilis was very prevalent, but the exact proportion of them affected was unascertained. The urgent need of knowing the ones suffering of the malady was frequently felt, as when they were admitted to the hospital for treatment, or when we were asked to pass upon them before assignment to the kitchen; so as soon as possible we began sending the blood of those suspected, either by reason of their history or clinical picture, to the laboratory for diagnosis.

Between May 4 and December 1, 1915, one hundred and thirty-five specimens were sent, and of these sixty-nine showed I +* to 4 + reactions, or a percentage of 51.11 per cent. positive and 48.85 per cent. negative.

Since December I, 1915, all admissions have been subjected to the test unless they had been at Sing

* I+ cases are included as positive, because after provocative treatment the larger proportion returned positive.

Sing. During the five months following there were 279 admissions, of which 47, or 16.8 per cent., showed positive reactions. During the fiscal year of 1914-1915, 1,025 new inmates were received in the prison. The admissions increase each year, but even at the above rate we can expect at least 173 men (168 per cent.) admitted each year suffering from syphilis.

In addition, the test has been made on the whole population of the Women's Prison. One hundred and twenty-seven specimens were sent from there; of these, 84 were reported negative, and 43 positive, or 33.8 per cent. positive. The total population averages about 110. There are then about 38 of them in this prison at all times syphilitic. I will not include this number, however, in this discussion, but give these facts because of their possible interest. It seems to me that the above facts present a moral as well as economical duty for the State to perform. The moral side I do not wish to discuss, but the other I do.

Statistics show that a large proportion of those who have had the infective organisms of syphilis in their systems for a number of years without showing frank clinical symptoms, are potential paretics or tabetics. With this in mind, two tables were prepared which were intended to show concisely the physical findings in the 47 cases above mentioned showing positive Wassermanns, and also 50 selected indiscriminately that had negative Wassermanns. These tables were made up from the careful routine physical examinations made on admission by Dr. Frank L. Heacox, Prison Physician.

Of the first series, with positive Wassermann: 38, or 80.85 per cent, showed stigmata of degeneracy; 27, or 57.44 per cent., presented abnormalities of the alimentary system; 34, or 70.21 per cent., presented abnormalities of the respiratory system, including the nasal passages; 11, or 23.41 per cent., presented abnormalities of the circulatory system; 27, or 57.44 per cent., glandular enlargement, including 14 with epitrochlear glandular enlargement; 26, or 55.32 per cent., presented defective vision; 11, or 23.40 per cent., presented neurological symptoms, dizziness, headaches, convulsions, paralyses, etc.; 20 had chancres over 3 years ago; 11 had chancres less than 3 years ago; 31 admit chancre, but only 8 show scars; 16 deny chancre, but 3 show scars. Of the 50 showing negative Wassermanns: 39, or 78 per cent., presented abnormalities of the alimentary system; 47, or 94 per cent., presented abnormalities of the respiratory system; 47, or 94 per cent., presented abnormalities of the circulatory system; 28, or 56 per cent., presented glandular enlargement, including 6 with epitrochlear enlargement; 30, or 60 per cent., presented defective vision; 4, or 8 per cent., presented neurological symptoms; 7 gave histories of chancre.

Comparison of these groups, because of both the small number of cases and the little difference in the clinical findings, gives nothing that is conclusive, but it is rather suggestive that 23 per cent. show neurological symptoms in the first group and 8 per cent. in the second.

However, from the first group the following conclusions can be drawn: 36 per cent. would have been overlooked if histories alone were considered; 42 per cent. would have been overlooked if glandular enlargement alone were considered; 76 per cent. would have been overlooked if scars alone were considered; 57 per cent. would have been overlooked if all physical findings alone were considered.

Now, of all of these 47 cases none presented frank symptoms of tertiary involvement, and 20 have suffered from the disease for over three years. Then 20, or 7.5 per cent. of all admissions, we may say are potential paretics, tabetics, etc., or future wards of the State.

Granted that the State wishes to protect itself from this future expense, it should furnish, first, the necessary money for treating these cases; second, a workable method for treating so many cases for at least two years; and third, medical men expert enough to administer the treatment thoroughly.

Let me elaborate slightly on what these items mean. It is generally accepted that salvarsan or neosalvarsan is essential to proper treatment. At least five doses should be given. Salvarsan, when obtainable, costs $2.50 a dose. In conjunction with it, mercury should be administered intermittently until the cure is effected, but the expense of this is slight, comparatively, unless the bibromate is used as may be necessary in these cases. Finally, the iodide of potassium must also be given at intervals to make the mercury effective, and this is at present $6 a pound. It will require about one pound per patient a year. Summed up, then, the minimum cost per patient a year would be:

Salvarsan	$12.50
Mercury	7.50
Potassium iodide	6.00
	$26.00
And for 175 patients	$4,550.00

The expense the second year will be nearly doubled, for 175 new sufferers will be added each year.

It is easy to see that the problem of treating so many patients over a period of at least two years, many of whom, as shown by past experience, are delinquent if left to themselves, is a big one. At the rate of 175 a year there would be an average of 14 a month to be treated, necessitating the administration of 75 doses of salvarsan a month, to say nothing of the supervision of the iodide treatment and the injections of mercury. This is special work in a class with special treatments of the eye, ear, nose, and throat, or the work of the other specialties, and cannot be expected of the regular prison physicians.

Therefore, to fill the third requirement, a trained syphilologist should be furnished.

Summary.—1. 16.85 per cent. of the males and 33.85 per cent. of the females of Auburn Prison are found to have given a positive Wassermann.

2. 7.5 per cent. of all admissions are potential sufferers from paresis or tabes, or some other form of nervous syphilis, and, consequently, future wards of the State.

3. It would cost the State of New York approximately $9,000 a year to treat properly all the cases of syphilis at Auburn Prison.

4. History, glandular enlargement, and physical findings in general, are further proven to be lacking as evidence of the presence of syphilis.

5. Epitrochlear gland enlargement is not pathognomonic of syphilis.

Cutireaction in Gonorrhea.—Neisser spares no pains to obtain cultures of the gonococcus from urethral pus, but since in certain cases inconclusive results are obtained, he makes use of a vaccine from the doubtful culture for a scratch test, which he makes also on gonorrheal and nongonorrheal controls. Absence of reaction after forty-eight hours excludes gonorrhea.—*Berliner klinische Wochenschrift.*

LUPUS ERYTHEMATOSUS AND TUBERCULOSIS:

A SURVEY OF THE LITERATURE.

By LOUIS B. MOUNT, M.D.,

ALBANY, N. Y.

In the following résumé of the literature regarding the relationship of lupus erythematosus to tuberculosis, reference is made to the chronic form of the former disease only. It presents itself clinically as a patch of dull red color, with a somewhat raised border, dilated follicles, and tightly adherent scales. The usual and by far the commonest location of the affection is on the nose and the surrounding parts of the cheeks, presenting very often a butterfly form. Somewhere in the patch atrophy can be found.

Since the early work of Cazenave and Hebra distinguishing this disease as an entity, its clinical picture and histology have been carefully studied, and as a result many views have been propounded to explain its origin. Among these views the following might be mentioned: It has been looked upon as an angioneurosis; as a disease of the sebaceous glands; as due to a neoplasm; as an expression of tuberculosis, due either to the bacillus itself or to the toxin. Most of these hypotheses have been lost by the wayside, but one still is the topic of lively discussion, dividing dermatologists into two camps. This one view is the relationship of the disease in question to tuberculosis. It has its supporters and its opponents.

Jadassohn in his masterly monograph in Mracek's Handbook covered all the work done up to the year 1904, and as a result of the study of all the material arrived at the conclusion that there was no positive evidence of the tuberculous etiology of the disease.

Civatte in 1907 published an article in which he grouped the views of leading dermatologists into three divisions:

1. Those which held the disease to be of tuberculous origin. There were 17 members of this group, mostly of the French school, and they gave the following grounds for their belief: (*a*) There was a distinct family history of tuberculosis, or there was a tuberculosis present somewhere in the body; (*b*) Tuberculosis of the skin or tuberculides were present (*c*) Cases were seen in which a lupus vulgaris had become a lupus erythematosus; (*d*) The combination of glandular tuberculosis and lupus erythematosus was very common, and Darier narrated a case of lupus erythematosus which had its origin in the scar following extirpation of tuberculous glands; (*e*) Positive local tuberculin reactions were obtainable in some cases; and (*f*) It was possible to show histologically tuberculous tissue in patches of lupus erythematosus.

2. Those who held the contrary view. There were 25 members of this group and they claimed that (*a*) The occurrence of lupus erythematosus and tuberculosis in the same individual was not a common one, and that such a combination with so common a disease as tuberculosis could very well be a coincidence; (*b*) Some cases going to autopsy showed no focus of tuberculosis in the body; (*c*) In most cases a local reaction after tuberculin injection did not occur; (*d*) Animal inoculation experiments gave negative results; (*e*) The histological picture was not that of tuberculosis, and the therapeutic methods were not those of value in tuberculosis.

3. Those who took a middle standpoint, *i. e.* they felt that in some cases tuberculosis was present and that in others it was not. There were 7 in this group.

This work of Civatte's left the question no nearer a solution than did the critical review of Lewandowsky made in 1912. And yet in the literature of the last few years the casual relationship of lupus erythematosus with tuberculosis has become more frequent.

There are two main ways by which the relationship between the two diseases could be worked out: (1) Many cases of lupus erythematosus would have to be examined in order to find out whether they show any signs of tuberculosis clinically, by reaction, or by laboratory methods. (2) The attempt would have to be made to produce experimentally with the tubercle bacillus a dermatosis which would be identical both clinically and histologically with the disease in question. This method was attempted by Gougerot and Laroche in 1908. They introduced cultures of the tubercle bacillus into the skin of guinea-pigs. The result was an eruption which, the experimenters stated, looked clinically very much like lupus erythematosus and showed an almost identical histological picture.

The following reports of the relationship of lupus erythematosus to tuberculosis of the internal organs are of interest: Robbi in Jadassohn's clinic at Berne reported 87 cases of lupus erythematosus of which 51.6 per cent showed tuberculosis, the others giving no evidence of the disease. Ullman claimed that tuberculosis was demonstrable in from 80 to 90 per cent of his cases. Among Bernhardt's 27 cases only three were free from tuberculosis. Bunch, on the other hand, found the opsonic index to tubercle bacillus normal in seven of his ten cases. Only three showed tuberculosis of some internal organ.

Of greater frequency is the combination of lupus erythematosus and glandular tuberculosis, especially of the glands of the neck. The literature has numerous observations on this point. Of all of them Delbanco's case is perhaps the most important. The lupus erythematosus of his patient disappeared when a tuberculous neck gland was removed, and reappeared when another became affected.

Among other tuberculous affections with which lupus erythematosus can be associated, lupus vulgaris must be mentioned. The association is not met with often enough to point absolutely to a common causative factor, and yet is is not exactly uncommon enough not to arouse the suspicion that they may be related. In this connection Kyrle reported a very interesting case of two symmetrical patches on the face. These patches were diagnosed clinically as lupus erythematosus, but the microscope showed one of them to be lupus vulgaris and the other lupus erythematosus. Ehrman gave a description of a clinical lupus erythematosus which microscopically showed typical tubercle formation. The reverse condition has been described by Hoffman.

There have been many reports of the combination of lupus erythematosus with papulonecrotic tuberculide, also with erythema induratum of Bazin.

Much use has been made of the tuberculin reaction in the attempt to solve the problem. From figures already given it seems plausible that the general reaction would be obtained in the majority of cases. But this would be of no value unless the local reaction was also obtained. Relative to the

latter point Ravogli claims it to be fairly common. About a half a dozen workers have obtained a local reaction by rubbing tuberculin ointment and old tuberculin into the lesions.

Now and then a report has made its appearance in which lupus erythematosus was said to have been cured or improved by tuberculin injections. But since the majority have not been improved, no deduction of any value can be drawn from this.

Many have attempted to find the bacillus in the diseased area by examining stained sections and macerated tissue, by cultures, and by animal inoculation. There has been no success with the Ziehl method of staining sections, but eight positive bacillary findings have been reported, all of them obtained by the antiformin method.

Before taking up the last factor in relating the disease with tuberculosis, namely, animal inoculation, the main view of the opponents to the tuberculous etiology should be spoken of. They claim that the autopsy of individuals with lupus erythematosus does not always show the presence of a focus in the body. For this statement to be of value they must show that the lupus erythematosus area itself is not tuberculous, for it is possible that the infection might be exogenous and not endogenous. They also claim that the histological structure is not that of tuberculosis. Here again it is possible that a special soil might react atypically to the bacillus, or that there might be a special variety of the bacillus producing an atypical reaction.

Up to the time of the experiments of Bloch and Fuchs there were three positive animal inoculations with pieces of lupus erythematosus tissue. The first, a case of Gougerot, showed typical patches on the scalp. Guinea-pigs, inoculated with pieces of the tissue, were killed after five months and showed tuberculosis of the liver, spleen, and lungs; also of the glands nearest the site of inoculation. The second case, also one of Gougerot, produced in the guinea-pig tuberculosis of the liver, spleen, and lungs; also cheesy degenerated lymph glands in which bacilli were found. Gougerot was thus the first to show that Koch's bacillus could be the cause of a typical lupus erythematosus. The third reported case was that of Ehrman and Reines. Inoculation of a guinea-pig caused miliary tuberculosis of the lungs, liver, and spleen. This case also gave a general and local reaction after the injection of one milligram of tuberculin.

The greatest credit is due Bloch and Fuchs for their epoch-making experiments. According to their way of thinking there were exactly two methods by which the relationship of the two diseases in question could be determined, and these two methods were: (1) Obtain a corpuscular free extract of the diseased tissue, and by placing this extract into the skin of individuals who react to tuberculin produce changes of a specific nature, namely, epithelioid and giant cells, and also caseation. (2) Produce positive animal inoculations with pieces of the tissue.

To avoid all possibilities of error, the experimenters first examined in serial section all tissues used, and made use of such only as showed nothing histologically that might pass as tuberculosis of the skin.

In order to test out the first method they prepared an extract as follows: A piece of the tissue, including the subcutis, was excised, freed of the upper layers of the epidermis, cut up very finely, and rubbed up for several hours in a mortar with sterile quartz sand until a homogeneous mixture resulted. To this mixture eight to ten c.c. of sterile distilled water was added, and the whole shaken in a sterile bottle by means of a shake machine for twenty-four hours and then placed in an ice-chest over night. The next day the mixture was filtered through a Chamberland filter and the filtrate evaporated *in vacuo* at a temperature not over 30° C. to about 0.5 c.c. The result was either a clear or slightly opalescent yellowish liquid. With this extract they vaccinated cases of manifest tuberculosis, such as lupus vulgaris, tuberculides, lichen scrofulosorum, etc., using a control extract made from healthy skin of the same patient from whose skin the lupus erythematosus extract was made, and succeeded in every case in obtaining a reaction to both the Pirquet and the intradermal methods. The papules resulting from the intradermal method were examined histologically and showed the tubercle structure.

For their animal inoculation work they used pieces of lupus erythematosus tissue, placing them, under aseptic precautions, in the peritoneal cavities of guinea-pigs. Partial success also crowned these efforts, positive results being obtained in some of their inoculations. It was found necessary to carry the inoculations into the second and third series before positive findings would result. This might very easily explain the many failures in this direction, because in lupus erythematosus we may be dealing with a bacillus of such low virulence that its passage through a number of hosts might be required before enough virulence is attained to produce characteristic changes in the guinea-pig.

In conclusion, the work of Bloch and Fuchs might give grounds for their belief that lupus erythematosus of the chronic type may be due to an infection with the tubercle bacillus, perhaps of lowered virulence or of another variety, upon soil which in the majority of cases reacts in an atypical manner.

A NEW SYNDROME.

By SIEGFRIED BLOCK, A.M., M.D.
BROOKLYN, NEW YORK.

SINCE the study of ductless glands has become so universal many are the therapeutic claims advanced for their secretions, but few are the real virtues thus far elicited by the mere doctor. They are often heralded as the future medicines—the great panaceas for all illnesses, especially those, the cause or pathology of which is not definitely understood. It seems that the neurologist has had more dealing with these glandular extracts than most physicians because he sees so many cases which all kinds of specialists have designated as either incurable or undiagnosable. It is for this reason that the writer takes the liberty of suggesting an entity which may be regarded as new in that as a symptom-complex it is up to the present not described in the medical literature.

It must not be called "Old Maids' Disease" because the patients would not return for treatment so for the present at least, "Block's Syndrome" is good enough. Before the condition itself is described it must be remembered that many cases of so-called neurasthenia, hysteria, functional neuroses, headache, eyestrain, border-line psychoses, etc., must be included in this description. The report is founded on personal experience and corroborated by a good number of men in several of the specialties.

Definition.—A disease of women ranging in age from the full development of puberty to the menopause. Most of the cases occur between twenty-five and thirty-five years. Characterized by sleeplessness, a melancholic tendency, peculiar idea of personality, attacks of crying, general nervous irritability, sexual hypersensitivity, either loss or gain in weight, lassitude, and pigmentation of the skin.

Etiology.—This condition seems to occur mostly in temperate climate and its manifestations are the most marked in the transition seasons just after the hot summer or the cold winter. It seems that the morning is the worst time for these persons, although sleepless nights are very common.

The condition seems to be definitely associated with sexual development and the age of the sufferers varies just as does the height of sexual life in the human family. One thing is positive, that is that the center of sexual activity is the age at which the symptoms are the most pronounced. The vast majority of the cases the writer has seen were in unmarried girls between twenty-four and thirty-five years of age. Many cases of young widows, divorcées, or wives of men long away from home, as seamen, etc., have a similar series of symptoms.

It seems to be either a sexual disorder, causing an improper functioning of most of the ductless glands, especially those associated with the adrenal system; or, a disorder of these glands causing some sex aberration. The former seems more rational.

Pathology.—The only pathological changes thus far noted are *pigmentation.* This is brown in color and varies from an almost invisible to a deep, well-defined, deposit. It may occur in any part of the body, but is usually found on one or both sides of the face just back of the malar eminences. The next most frequent place for this deposit is on the forehead, more often lateral than central in location. This chloasma, as it is termed, is more marked during the menstrual epochs. It also stands out quite pronounced after great excitement.

There always seems to be some edema of the feet and ankles, but the urine is usually normal.

Symptoms.—Those patients claim to be tired, easily fatigued, and are always impatient and restless. They are very self-centered and easily insulted. They think that others are talking about them or scheming to take advantage of them in some way. This they resent and so make their presence in a family very undesirable. Statements are misconstrued and cause much worriment to the patients. Their inability to carry out a prolonged work completes a picture resembling that of neurasthenia with a mild case of Krapelin's paranoia combined with a few hysterical symptoms.

As in hysteria we can usually elicit some areas of either anesthesia or hypesthesia. At times we get hyperesthesia in some spots, but these do not occur very often. As in hysteria also the skin over the ovaries, mammæ, etc., is especially sensitive. There may be hyposensitivity of the palate.

As in neurasthenia we have the fatigue, the inability for prolonged work, insomnia, lassitude, etc.

Resembling paranoia we have continual doubt as to what is intended by certain statements, exaggerated ego. Self-conceit and the ego are not so marked as in the psychosis of Krapelin, but this is distinctly one of the most prominent symptoms. Memory for insignificant details, with the absence of thoughts about the important things of life, make the resemblance to this psychosis quite complete. The arguing, the desire to prove the point from weak premises, etc., make another parallel line of thought with the psychosis.

The patient worries greatly over her condition and tries various remedies for a cure. She is too stout and tries to get thin, or she is too thin and tries to get more flesh. She has her superfluous hair removed, her wrinkles taken out, her tonsils removed, her turbinates treated; she takes iron for her blood, she must go on a diet, etc. She becomes of a very jealous disposition, loses many of her friends, and her symptoms increase.

The reflexes are all exaggerated. Constipation is the rule, causing a coated tongue and a foul breath. Whether the last symptom has any connection is unknown. There is frequently too much urination, but this is simply one of the symptoms of the neurotic condition. Various habits, as scratching the skin on different parts of the body, or even mild forms of a tic as eye-blinking, or eating mannerisms may occur. Peculiar tastes as special desire for pickles, herring, etc., develop.

Sexually these persons seem to be hyperirritable. Actual consummation of the sexual act does not bring relief, except in a few cases temporary amelioration of some of the nervous symptoms may occur. These soon, however, reappear. Sexual perversion often is found in such cases. Those persons always wish for something which they cannot put in words, and the inability to get this something causes much sorrow. They are very susceptible to flattery, hence they become good material for all kinds of sharpers—financial, sexual, or otherwise. The quack doctor, the religious healer, and all sorts of faddists are met with open arms.

Treatment.—This disease is primarily a disorder of the internal secretory glandular system and the treatment must be divided into two distinct divisions; general and specific.

The general treatment which seeks to remove the cause of a few of the symptoms consists in a change of surroundings and a modification of the daily routine from which the patient obtains great but temporary advantage. Likewise change of diet is of value. Persons who before were meat eaters should live on a vegetarian diet while undergoing the treatment. Friends, especially so-called bosom-friends, should for a time be kept away. These persons are inclined to have a rather small circle of acquaintances and removal from these seems to work much good. Instead of the regulation three meals each day a smaller meal every few hours has its advantages.

A definite time fixed for rising and going to bed is of value. In fact our "clock-life" is well used here. By "clock-life" we mean a *definite* hour for everything, even for the toilet, using enemas if no other way will bring about the desired result.

Medication.—The specific medication in these cases is a combination of extracts of ductless glands. Just which glands are necessary depend upon the case. Extract of the whole ovary, together with some adrenal and thyroid extract, dosage varying with each case, makes a good general combination to start with.

It is a curious fact that although many of these glands act physiologically in opposing ways, when given in combination the results of the combination are positive instead of neutralizing, as one might expect. The cells of Leydig, from the ovary, work better in a few of the cases than the whole ovary. In one case, in the sister of a physician, nothing

except adrenal cortex, and thyroid extract gave any result. In another case only a fresh preparation, in capsules, showed results. Stock tablets were entirely without value in this case. Once a week we received fresh pituitary and ovarian extract, but added strychnine sulphate. Under this treatment a large chloasma disappeared, there was a gain of ten pounds in weight and the lady who had been regarded as an eccentric became normal. Among some of the changes noted were in one case that a woman who had been a man-hater changed and became a wife; her demeanor became quite feminine, although she had been formerly a very masculine type. Again a stenographer in a large insurance company who had been leading a life of immorality abandoned it for a decent one. The wife of a physician from another city who had a feeling of hatred toward her only little daughter was of a peculiarly neurotic disposition; her case had been diagnosed as dementia precox by several examiners. She has returned home now and is quite normal in her affections. This lady had two large pigmented areas on her right thigh.

In conclusion it may be said that by expert use of these glands many of our former impossible cases are relieved of a life of misery not only for themselves, but for all with whom they come in daily contact.

848 GREENE AVENUE.

ALBINISM, LEUCODERMA, VITILIGO.

BY JOHN E. LANE, M.D.,

NEW HAVEN, CONN.

THERE is little hope of securing relief from many of the extravagant absurdities of dermatological nomenclature and classification. Confusion of new and rare diseases, such as occurred with pityriasis rubra pilaris and lichen ruber acuminatus, is of course unavoidable, when such cases are described by individual observers in different countries; and we cannot expect to uproot from a language firmly implanted names, like anthrax, which have wholly different meanings in different languages. Perhaps, too, long names may be temporarily useful in describing new diseases. "Erythrodermie pityriasique en plaques disseminées," and the more recent "glossite losangique médiane de la face dorsale de la langue," are excellent examples of Brocq's admirable powers of description, but they fall haltingly from any other than a French tongue, and are a heavy load for any disease to carry indefinitely.

However, even if these are more or less necessary evils, it seems hardly necessary to perpetuate a lack of uniformity of names, applied to fairly well defined conditions, among dermatologists using the same language. This lack of uniformity exists to a considerable degree in the application of the terms albinism, leucoderma, and vitiligo, by English and American writers. In some cases the terms are also very loosely defined.

The purpose here is to illustrate the existing confusion, and to suggest, not a new terminology (quod di omen avertant!), but the adoption of the French one, which is definite and consistent. Definitions have been taken from some of the more recent books with no attempt at making a complete collection.

Albinism.—All dermatologists define albinism as a congenital affection, characterized by absence of cutaneous pigment. Most of them subdivide it into complete and partial albinism. Some limit the term to "the congenital conditions of achromia induced by *universal* absence of cutaneous pigment."[1] There seems to be no good reason for thus limiting it, and for departing from a usage which is generally accepted.

Leucoderma and Vitiligo.—Leucoderma and vitiligo are used as synonymous by most English and American writers. Here again there are some exceptions, for leucoderma is occasionally used "to designate the pigment-atrophy which is *partial* and congenital."[2] This also seems to be an added confusion and a departure from the generally accepted terminology. Vitiligo is also sometimes used exclusively to apply to the conditions for which most writers use both vitiligo and leucoderma.[3] If these two affections are to continue to be confounded, there is an advantage in discarding "leucoderma," as it is rarely used in this sense except in English, and is much rarer than vitiligo.

Leucoderma and vitiligo, when used as synonymous, are variously defined. "Vitiligo is an acquired pigmentary affection characterized by variously sized and shaped whitish patches with hyperpigmented borders."[4] "Leucoderma is a loss of pigment in the skin, probably due to some toxin."[5]

"The name leucoderma is given to affections of the skin characterized by the absence of pigment. This change in the skin may be primary or secondary, and it is to the *primary* form that the name leucoderma or vitiligo is given. It is *always* associated with increase of the pigment around the white spots . . . . There is a special variety affecting the neck of women suffering from syphilis."[6]

"An acquired disease of the skin, characterized by the appearance of white patches with convex outline extending at the periphery, surrounded *usually* by hyperpigmented skin.....All are agreed that there is no pigment in the epidermis of the leucodermic area, but there is a difference of opinion as to whether the pigment is increased in the surrounding skin or not. Increased it may be in some cases, but it *certainly is the exception* rather than the rule."[7]

German Usage.—By German writers albinism is used to mean either complete or partial congenital absence of pigment. Vitiligo is usually employed to represent the conditions for which both leucoderma and vitiligo are used by English writers, leucoderma being usually reserved for secondary achromic affections, and being rarely used without the addition of some qualifying word, as syphiliticum or psoriaticum.

French Usage.—In the French terminology albinism is used in the same sense as by German and the majority of English writers, signifying complete and partial congenital achromia. Leucoderma and vitiligo are not used as synonyms, and the two represent two different conditions, clearly distinguished from each other.

Leucoderma is an acquired achromia, characterized by a diminution or absence of pigment in the affected area, without any increase of the normal pigment in the surrounding skin.[8]

Vitiligo is an acquired achromia, or dyschromia, characterized by the development of one or more sharply limited spots of depigmentation surrounded by a more or less extensive hyperpigmented border.[9]

Neither the pigmentary syphilide nor the leuco-

melanoderma of Fournier is included; nor are any affections which show other than pigmentary changes. The simplicity and clearness of this grouping is apparent.

The confusion of the English terminology will be made more evident by placing some of the inconsistencies side by side.

Albinism is universal or partial congenital achromia.
is not partial congenital achromia.
Leucoderma is vitiligo.
is not vitiligo.
is partial congenital achromia (Albinism).
is not partial congenital achromia.
Leucoderma or Vitiligo (synonyms)
is acquired achromia.
is always associated with increase of pigment.
is usually associated with increase of pigment.
may be associated with increase of pigment, but this is certainly the exception, not the rule.
is made to include the pigmentary syphilide of the neck.
is loss of pigment in the skin, probably due to some toxin.

The differences in spelling may also be noted; leucoderma, leukoderma, leucodermia.

The simplicity of the French classification recommends it, and the clinical difference between leucoderma and vitiligo is sufficient to make distinctive names desirable. In addition to this there is accumulating evidence which seems to be tending to prove that vitiligo is a syphilitic manifestation. If this should prove to be the case, it will furnish a further reason for no longer confusing the two affections.

Milian asserts that "vitiligo is a purely syphilitic manifestation," and that though it is doubtful whether it can be cured by antisyphilitic treatment there is no doubt that it can be arrested by such treatment.[10]

Hudelo says that "the opinion that tends to attach certain cases of vitiligo to syphilis is becoming general."[11]

Joltrain found the Wassermann reaction positive in eleven out of eighteen cases of vitiligo. Two of the seven reactions which were negative were in old syphilitics, who had had the disease more than fifteen years before.[12]

Leucoderma is, of course, frequently a syphilitic manifestation, but it is also frequently due to other causes.

RESEARCHES IN TRICHINOSIS.

By WILLIAM LINTZ, M.D.,

BROOKLYN, NEW YORK.

PROFESSOR OF BACTERIOLOGY AND PARASITOLOGY, LONG ISLAND COLLEGE HOSPITAL; ASSOCIATE VISITING PHYSICIAN, BROOKLYN JEWISH HOSPITAL.

THE following experiments were undertaken particularly with the idea of ascertaining (1) whether the isolation of *Trichina spiralis* in the feces of patients suffering from trichinosis can be depended upon in the diagnosis of this disease, as preached in the textbooks, and whether the views of H. M. Hayberg,[1] J. Chatin,[2] and others who believe that the parasites discharged living in the feces constitute a factor in the spread of the disease is correct.

I am indebted to Dr. Edward Buxbaum for the autopsy material which came from a young woman. The muscle tissue employed in these experiments contained numerous living muscle trichinæ. This tissue was cut up in small pieces and fed to albino rats. The rats as a rule became very sick ten to twenty minutes after feeding; they would not move around, although they were very lively previous to feeding, their heads would droop, they refused nourishment, the breathing became very rapid, and they would begin to waste away. These symptoms lasted about four days, when the rats began to recover, and in two or three days appeared apparently normal.

The weight of the rats was between 100 and 150 grams. The amount of muscle tissue fed was between 4 and 8 grams. The method employed in searching for trichinæ was to make a saline emulsion of the fresh feces upon a slide and examine with the low and high powered lens of the microscope.

RAT I—Feb. 29, 1916. Fed with muscle tissue infected with trichinæ. March 2, 1916, again fed with the tissue. No trichinæ found in the feces. March 3, 1916. Made 56 spreads of feces, but was unable to find trichinæ. March 4, 5, and 6, 1916. Feces show no trichinæ. On the last day obtained the following blood count: Polymorphonuclears, 55 per cent.; eosinophiles, 1 per cent.; small lymphocytes, 40 per cent.; morphonuclears and transitionals, 4 per cent.; unidentified cells, 3 per cent. Red cells show metachromatophilia. Made daily examinations of feces, but found no trichinæ. We finally autopsied the rat on March 9, 1916.

Preparations were made of the skeletal muscles, diaphragm, heart, lungs, liver, spleen, kidneys, brain, and cord, but no trichinæ were found. No trichinæ were found in the stomach, but scrapings from the mucous membrane of the small intestine showed a moderate number of pregnant worms. Scrapings from various parts of the large intestine showed the presence of no trichinæ. There were also none in the fecal content of the large intestine.

RAT II.—Was fed on the very same days and with the same amounts of infected muscle tissue. Daily examinations for trichinæ were made from the feces, but none were found.

On March 7, 1916, the following blood count was obtained: White blood cells, 20,000; polymorphonuclears, 80 per cent.; small lymphocytes, 14 per cent.; large lymphocytes, 3 per cent.; eosinophiles, 3 per cent.; red blood cells, 9,100,000; hemoglobin, 95 per cent. Rat was autopsied March 9, 1916. The result of the autopsy was identical with that of rat No. 1.

RAT III.—Fed with infected muscle March 2, 1916. Daily examination of feces showed no trichinæ. Blood counts were made on the following dates:

	Mar. 6, 1916. Per cent.	Mar. 16, 1916 Per cent.	Mar. 18, 1916. Per cent.
Polymorphonuclears	69	55	57
Eosinophiles	2	1	1
Small lymphocytes	21	43	42
Large mononuclears	..	1	..
Transitionals	8	..	..
Normoblasts	..	5	19
Hemoglobin	90	..	100

Total white, 26,800; total reds, 7,990,000.

Rat autopsied March 20, 1916. Examined pieces of muscles of all four extremities, diaphragm, liver, spleen, lungs, heart, heart's blood, brain, cord, kidney, but found no trichinæ. No trichinæ in scrapings from gastro-mucosa or its contents. Found numerous adult pregnant trichinæ present in scrapings of mucosa of the entire small intestine. No trichinæ was found in scrapings from the large intestine or in the feces.

Rat IV.—Fed infected muscle March 2, 1916. Made daily examination of feces, but found no trichinæ. Blood examinations were made on the following dates:

	Mar. 16, 1916. Per cent.	Mar. 18, 1916. Per cent.	Mar. 24, 1916. Per cent.
Polymorphonuclears	55	50	55
Eosinophiles	8	4	4
Lymphocytes (small)	35	46	41
Mononuclears and transitionals	2	..	..
Total leucocytes	..	18,400	13,200
Total erythrocytes	..	8,960,000	8,300,000
Normoblasts	4	..	3
Hemoglobin	..	100	..

Autopsied rat March 28, 1916. Searched diligently for trichinæ in all organs and tissues, including scrapings from the gastro intestinal mucosa and its contents, but failed to find parasites *anywhere*.

Rat V.—Fed with infected muscle March 2. Made daily examination of feces, but found no trichinæ. Blood examination was made on March 16, showing the following: Polymorphonuclears, 76 per cent.; eosinophiles, 2 per cent.; lymphocytes (small), 21 per cent.; mononuclears and transitionals, 1 per cent.; total reds, 12,899,851; normoblasts, 10; hemoglobin, 100 per cent.; polychromatophilia present.

Conclusions.—At no time were trichinæ found in the feces of rats. Upon autopsy although trichinæ were found in the small intestine none were found in the large intestine or in the feces. Evidently the trichinæ undergo destruction in the fecal mass. Therefore, to judge by the experiment on rats, the finding of trichinæ in the feces is a myth and the feces play no rôle in the spread of this disease. One must not confuse the various parasites found in the feces which bear some resemblance morphologically to trichinæ spiralis.

In view of the fact that in the autopsy material mentioned above, numerous trichinæ were found in the muscle tissue while none were found in the liver, it would appear that F. Flury's explanation[3] (that the reason why trichinæ seek muscles is because they need glycogen) is insufficient, because if that were so one certainly would expect to find numerous trichinæ in the liver.

The cerebrospinal fluid in this case contained a moderate number of trichinæ.

Sepsis After Gonorrhea.—Pflanz reports a case of acute anterior gonorrhea of three weeks' duration, apparently cured by a silver salt. Prostatic massage and irrigation were followed by local abscesses and fatal sepsis. Bacillary finds negative.—*Medizinische Klinik.*

Medicolegal Notes.

Medical Books as Evidence.—In an action for personal injuries received in a railroad collision, the North Carolina Supreme Court makes the following rulings with regard to the use of medical works in evidence. The opinions of scientists as to producing cause of locomotor ataxia, recorded in their works and not introduced under oath, with no opportunity for cross-examination, are inadmissible in cross-examining a physician as to such disease. Medical works are not admissible in evidence, and, when not alluded to in direct examination cannot be got before the jury, over objection, on cross-examination, nor can this be done by indirection in assuming their supposed teachings. The opinion of an expert witness cannot be contradicted by showing on cross-examination what some author has said. When an expert has given an opinion and cited a treatise as his authority, the book cited may be offered in evidence by the adverse party, as impeaching testimony, but unless the book is referred to in cross-examination it cannot be used for this purpose. Questioning a physician on cross-examination who had testified as to cause of locomotor ataxia, by reference to stated opinions in medical books being inadmissible as substantive evidence, cannot be justified on the ground that it was to test the qualifications of the witness, where it was not so restricted at the time nor in the charge.—Tilgham v. Seaboard Air Line Ry. (N. Car.) 89 S. E. 71.

Reference to Medical Authorities Disallowed—Expert Evidence as to Hysteria.—In an action for damages for shock from a fallen electric light wire, the plaintiff, on cross-examination of the defendant's medical witnesses, elicited testimony that the plaintiff was not suffering from an organic disease or injury to the nerves or nerve centers, or any molecular change therein. It was held as evidence that witness knew it was claimed by some medical authorities that there might be a molecular change in the nerves from electricity, and that the contrary was also claimed, and that the question was undecided, thereby importing into the case the theory of some authority to refute the testimony of the defendant's witnesses, was reversible error.

It was also held admissible to ask a medical witness whether or not there was an element of deception and dissimulation mixed up with their ailments, either always or some of the time.—Sykes v. Village of Portland, Michigan Supreme Court, 159 N. W. 325.

Alcoholic Insanity as a Defense to Homicide.—The doctrine is almost universal that alcoholic insanity or mental incapacity produced by voluntary intoxication, existing only temporarily at the time of the commission of the homicide, is no excuse or defense in a prosecution therefor. Drunkeness is one thing, and the disease of the mind to which drunkenness leads is a different thing. Temporary insanity occasioned immediately by drunkenness does not destroy responsibility for crime, where the defendant, when sane and responsible, voluntarily makes himself drunk. To constitute insanity caused by intoxication a defense to an indictment or information for murder, it must be insanity caused by chronic alcoholism, and not a mere temporary mental condition.—Perryman v. State, Oklahoma Criminal Court of Appeals, 159 Pac. 937.

Revocation of License for Unprofessional Conduct.—The Washington Supreme Court, in proceedings to revoke a license to practice as an osteopath holds that the provision stating unprofessional conduct for which license may be revoked to embrace all advertising of medical business intended or having tendency to deceive the public or impose upon credulous or ignorant persons, and so be harmful or injurious to public morals or safety, is not unconstitutional, as so vague and uncertain as to leave the determination to arbitrary personal opinion of the medical board; nor is the provision as to advertising medicine to regulate or establish menses unconstitutional as vague and uncertain.—State Board v. Macy (Wash.) 159 Pac. 801.

Expert Opinion as to Ptomaine Poisoning.—In an action against café keepers for serving tainted food it was held competent for a physician of long experience in general practice, in reply to a question sufficiently hypothesizing the plaintiff's evidence to give his opinion that ptomaine poisoning may be caused by eating impure food or tainted meats, that the eating of tainted chicken may cause such poisoning to a human being, and that such taint in meat may be detected by its odor or by the microscope.—Glenwood Café v. Lovingood, Alabama Supreme Court, 72 So. 354.

POLIOMYELITIS AFTER-CARE.

THE aftermath of the poliomyelitis epidemic is replete with important medical and social problems which the community, as well as the medical profession, are resolved to meet squarely. Of the total of over nine thousand cases reported in New York City about one-fourth died, a considerable percentage escaped with light or no consequences, and about five thousand have come out crippled. Very many of the children have suffered paralysis of the lower limbs and approximately 75 per cent. of these come from families who must depend upon charitable medical relief. The factors of age, economic condition, and inability to walk created the immediate problem of transportation of patients to dispensaries for treatment. This had become a matter of first importance and two organizations had made it their business to attend to it, when recently the city has taken over the burden. All the other phases of the problem remain to be dealt with by private agencies.

The most important agency in the field is the New York Committee on After-Care of Infantile Paralysis Cases, which came into existence in August at the instance of the Health Commissioner of the city and with the financial support of the Rockefeller Foundation. The committee set itself to work immediately, but because of the newness of the problem and its perplexity and for various other reasons it started with work along the periphery. It devised a large number of forms for the tabulation of statistical information which will, no doubt, prove of real value provided medical treatment given by the dispensaries of the city, which forms the basis of the statistics, is up to a certain standard of efficiency.

The main problem, therefore, is the problem of organizing the medical and dispensary forces in such a way as to bring the largest results with a minimum of waste. The After-Care Committee should take it upon itself to see that the opportunities of the dispensaries which undertake after-care work should be of the highest possible order and all the assistance needed for the equipment and the necessary corps of workers should be forthcoming. The necessary funds should be raised by the Committee and divided among the individual institutions on the basis of quality and quantity of work. A careful system of supervision should be instituted and provision should be made for the home treatment of cases which, because of their condition, cannot be properly designated as ambulatory cases. It is, moreover, difficult to expect that mothers who have more than one child and upon whom devolve all the home duties would be able to give a few hours several times a week to taking the afflicted child to a dispensary for treatment and to keep this up for years. Means should be provided for taking care of children whose home conditions are such as to make it impossible for them to be seen in a clinic as often as is necessary. Visiting masseurs and nurses may, in a large measure, meet the situation.

The After-Care Committee has many hard and complicated problems before it and it is to be hoped that, with the cooperation of the profession and the hospitals and dispensaries which should be given unstintingly, it will be able to solve these problems to the best interests of the afflicted children and of the community.

NASCENT OXYGEN IN THE TREATMENT OF INFECTED WOUNDS.

WITH regard to the treatment of infected wounds, and practically all wounds of war are infected to a lesser or greater extent, there is among those who have studied the question at first hand a somewhat remarkably wide divergence of views. Some surgeons, whose reputations are deservedly high, hold that antiseptics are of little or no use to check the progress of sepsis, while others whose opinions are entitled to equal consideration contend that every infected wound should be treated antiseptically. Again, there is no unanimity of opinion as to the kind of antiseptic to be employed, although as the result of clinical experience, one or two chemical products appear to stand out. However, the comparative merits of the various antiseptics in use on the battle fronts and in the military hospitals can hardly be brought within the limits of an editorial article and besides they have already been adequately dealt with previously in these pages. The object here is to call attention to one means of checking the infection of wounds which has been somewhat largely used and very well spoken of by many European army surgeons. Of course, oxygenation, the method to which reference is made, is by no means a new procedure, but it has been brought into special prominence during the war.

The forms of wound infection over which oxygenation exerts the greatest effect are those of the anaerobic type, a type which has been especially prevalent during the war, owing to the conditions of warfare and to the nature of the soil in that part of France in which much of the fighting has been going on. The land of the north of France and of Flanders is intensively cultivated and therefore thickly manured, and in consequence the anaerobic spores teem in the soil, and it may be said that there are few wounds incurred in the locality which are not more or less infected by them. The object, then, of effective treatment is to get rid of these spores or to prevent them from multiplying.

Burghard, Leishman, Moynihan and Wright, in a memorandum published in the *Lancet* last spring, stated that the rational line of treatment of infected wounds consists in checking at the earliest possible moment the anaerobic infection of the discharges. The wound should be freely opened up and then carefully cleansed with an antiseptic solution, all foreign bodies, sloughs, and blood clots being carefully removed. Kenneth Goadby in the *Practitioner* for May, 1916, points out that free oxygen prevents the development of the anaerobic germ. Mr. A. G. Foulerton recommends the method of continuous oxygenation in the treatment of anaerobic infections. The cavity of the wound or some part of the wound must become free from oxygen before the spores can become bacilli and before the bacilli can vegetate. The wounded tissues must be deprived of oxygenated blood before their invasion by the bacilli is possible.

French and German surgeons concur with British surgeons in their views as to the effectiveness of oxygenation in preventing the spread of anaerobic infection. Indeed the fact is too well known to need emphasis, and the question has been rather how best to apply the method. It can be applied in two or three ways, but the easiest and in the opinion of many authorities an effective mode of application is by means of frequent or, if possible, continuous irrigation of the recesses of the wound with a solution of hydrogen peroxide. Moreover, such a solution is said to possess the further advantage of breaking up blood clots and generally facilitating the disinfection and cleansing of the wound.

While oxygenation is especially indicated in the treatment of anaerobic infection, it goes without saying that it is of value in all wound infections. Its main value possibly rests in its preventive properties, that is to say that anaerobic wound infection will be checked by the early employment of oxygenation and on the good old principle that "a stitch in time saves nine" whenever the form of infection is suspected it will be as well, if feasible, to employ the method. These, at any rate, appear to be the views of many surgeons of the Allied forces on the western war front and of the French surgeons in particular, who from the first have made wide use of oxygenation in the treatment of infected wounds.

RE-EDUCATION OF CRIPPLED SOLDIERS.

ONE of the most difficult problems presented by the European war is how to render the numerous maimed and crippled soldiers more or less independent and self-supporting members of the community. From all points of view a solution or as good a partial solution as possible of the problem is not only desirable but essential. The methods of warfare now in use have crippled, are crippling, and will cripple a very large body of men, and of men too who physically and mentally are of the best. It is necessary for their own well-being and for the well-being of the nation to which they belong, as also for the preservation of their own self-respect, that every effort should be made to re-educate these men in order that they may be enabled to earn their living by honest work.

France, as in so many spheres of human endeavor, is leading the way in the vocational re-education of disabled soldiers. Dr. Bourillon in the *Revue Philanthropique* of some months ago discussed this question at some length. He pointed out a phase of this matter which is apt to be overlooked—that it is not only the grave mutilations, such as the loss of limbs, which disable the soldier, but other injuries which, while not so arresting, are equally serious in their results. Such are paralysis, joint stiffness, the severing of tendons and nerves, all of which exert an important influence on the well-being of the individual in his relation to society. For instance, a man who has been a bookkeeper and who loses a leg in the war can earn his daily bread in the line that he followed formerly. On the other hand, a professional piano-player or a typewriter who has lost even a single finger will be handicapped so far as carrying on the vocation in which he had become an expert is concerned. Thus the situation must be considered from the point of view of the future of the invalided; it is the relation between his disability and his occupation which is the essential factor.

First of all, the disabled soldier must be aroused from the condition of moral inertia which is so frequently the outcome of the disablement. And this object can be well accomplished only by teaching him how to use to the best advantage, the physical qualities and mental abilities which have been left to him. If these cripples are allowed to lapse into a state of mental lethargy, it goes without saying that the ultimate consequences will be appalling. Work is the sole means by which they can be saved from this pit. But in order to be able to work so as to be of economic service to the State and to preserve the independence of their families and themselves, the large majority of disabled soldiers must undergo a course of re-education. They must not, however, be practically thrust into the workshop. They must be carefully examined so as to be sure that their physical condition is such as to allow of their following the proposed trade. Mind and body must first be subjected to functional readaptation.

A great deal of this repairing work can be done by the surgeon and the orthopedist. From the medical point of view, physiotherapy by massage, medical gymnastics, mechanotherapy, baths, douches, etc., go to cure or ameliorate paralysis, ankylosis, muscular atrophy, or other injuries caused by or following wounds received in war. Functional readaptation is of the highest importance from the moral and economic standpoint. From the moral aspect, it is of the greatest moment that the crippled soldier shall be self-supporting and self-respecting. If he does not work he will be something of a menace, for the idle man is dangerous to the nation, to himself, and to his family. From the economic aspect the idle crippled soldier will be a burden in place of a source of prosperity to the State.

PRODROMAL SYMPTOMS OF CEREBRAL HEMORRHAGE.

THIS subject is of perennial interest because some of the leading internists and neurologists assert that there are no prodromes and produce statistical material to sustain the claim. The great number of alleged prodromes tends to confuse the subject and proceeds as a rule from men of limited experience. Some clinicians believe in the Raymond type of apoplexy which is characterized by paresthesia in one hand but such cases are to say the least extremely rare. The neurologist lays the chief if not the sole emphasis on the presence of an increase in intracerebral tension due to a hypertrophic heart, but the latter cannot produce hemorrhage in the absence of certain vascular changes. Retinal hemorrhages occasionally serve as a true prodrome. Apoplexy in the obese is nearly offset by apoplexy in medium and thin subjects. It has been stated over and over by pathologists that there can be no typical apoplexy in the absence of certain miliary nodular swellings in the smaller arteries, and that these are practically congenital. The longer a man lives the greater the liability of these to rupture. The sudden increase in tension which causes the hemorrhage cannot be explained. Other stable factors, as hypertrophy of the heart, are doubtless present, and the determining causes show great variation and are often emotional.

In an article by Kisch cited in *Il Policlinico* September 17, the author enumerates as prodromes of apoplexy, permanent marked elevation of blood pressure with enlarged heart, beginning changes (sclerosis) in the vessels—notably in the brain and kidneys—and finally certain associated intestinal disturbances. In the plethoric form of acquired obesity the gain in weight is closely followed by a rise in blood pressure. The tendency of the fat is to accumulate in the abdomen—mesentery, omentum, the perirenal region, etc., with resulting disturbance of the abdominal circulation. If the subjects have indulged freely in tobacco and alcohol the vessels suffer more in proportion. The enlarged heart results from increase of blood pressure. Prodromes of apoplexy must therefore be sought in the loss of arterial elasticity, contractility, and permeability. The author here enumerates the evidences of cerebral arteriosclerosis as they are described in standard works of reference. Albuminuria is also a valuable prodromic indication, along with evidences of sclerotic kidney.

The intestinal disorders which the author has already termed of prognostic value are of the most varied kind, and are believed to be due to changes in the abdominal circulation. Of determining causes are mentioned excessive physical effort, running, mountain climbing, over-distention of the stomach, excesses in beer, sexual excesses, straining at stool, violent emotions (pleasurable or painful), weather variations, etc. Immediate prodromes are headache, vertigo, vomiting.

Kisch's views have no bearing on forms of apoplexy in the thin subject, the senile subject, and certain other types. He has done no more than call attention to the fact that men with cardiorenal disease, arteriosclerosis, and obesity often owe their deaths to cerebral hemorrhage. Evidences of these diseases are not to be construed as prodromes in the correct sense of the term. Apoplexy of this type is rather to be regarded as a complication or sequel of cardiovascular disease, or as a mode of death.

RHACHIALBUMINIMETRY.

THE present war has greatly increased the research of the spinal canal for albumin—in cases of cerebrospinal commotion, trephining, suspected syphilis, and metasyphilis, etc. Some advocate lumbar puncture in every case of commotion. Sicard and Cantalouse, writing in *La Presse Médicale*, are in favor of precipitation of the albumin with heat and trichloracetic acid (1:2). A special graduated tube, known as the rhachialbuminimeter, is used, and from 8 to 10 c.c. of cerebrospinal fluid is withdrawn for a test. Four c.c. of fluid is turned into the tube (it should be taken from the top) and the latter should be heated to 80° or 90° C. Then 12 drops of acid are added, the mixture allowed to cool off, and the tube is occluded with a rubber stopper. It must now stand perfectly vertical for five hours, when a reading is taken. (If there is no haste, it may be allowed to stand 24 hours, when the precipitate will have settled to a straight line.) Normal standards must, of course, be known. The precipitate may be followed up in cerebrospinal syphilis, tabes, and general paralysis, in order to mark the evolution of the disease. An increased amount of albumin, as shown by the tube, is a hyperalbuminosis which is prominent, for example, in cerebral syphilis. After 24 hours' standing, an albuminosis is quickly seen to be pathological, or the reverse. A residual albuminosis is perceived in hemiplegic cases after the subsidence of symptoms, and may be due to a persistent lymphocytosis. The authors term this the equivalent of a scar in solid tissue. As the height of a precipitate in a tube is only a rough measure of the amount of albumin present, the authors, by control solutions, in which albumin is weighed, are able to calculate values which have the force of actual weight.

PITUITARY EXTRACT IN POST-ABORTION CURETTAGE.

THIS use of pituitary extract, as suggested by H. D. Furniss (*Surgery, Gynecology, and Obstetrics*, September, 1916), seems such a logical procedure that one wonders at not having seen the suggestion made in print long before this. Furniss administers one cubic centimeter of pituitary extract hypodermically before curetting for incomplete abortion, and has found that the most favorable time to give the pituitrin is 15 minutes before the actual curettage is begun. When the interval between injection and operation has been less, the resulting contraction has not been so pronounced. Among the advantages which accrue from the preliminary injection of pituitary extract are that it produces firm contraction of the uterus, so that the curetting is almost bloodless, and much more easily done; and that because of the contraction the uterine cavity is small and the contracted walls present a resistance to the curette which makes their cleansing less difficult, and also lessens the risk of uterine perforation. Furniss states that as yet he has not had any excessive postoperative bleeding following the use of pituitrin; but, realizing that such a possibility exists, he advises packing uterus and vagina with iodoform gauze, which is to be removed at the

end of 24 hours. While Furniss' article refers to the use of pituitrin only before curetting for incomplete abortion, there seems to be no good reason why it could not be used to advantage under certain other conditions; for example, when curetting forms part of the operative treatment in those types of cases in which the uterus is relatively large and flabby, or when curetting is done in the case of an individual whose menstrual flow is habitually excessive. It would seem, therefore, that Furniss has called attention to a therapeutic resource that will ultimately be found valuable in a far more extended field in gynecological surgery than that covered by the original suggestion.

News of the Week

Civil Service Examinations.—The United States Civil Service Commission announces open competitive examinations to be held in various places on December 13, 1916, for the purpose of filling vacancies in the following positions:

Physician, male, in the Indian and Panama Canal Services, at salaries in the former from $1000 to $1200 a year, and in the later, $1800 a year. Applicants must be graduates of or senior students in recognized medical schools, between the ages of twenty-one and forty, and citizens of the United States.

Dental interne, male; a vacancy now exists in Saint Elizabeth's Hospital, Washington, at a salary of $600 a year and maintenance. In addition to the clinical work, the interne is given an opportunity for study and for experimental and research work in the pathological, histological and other laboratories of the institution. Applicants must be graduates of or senior students in regularly incorporated dental colleges, twenty years of age or over, unmarried, and citizens of the United States.

Further particulars and application blanks may be obtained from the United States Civil Service Commission, Washington, D. C., or from local secretaries of United States Civil Service Boards.

Opportunity for Pathologist.—The New York Municipal Civil Service Commission will shortly hold an examination for the purpose of filling a vacancy in the position of pathologist in the Kings County Hospital, Brooklyn, at a salary of $1,500 per annum. The examination will be open to citizens of the United States who are graduates of a reputable medical school. Applications will be received up to December 5, at the offices of the Municipal Civil Service Commission, Room 1400, Municipal Building, New York.

Diet Experiments.—Twelve employees of the Chicago Department of Health began on November 22 a two weeks' experiment intended to demonstrate that a person can be suitably and sufficiently fed on an expenditure of forty cents a day. Throughout the two weeks the diet squad will pursue their ordinary occupations and will endeavor to keep conditions as nearly normal as possible.

Sydenham Hospital.—The annual report of Sydenham Hospital for the year ending October 1 shows that during that time 2057 cases were treated in the hospital and 32,971 in the dispensary, of these 14,186 received free treatment. The deficit for the year was only $6,680.64, the lowest annual deficit since the organization of the hospital fourteen years ago.

Hospital Ships Sunk.—The White Star liner *Britannic*, the largest British ship afloat, which has been in use as a hospital ship, was sunk by a submarine torpedo or a mine, in the Aegean Sea on November 21. There were no wounded aboard at the time, and the loss of life was small. The British hospital ship *Braemar Castle*, bound from Salonica to Malta with wounded, also was sunk in the Ægean on November 23; it is not known whether the ship was torpedoed or was mined. The loss of life was slight.

Harvard Doctors Sail.—Another detachment of the Harvard Medical School unit, consisting of six surgeons, one dentist and twenty nurses, sailed from New York on November 20 for Liverpool. The group will take the place of the doctors and nurses now on duty at the British base hospital in France. This makes a total of 117 surgeons and dentists and 184 nurses who have been in the service of the unit since it was organized in June, 1915.

After-Care of Paralysis Cases.—A campaign was begun last week to raise $250,000 for a year's care of the 5600 children who were left paralyzed as a result of the poliomyelitis epidemic last summer in New York, and at a meeting held at the Hotel Manhattan to formulate plans for the work addresses were made by Dr. John S. Billings, Dr. John W. Brannan, Dr. Thomas J. Riley and Dr. Virgil P. Gibney.

Clinics at Lebanon Hospital.—Dr. Parker Syms and Dr. M. R. Bookman will hold surgical clinics at Lebanon Hospital, New York, on Wednesdays at 3 o'clock, from November 1 to March 1, to which the medical profession is invited. The hospital is most conveniently reached by the subway, West Farms division, to Jackson Avenue station. A bulletin of the operations scheduled is posted at the Academy of Medicine.

United States Census.—The United States Census Bureau estimates that on January 1, 1917, the population of the country and its possessions will have reached 113,309,285, as against 111,579,952 in 1916. The population of the continental United States at that time is estimated at 102,826,309. The State of New York leads with an estimated population of 10,366,778; Pennsylvania is given 8,591,029; Illinois, 6,193,626; Ohio, 5,181,220; Texas, 4,472,494, and Massachusetts, 3,747,564.

Dr. **Charles A. Powers** of Denver has returned after six months of service as surgeon at the American Ambulance Hospital of Paris. He will resume work there on April first.

Dr. Simon Flexner, director of the Rockefeller Institute, spoke before the Brooklyn Academy of Arts and Sciences on November 23, on the recent epidemic of poliomyelitis, and warned his hearers that the plague might visit New York again, and that physicians, unaided by laymen, were powerless to prevent its vigorous recurrence.

Dr. John Shelton Horsley, surgeon in charge of St. Elizabeth's Hospital, Richmond, Va., has been awarded by the Southern Medical Association a medal for original work in the surgery of blood vessels and intestines.

Fined for Substitution.—For substituting aspirin for phenacetin when compounding a prescription calling for the latter drug, a druggist of First Avenue, New York, was recently fined $100 in one of the city courts.

Medical Society of Virginia.—The forty-seventh annual meeting of this society was held in Norfolk, Va., on Oct. 24 to 27. Officers for the ensuing year were elected as follows: *President*, Dr. George A. Stover, South Boston; *Vice-presidents*, Dr. Charles

S. Webb, Bowling Green; Achilles L. Tynes, Staunton, and William B. Barham, Newsoms; *Secretary*, Dr. Paulus A. Irving, Framville; *Treasurer*, Dr. Mark W. Peyser, Richmond. Roanoke was named as the next place of meeting.

Gifts to Charities.—By the will of the late Mrs. Wheeler H. Peckham of New York, bequests of $10,000 each are made to St. Mary's Free Hospital for Children, the Sea Breeze Hospital and the Morristown Memorial Hospital and All Souls Hospital, Morristown, N. J.

Deaths Abroad.—Dr. Eugene Louis Doyen of Paris, whose method of treating cancer by the injection of a serum attracted widespread attention a few years ago, died at his home after a brief illness on November 21, aged 57 years.

A recent dispatch from Sir William Osler announced the death of Miss Louisa Parsons, a trained nurse who was for many years connected with the Johns Hopkins Hospital. Miss Parsons was trained under Florence Nightingale, and had seen service in Lord Wolseley's Egyptian Expedition in 1882 and in the Spanish-American and Boer wars.

Court Reinstates Physician.—By an order of the District Court of Denver, Col., the name of Dr. Floyd W. Noble of that city, whose license to practise was recently withdrawn, has been restored to the list of practising physicians, and the cancelled license will be reissued. Dr. Noble was charged with murder in connection with the death of a woman in Denver, and was tried and acquitted of the crime by a jury. While he was still under charges, however, his license was revoked by the State Board of Medical Examiners.

Brooklyn Medical Library Association.—The annual meeting of this society will be held on Monday, December 4, 1916, at the Library Building, Medical Society of the County of Kings, 1313 Bedford Avenue, at 8.30 P. M. Dr. Edward E. Cornwall will deliver an address on "Medical Notes of Early New England, 1620-1650."

The Private Pavilion of the Montefiore Home and Hospital was opened with appropriate ceremony on November 20, having been in process of construction for two and a half years. The cost of construction, with suitable equipment, amounting to a quarter of a million dollars, was contributed by four of the directors of the institution. The medical director of the home was responsible for the idea of this special hospital for well-to-do chronic invalids who will there find the comforts of a hotel in addition to treatments which have proven effective in chronic cases, such as hydrotherapy, electrotherapy, mechanotherapy, thermotherapy, and manual massage as well as such medical or surgical care as the case may require.

Rockingham County (N. H.) Medical Society.—The annual meeting of the Rockingham County Medical Society was held in Portsmouth, N. H., on November 9, when the following officers were elected: *President*, Dr. Herbert C. Day, Exeter; *Vice-president*, Dr. George H. Towle, Newmarket; *Secretary*, Dr. Ralph S. Perkins, Exeter; *Treasurer*, Dr. Walter Tuttle, Exeter.

Obituary Notes.—Dr. James D. Wagner of Selma, Cal., a graduate of the medical department of the University of Nashville, in 1873, died at Long Beach, Cal., on October 16, from cerebral hemorrhage, aged 72 years.

Dr. Carl Buttner of Orange, N. J., a graduate of the University of Würzburg, Germany, in 1867, and a member of the Medical Society of the State of New Jersey and the Essex County Medical Society, died at his home on November 16, aged 67 years. Dr. Buttner had been City Physician in Orange, was one of the organizers of the first Board of Health there and was formerly a member of the staff of the Orange Memorial Hospital.

Dr. Thomas Joseph Dunn of New York, professor of clinical medicine at Fordham University, and senior physician to the Fordham Hospital, died at his home on November 23, aged 52 years. Dr. Dunn was graduated from New York University Medical College, New York, in 1888, served for two years as an interne in Bellevue Hospital and later studied in Vienna. He was a member of the American Medical Association, the New York State Medical Society, the Bronx County Medical Society, the Bronx Medical Association and the Society of the Alumni of Bellevue Hospital, president of the Bronx Sanitarium and attending physician to St. Laurence Hospital.

Dr. Marcus M. Franklin of Philadelphia, a graduate of the Jefferson Medical College, in the class of 1870, died on November 6 at the age of 74 years. Dr. Franklin was the first interne appointed to the German Hospital of Philadelphia, and later was visiting surgeon to this institution for fourteen years. He was a member of the Medico-Legal Society of Philadelphia, the Philadelphia Obstetrical Society, the Philadelphia County Medical Society, and the Medical Society of the State of Pennsylvania, and a Fellow of the American Medical Association.

Dr. Frederick L. Grander of Scranton, a graduate of the Jefferson Medical College, in the class of 1885, died on November 4 at the age of 55 years.

Dr. Milton S. McMurtry, Sr., of Clovis, Cal., a graduate of the Missouri Medical College, St. Louis, in 1877, died at his home on October 3, from pneumonia, aged 60 years.

Dr. William Lander Settlemyer of Gaffney, S. C., a graduate of the Kentucky School of Medicine, Louisville, in 1892, died at his home on October 8, aged 49 years.

Dr. William Stiles, Jr., of Philadelphia, Pa., a graduate of the Hahnemann Medical College and Hospital of Philadelphia, in 1875, died at his home on October 7, from uremia, aged 74 years.

Dr. Isaac D. Jones of Murdock, Neb., a graduate of the University of Nebraska, College of Medicine, Omaha, in 1895, and a member of the Nebraska State Medical Association and the Cass County Medical Society, died at his home on October 10, of nephritis, aged 52 years.

Dr. John A. Seapy of Geddes, S. D., a graduate of Bennett Medical College, Chicago, in 1900, and a member of the American Medical Association, the South Dakota State Medical Association, and the Charles Mix County Medical Society, died in St. Mary's Hospital, Rochester, Minn., recently, aged 42 years.

Dr. Edward O. Plumbe of Chicago, Ill., a graduate of the New Orleans School of Medicine in 1869, died at his home on October 22, aged 78 years.

Dr. Elijah Smith Ellzey of Blue Mountain, Miss., a graduate of the Kentucky School of Medicine, Louisville, in 1876, and a member of the Mississippi State Medical Association and the Tippah County Medical Society, died in a hospital in Ripley, Miss., on October 13, aged 68 years.

Dr. EDWIN ELLIOTT of Chesaning, Mich., a graduate of the Detroit College of Medicine and Surgery in 1894, and a member of the Michigan State Medical Society and the Saginaw County Medical Society, died at his home on September 23, from angina pectoris, aged 52 years.

Dr. JOSEPH R. BROWN of Seward, N. Y., a graduate of Albany Medical College in 1868, and a member of the American Medical Association, the Medical Society of the State of New York, and the Schoharie County Medical Society, died at his home on October 13, from arteriosclerosis, aged 68 years.

Dr. CHARLES WESTLY LESTER of Guthrie, Tex., a graduate of Vanderbilt University Medical Department, Nashville, in 1880, and a member of the American Medical Association, the State Medical Association of Texas, and the Todd County Medical Society, died at his home on October 11, from cerebral hemorrhage, aged 58 years.

Dr. ISAAC R. GODWIN of Fincastle, Va., a graduate of the Medical College of Virginia, Richmond, in 1860, and a member of the Medical Society of Virginia, and the Botetourt County Medical Society, died at his home on October 1, aged 79 years.

Dr. JOHN CAMPBELL SPENCER of San Francisco, Cal., a graduate of the College of Physicians and Surgeons, Columbia University, New York, in 1885, and a member of the American Medical Association, the Medical Society of the State of California, the San Francisco County Medical Society, and the American Urological Association, died at his home on October 19, aged 55 years.

Dr. LEE WALTON VERDERY of Augusta, Ga., a graduate of the Medical Department of the University of Georgia, Augusta, in 1911, died suddenly at Fort Sam Houston, Tex., on October 29, aged 28 years. Dr. Verdery was a lieutenant in the hospital corps of the United States Army.

Dr. CHARLES EDWIN STONE of Lynn, Mass., a graduate of the College of Medicine of the University of Vermont, Burlington, in 1906, and a member of the Massachusetts Medical Society and the Essex County Medical Society, died at his home on November 6, after a short illness, aged 48 years.

Dr. HUGH R. GREEN of Delaplane, Va., a graduate of the School of Medicine of the University of Maryland, Baltimore, in 1867, died recently, aged 74 years.

Dr. GEORGE D. STANTON of Stonington, Conn., a graduate of Bellevue Hospital Medical College, New York, in 1865, and a member of the Connecticut State Medical Society and the New London County Medical Society, died on November 4, aged 77 years.

Dr. EMIL HESSEL BECKMAN of Minneapolis, Minn., a graduate of the University of Minnesota Medical School, Minneapolis, in 1901, and a member of the American Medical Association, the Minnesota State Medical Association, the Olmsted County Medical Society, the American Surgical Association, the Western Surgical Association, and the American College of Surgeons, died at his home on November 7, from blood poisoning, aged 44 years.

Dr. PHIL C. NAUMANN of Burlington, Iowa, a graduate of the State University of Iowa, College of Medicine, Iowa City, in 1887, died near his office on October 16, from cerebral hemorrhage, aged 55 years.

Dr. RICHARD H. PARSONS of Mount Holly, N. J., a graduate of the department of Medicine of the University of Pennsylvania, Philadelphia, in 1880, and a member of the American Medical Association, the Medical Society of New Jersey, the Burlington County Medical Society and the American Medico-Psychological Association, died in the Mercer Hospial, in Trenton, on November 12, from pneumonia, aged 57 years. Dr. Parsons had been medical superintendent of the Burlington County Hospital for thirty years.

Dr. FRANCIS J. BOCK of Lancaster, Wis., a graduate of the Hahnemann Medical College and Hospital of Chicago, in 1906, and a member of the State Medical Society of Wisconsin and the Grant County Medical Society, died on October 18, aged 41 years.

Dr. CLARIUS CONFUCIUS BIRNEY of Mason City, Iowa, a graduate of Rush Medical College, Chicago, in 1874, died at his home on October 21, from nephritis, aged 69 years.

Dr. JOEL V. SAMPSELL of Elyria, Ohio, a graduate of the Jefferson Medical College of Philadelphia, in 1877, died at his home on October 20, aged 65 years.

Dr. FRANCIS J. KEANY of Boston, professor of dermatology in Tufts College Medical School, and a trustee of the Boston City Hospital, died at his home on November 23, aged 48 years. Dr. Keany was graduated from the Harvard University Medical School, Boston, in 1892, and was a member of the Massachusetts Medical Society and the Suffolk District Medical Society.

Dr. WALTER S. SUTTON of Kansas City, Mo., a graduate of Columbia University, College of Physicians and Surgeons, New York, in 1907, and a member of the American Medical Association, the Kansas Medical Society, the Missouri State Medical Association, the Jackson County Medical Society, American Association of Anesthetists and the American College of Surgeons, died on November 11, following an operation for appendicitis, aged 39 years. Dr. Sutton was Associated Professor of Surgery in the University of Kansas, School of Medicine, Lawrence and Rosedale.

Dr. CHARLES H. TODD of Owensboro, Ky., a graduate of Tulane University of Louisiana, School of Medicine, New Orleans, in 1861, and a member of the American Medical Association, the Louisiana State Medical Society, and the Daviess County Medical Society, died suddenly at his home on November 12, from heart disease, aged 78 years.

Dr. ALBERT CRANDALL WAY of Perry Center, N. Y., a graduate of the Department of Medicine of the University of Buffalo in 1895, and a member of the American Medical Association, the Medical Society of the State of New York, and the Wyoming County Medical Society, died at Evergreen Lodge, Saranac Lake, on November 5, from tuberculosis, aged 46 years.

Dr. GUERT M. TINKER of Sharon, Pa., a graduate of the University of Pennsylvania, School of Medicine, Philadelphia, in 1894, and a member of the American Medical Association, the Medical Society of the State of Pennsylvania, and the Mercer County Medical Society, died at his home on November 9, from blood poisoning, aged 47 years.

Dr. ARTHUR S. TOWNSEND of Bennettsville, S. C., a graduate of the Medical College of the State of South Carolina, Charleston, in 1887, and a member of the South Carolina Medical Association and the Marlboro County Medical Society, died at his home on November 12, aged 53 years.

Dr. HENRY K. LEAKE of Dallas, Texas, a graduate of the Kentucky School of Medicine, Louisville, in 1869, and a member of the State Medical Association of Texas and the Dallas County Medical

Society, died at his home on October 29, from nephritis, aged 69 years.

Dr. JULIUS H. EICHBERG of Cincinnati, Ohio, a graduate of the Miami Medical College, Cincinnati, in 1889, a member of the American Medical Association, the Ohio State Medical Association, and the Hamilton County Medical Society, and professor of materia medica, pharmacy and therapeutics in the University of Cincinnati, College of Medicine, died at French Lick Springs, Ind., on November 2, from heart disease, aged 57 years.

Dr. HENRY H. WHITAKER of Hilliardston, N. C., a graduate of the School of Medicine of the University of Maryland, Baltimore, in 1883, and a member of the Medical Society of the State of North Carolina and the Nash County Medical Society, died at his home on October 12, from cerebral hemorrhage, aged 55 years.

Dr. ROBERT C. WESTPHAL of Yorktown, Texas, a graduate of the Starling Medical College of Columbus, Ohio, in 1902, and a member of the American Medical Association, the State Medical Association of Texas, and the Dewitt County Medical Society, died in Cuero Hospital on October 21, after an operation, aged 46 years.

Dr. SILAS F. ROBERTS of Glencoe, Ohio, a graduate of the Hospital College of Medicine, Louisville, in 1895, was killed by a train at a grade crossing in Glencoe on October 26, aged 47 years.

Dr. JOHN SALTENBERGER of Millstadt, Ill., a graduate of the Washington University Medical School, St. Louis, in 1864, died at his home on October 20, from heart disease, aged 84 years.

Dr. WILLIAM H. DUKEMAN of Los Angeles, Cal., a graduate of New York University Medical College in 1880, died suddenly on October 22, from heart disease, aged 61 years.

Dr. WILLIAM H. CONIBEAR of Lakeland, Fla., a graduate of Rush Medical College, Chicago, in 1876, and a member of the Illinois State Medical Society, the Florida Medical Association, and the Polk County Medical Society, died at his home on October 25, from carcinoma of the liver, aged 73 years.

Dr. WILLIAM DAVID ALDRICH of Albany, N. Y., a graduate of the Albany Medical College in 1910, died on September 28, aged 33 years.

Dr. NEAL L. BURGESS of Sumner, Texas, a graduate of the Memphis Hospital Medical College, Memphis, in 1909, and a member of the State Medical Association of Texas and the Lamar County Medical Society, died at his home on November 1, from cerebral hemorrhage, aged 39 years.

Dr. JULIUS D. ABBOTT of Bethel, Ohio, a graduate of the Cincinnati College of Medicine and Surgery in 1874, died in Christ Hospital, Cincinnati, on October 22, aged 71 years.

Dr. PRICE PATTERSON of Maysville, Okla., a graduate of the Memphis Hospital Medical College, Memphis, in 1901, and a member of the American Medical Association, the Oklahoma State Medical Association, and the Garvin County Medical Society, died suddenly at Maysville on October 28, aged 53 years.

Dr. JOHN D. MCCOLLUM of Alpharetta, Ga., a graduate of Atlanta Medical College in 1884, died at his home on October 16, aged 55 years.

Dr. JOHN JAMES MASON of New York, a graduate of Bellevue Hospital Medical College, New York, in 1869, died at his home on November 22.

Dr. MARIE F. ROSE of Harvey, Ill., a graduate of the Hahnemann Medical College and Hospital of Chicago in 1896, died at her home on October 11.

Correspondence.

HEXAMETHYLENE TETRAMINE AS A FUEL.

TO THE EDITOR OF THE MEDICAL RECORD:

SIR:—There are many times when the physician needs a small, hot, sootless flame such as produced by an alcohol lamp, when he is out of reach of any such article. It is not generally known, I believe, that hexamethylene tetramine will give exactly this kind of flame when ignited. Two five-grain tablets such as are often carried in the physician's medicine case, will give a clean flame of sufficient heat to boil 5 c.c. of water in a test-tube within 30 seconds, and of sufficient duration to keep it boiling for two minutes. For boiling needles or small instruments, sterilizing water for hypodermic injections, testing for albumin by the heat-and-acid method, and many other similar purposes, this "extemporaneous technique" may be found useful.

LOWELL C. FROST, M.D.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

NOTIFICATION—REPORT OF ROYAL COMMISSION—COMPULSION—AUSTRALIAN PLAN—DANGER OF DRIVING MEN TO QUACKS—EFFECTS DISASTROUS—DIFFICULTIES OF PREVENTING ILLEGAL PRACTICE—MEDICAL SOCIETY OF LONDON'S MEETING.

LONDON, October 28, 1916.

THE general subject of notification of venereal diseases is freely discussed in the Report of the Royal Commission. Among the diseases compulsorily notifiable by the medical attendant, smallpox, scarlet fever, typhoid fever, diphtheria, etc., are to be also reported by the householder. This last duty has not been strictly enforced—in fact, it hardly can be, for it can seldom be proved that the householder knew what the case actually was. If a similar system of notification were applied to gonorrhea or syphilis, it seems obvious compulsion to report could scarcely be enforced against either the patient or the householder; concealment would be so easy and even if brought to light ignorance of the special character of the ailment could almost always be successfully pleaded. If notification is to be enforced it must be against the doctors who are treating the cases. In view of the strong motives for concealment and the relationship of medical men to their patients it is probable that compulsion would not be really effective in more than a very small minority of the total cases. Here the question arises that if all cases passing through a doctor's hands were reported, *cui bono?* The patient is already under medical care and presumably receiving the treatment best calculated to render him rapidly free from infection. In Australia a modified system of notification is being tried and the reports of it deserve attention. The doctor is required to notify under a number and initials only, but if the patient discontinues treatment before he is cured, the doctor must give his name and address to the medical health officer of his district. It is hardly likely that this scheme can be carried out in these islands. If attempted it would probably drive many patients to irregular practitioners. The chief difficulty in eradicating venereal diseases and preventing their consequences, is to overcome the reluctance to consult a doctor. If the patients knew that he was obliged to report their case to the medical health of-

ficer their reluctance would only be increased and they would resort to quacks in still greater proportion than they now do. It is the great number who at present do so resort, especially in the early stages, that defeats the measures of treatment, as it does those of prevention.

The Royal Commission had before it abundant evidence of the mischief done by unqualified persons. The earlier symptoms of constitutional infection may be so slight that the patient deludes himself into the belief that they are not due to syphilis and only need a little cooling medicine which he gets from a druggist and fondly thinks he is well. But later on he is told that he is "as old as his arteries," he feels himself old, perhaps at fifty and soon afterwards some constitutional disease attacks him. His wife, too, gets out of health and if she becomes pregnant the baby is born dead or if alive, in such a state that its birth is regarded as a calamity. To permit the treatment of these diseases by ignorant persons is to suffer them to carry disablement and death in various directions. The Royal Commissioners have no hesitation in stating that the effects of unqualified practice in these diseases are disastrous and they add that the continued existence of this unqualified practice constitutes one of the principal hindrances to the eradication of those diseases. The medical officer of the Local Government Board suggested that chemists and other unqualified persons should be forbidden to treat these diseases or any disorder of the genito-urinary organs; and the commission in their report affirmed that they would have advocated legal means of preventing it, but for the practical difficulties. One asks here, should they not have devised the means of overcoming those difficulties? Surely they might at least have made some suggestion.

The session of the Medical Society opened on the 9th inst. when the new president, Lt.-Col. D'Arcy Power, F.R.C.S., delivered an address on "John Ward and His Diary," opening it with a quotation from one of the sixteen notebooks in possession of the society, from which Dr. Severn published extracts in 1839. Col. Power has examined the earlier volumes and finds them as it were common place books of a writer living at Oxford from 1652 to 1660, a period when nearly all the original members of the Royal Society were Oxford residents. The president hopes to return to this subject on another occasion.

1. Mental Pitfalls of Adolescence.—Henry R. Stedman gives a clear picture of the most important of these pitfalls, namely, dementia precox, and considers that widespread information on the subject is plainly called for in view of the large number of youths and girls who are annually admitted to state and private hospitals for mental disease, and the ignorance of the general public as regards the special form of the disorder which is peculiar to adolescence. The young are protected by education in physical and moral hygiene, but against mental deterioration and breakdown little or no warning or advice is given him or his parents, until he is placed under care in an institution. Of the 3,264 *new* cases of mental disease admitted to the Massachusetts hospitals in 1915, 804, or over 21 per cent. were suffering from dementia precox. These cases represent one-third more admissions than the combined totals of all patients whose mental condition is due either to alcohol or syphilis—causes which are very rarely operative in producing this form of mental disease. Of all the classified forms of insanity, dementia precox claims by far the greatest number of victims. This mental condition must not be confounded with mental defect or feeble-mindedness proper. The latter has little or no mind to start with, while the dementia precox cases enjoy, up to the time of their breakdown, apparently normal and sound minds. They most frequently display marked intelligence and promise. It is during the period or at the end of adolescence, the most critical period of mental life, ranging in age from 15 to 25, that dementia precox begins. It may originate a little later, though rarely. The disease has been divided into several different sub-varieties, but the simpler form is the one most met with outside of hospitals. These cases are less striking and very insidious in their development. The principal feature is the change in the youth's character, in the shape of a gradually developing mild apathy and indifference. The well-cared-for patient leads a life of indolence varied by times of aimless activity and tends to develop obsessions, antagonisms, and anti-social proclivities. The poorer patient develops into either a tramp, a crank, a criminal, or prostitute in the making. Wilmans found in 127 vagabonds 66 cases of this condition. The first symptom seems to be lapse in power of attention, of mental concentration. A very definite outline of symptoms is given by Stedman and he says the general appearance of the patient is that of apathy or mild depression, except at times of unexpected and transient animation. Lack of energy also is constant, except at intervals. Their tendency to shrink from coping with the world, due to a faulty habit of adjustment, resolves itself into the "shut-in" personality which typifies these cases. Hoch found this type of personality markedly pronounced in 35 per cent. and indicated 16 per cent. out of 72 cases of dementia precox. Another type is the precocious youth who is liable to mental breakdown in adolescence due to the overstimulation of a too active mind. Badly directed education, moral and mental, may give a wrong turn to the tendencies of the nervous child and thus leave him with little defense against the exciting causes of mental disease when adolescence is reached. Overstudy, rapid and excessive growth in height, without corresponding weight and development, are recognized as abnormal. There is not sufficient alimentation provided to meet the demand of the growth of the organism *plus* excessive mental and bodily energy. Contrary to popular opinion, masturbation is almost never the cause of mental defect or disease. Typhoid and other debilitating diseases occasionally leave the patient in a permanently weakened mental condition culminating in dementia precox; also cases of puerperal insanity are really many times cases of dementia precox superinduced by the strain of childbirth. Stedman suggests that the outlook for recovery in these cases is gloomy, but that properly instituted preventive measures may decidedly change the prognosis. Young cases taken at the beginning of the condition and properly treated show marked improvement and many have been able to resume normal life and duties, while others not reaching the normal have at least been able to lead

quiet lives of usefulness. Campbell says that "the researches of Kraepelin, Freud, and Jung of Germany, and Meyer and Hoch in this country, show that under proper control many cases of functional disease and insanity are of such a nature as to be manageable and preventable." Campbell considers cases of dementia precox as the most hopeful and classes 39 per cent. as manageable and preventable. These cases must be given a congenial environment as to mental and physical health and kept from over-exertion and fatigue. Plenty of thoroughly nourishing food and sleep and the companionship of their fellows will do much to ward off or overcome this mental condition. Fresh air should be the breath of life of the young. Sir Thomas Clouston has said that fatness, self-control, and orderliness are the three most important qualities for these patients to aim at. Stedman concludes by stating that during the period of adolescence all boys and girls should be carefully guarded and not allowed to undertake a life beyond their strength and capacity, whether it be social service work, a life of social gayety, or, as in the cases among the poorer classes, too hard work and too little nourishment. Fortunately state prevention and hospitals are doing much to recognize and improve this period of life for the young.

4. **The Etiology of Scarlet Fever.** — F. B. Mallory states that the primary lesion of scarlet fever is located in the respiratory tract, starting usually in or round the tonsils. In severe cases it may extend farther down to the bronchi or esophagus. Study of the lesions of scarlet fever shows the presence in them of a delicate gram-positive bacillus in large numbers. In both smears and culture the bacillus is slighly smaller than the diphtheria bacillus, and varies from coccus-like to large bacillary forms. The organisms isolated are facultative aerobes, and grow best anaerobically upon serum-glycerin (3 per cent.)-dextrose (0.5 per cent.)-agar. Less abundant growth upon other media occurs. After further description of the habits of this bacillus he concludes that it seems reasonable to infer from these observations that scarlet fever may be due to a strongly gram-positive bacillus (*B. scarlatinæ*), which is less virulent than the diphtheria bacillus, but which infects practically the same localities and in severe cases may extend in the same way to adjoining tissues, especially the larynx, trachea, and lungs. The toxin causes necrosis and desquamation of the covering epithelium and leads to an exudation of serum and polymorphonuclear leucocytes. Fibrin formation is usually absent or slight. On this account the primary gross lesions are inconspicuous and easily overlooked. There is usually little membrane formation to call attention, as in diphtheria, to the lesions. The bacillus of scarlet fever usually dies out quickly in the lesions, so that after the second or third day following the eruption it is often difficult or impossible to demonstrate it; but it opens the way for streptococcus invasion and seems to favor its growth.

3. **Diagnosis of Duodenal Ulcer.**—A. Everett Austin refers to the difficulties encountered in the diagnosis of this condition, as evidenced by the results of autopsies on cases supposed to have been suffering from duodenal ulcer when the condition was but rarely found. It is conceivable, Austin says, that a duodenal ulcer may spontaneously undergo so complete a cure that the scar tissue which is left may be fully absorbed and hence escape the attention of the pathologist. The operation naturally takes place during the period of activity, and it is surprising the unerring accuracy with which a competent surgeon, with hands incased in rubber gloves, can detect indurations in the duodenum resulting from this form of ulcer. Austin enters minutely into a description of the symptoms of this condition and the results in diminution of symptoms on taking food. For results of his work he refers to thirteen of his own cases which have furnished the material for his investigations. From these results he says that it seems that a diagnosis of duodenal ulcer must be based largely upon the four factors of periodical and characteristic fasting discomfort, if not pain, on the presence of hypersecretion, particularly of the alimentary variety rather than the continuous; on the presence of occult blood in the stool, and on distortions of the first part of the duodenum, as shown by the radiogram. A short perusal of any series of cases will soon show that all of these are never found in any one case. When, however, any two or three are present, we may well forego the presence of the fourth factor. The relative value of the history, of the character of the pain and its intermissions, and the detection at some time of occult blood in the stools, appears to Austin to be of the most importance. On account of the close similarity of symptoms of duodenal ulcer and functional hypersecretion, the former lose much of their significance, and dependence must be placed more upon physical signs than upon symptoms; and as hypersecretion is present, both as a functional disorder and as the outcome of ulcer, the conclusion must be made that occult blood in the stools and the distortion of the duodenum as shown by the *x*-ray examination are the positive signs upon which diagnosis must largely be based. As far as differential diagnosis is concerned, there is probably no condition which so closely simulates duodenal ulcer as cholelithiasis, but one of the most distinctive points of difference is the slight trace of bile found in the urine when the common duct and gallbladder are involved. In typical gallstone colic the pain reaches a severity which is never found with duodenal ulcer. Icterus is common with cholecystitis, while occult blood is more typical of duodenal ulcer. The distinction between gastric ulcer and duodenal ulcer is often impossible, and Austin considers it a mere refinement of diagnosis at times to reach a decision. With reference to this condition and appendicitis much may be said, but the writer considers that the diagnosis of diseased appendix is often made in error on account of the reflex relations of the plexuses involved, and that unless undoubted evidence of disease in the right lower quadrant is present, with other typical symptoms, it is much wiser to let the surgeon make the median incision and examine the region of the duodenum, at the same time removing the appendix if the duodenum is found normal. At least, confusion occurs only with the so-called chronic condition or appendicitis larvata.

4. **The Value to the Operating Surgeon of a Thorough Understanding of Therapeutic Agents.** — Albert Vanderveer, in giving his opinion on this subject before the American Therapeutic Society, considered that in general surgery the men of the future who accomplish success will be those who give the best that is in them to the study of surgical bacteriology. He expresses regret for the tendency of some of the younger men in the profession to lose interest in their cases when once

they have touched upon a surgical lesion and consider the case but fit for the surgeon. In many such instances more persistent investigation would have demonstrated that therapeutic measures following a correct diagnosis would have obviated the necessity for an operation. A study, complete as possible, of all cases, employing every means at hand as an aid in diagnosis, is due the patient from a practitioner. He cites the thoroughness of the examinations of the Mayo clinic before operation is decided upon. Cases are given showing how easily symptoms may be misinterpreted, and how such cases were cured therapeutically, when they might have been sent to the surgeon had not careful study of symptoms detected the true causes. He asks that may it not be said that there will always be a border-line of cases in which both medical and surgical diagnosis may be questioned.

9. The Spinal Fluid of Normal Children. — O. H. Petty, having procured and examined spinal fluids in nearly fifty cases of infantile paralysis, was impressed with the fact that the fatal and severer forms of the disease as a rule showed a lower pressure—that is, fewer drops a minute from the spinal needle—than the apparently milder types of the disease. This fact suggested to him the question of the normal fluid; so, finding no detailed records of a large series of normal fluids, he has begun the study on a series of normal children, comprising so far a few less than twenty. The average results are almost startling. They are as follows: Pressure close to 20 mm. Hg.; cell count approximating eleven cells per cubic millimeter, and the number of drops of spinal fluid a minute usually being above seventy-five. Up to this time the normal pressure has been considered as from 6 to 8 mm. Hg., the number of drops a minute as about twenty, and a cell count above six per cubic centimeter as pathological. After a sufficient number has been studied to determine a constant average, they will be reported in detail, showing pressure as recorded by a mercurial manometer, both with and without general anesthesia, drops a minute with gage of needle used, and cell count.

1. **Results of Recent Studies on Ductless Glands.**—W. B. Cannon states that the studies which have been carried on for the past four or five years in the Harvard Physiological Laboratory with reference to the bodily changes which accompany strong emotions, such as fear and rage, have revealed interesting relations between these emotions and certain glands of internal secretion, and have suggested also a way in which emotional excitement may occasion pathological states. When a cat becomes infuriated the pupils are dilated and the hair is erect from head to tail; the heart beats rapidly and the activities of the stomach and intestines are stopped. Both internal and external changes are due to the passage of nerve impulses to viscera along the nuerons of the sympathetic division of the autonomic system. The relation of the fibres connecting the central nervous system with these neurons is such as to provide for diffuse action on all the viscera that are innervated by this division. He explains the sympathetic control of the suprarenal glands, and that they have found that these glands secrete epinephrin in times of great excitement, also that there is an increased liberation of sugar from the liver so that glycosuria may result, that there is an abolition or prompt lessening of muscular fatigue, and that there is much more clotting of blood. Epinephrin also causes a redistribution of blood in the body, sending it away from the alimentary canal, whose activities are inhibited, to the heart, lungs, the central nervous system and active skeletal muscles; dilation of the branchioles and increase in the number of red blood corpuscles per cubic centimeter are all the result of its action under emotional excitement. These changes are the same in man as in the animals and produce reinforcement for the great power and endurance which are exhibited in times of intense excitement. Physiological activity is accompanied by the presence of an electrical difference which may be observed by connecting an active part with an inactive part of the body through a sensitive galvanometer. Through this method the glandular secretions have been studied and when applied to the thyroid, the positive testimony of the galvanometer is evidence of thyroid secretion, and that the gland is subject to impulses from a part of the sympathetic division of the autonomic system, the cervical sympathetic. Experiment further shows that the thyroid is stimulated by the epinephrin produced by the suprarenals in times of intense excitement. Experiment also showed that the efficiency of epinephrin is not produced if the thyroid glands have been previously removed. Thus a hormone relation between the suprarenal and the thyroid is clearly demonstrated. Two questions have arisen in the course of this work: Why are organs which are disturbed in times of emotional stress not disturbed at other times? It seemed probable that they were protected from interference by a high neuron threshold interposed between the central nervous system and the visceral cells. Consequently only when great excitement is present in the central nervous system is this threshold crossed and the changes in the viscera brought to pass. Why, in certain pathologic cases is there apparently frequent or continuous disturbance of the same viscera? Possibly due to a wearing down of the high threshold here or there from frequent or great emotional experiences. Thus dyspepsia, tachycardia and possibly persistent glycosuria, reported as having an emotional origin, might be accounted for. Experiments are given by Cannon and the evidence presented shows that besides any routine function, the suprarenal gland has an emergency function brought out in times of great excitement. It is not unreasonable to suppose that the thyroid gland likewise has an emergency function evoked in critical times, which would serve to increase the speed of metabolism when the rapidity of bodily processes might be of the utmost importance and augmenting the efficiency of the epinephrin which would be secreted simultaneously.

5. **The Relation of Diet to Beriberi.**—Edward B. Ved-

der, in considering this subject and the present status of our knowledge of the vitamines, says that the consensus of opinion is that beriberi is caused by a dietary deficiency resulting from faulty metabolism caused by the lack of certain accessory food substances called vitamines. He reviews the work of many of the investigators in this field and credits Funk with the application of the name vitamine to the accessory food substance, the lack of which produces this disease. But Funk and Drummond did not succeed in isolating the pure vitamine; but Williams succeeded later by a synthetic method in preparing a pure substance that would cure polyneuritis in fowls corresponding to the pure vitamine. Williams and Seidell have found that a similar isomerism existing in these substances also exists in the vitamine of yeast and is primarily responsible for the instability of these compounds, which has so far prevented their isolation. Adenin is the purin base in yeast, which has this property of isomerism. With regard to the antineuritic vitamine Vedder has proposed the hypothesis that this chemical substance acts as a building stone of the complex structure of the nervous tissue, without which it cannot be repaired. When a deficiency in this vitamine exists the nervous tissue becomes first exhausted and then degenerated until finally the symptoms of polyneuritis appear in fowls or dry beriberi in man. This theory is based on experimental observations in man. The antineuritic vitamine is the only one of the accessory food substances concerning which there is sufficient evidence to even theorize concerning its action in the body, and more work will be needed before any adequate conception of the physiological action of the vitamines will be known. The study of beriberi, scurvy, and other deficiencies has given a working basis that there are a number of different accessory food substances or vitamines and that each deficiency disease is caused by the absence of its particular vitamine. Vedder, from his own experiments and those of other investigators, considers that we must assume that there is a whole group of these vitamines, but that further investigations will be necessary to determine the relation of these various substances to each other. The study of dietetics from the point of view of the vitamines has only just begun, and the exact rôle they play in metabolism has not yet been elucidated, but it has been clearly demonstrated that certain deficiency diseases are due to the lack of certain accessory foods. Pellagra, beriberi, scurvy, and other deficiency diseases are to be controlled or prevented through the administration of the proper foods containing the adequate vitamines. Vedder suggests a number of foods and dietary rules for use in order to prevent these deficiency diseases: In any institution where bread is the staple article of diet, it should be made from whole wheat flour. Rice used in any quantity should be of the brown undermilled variety. Beans, peas, or other legumes known to prevent beriberi, should be served at least once a week. Canned beans or peas should not be used. Some fresh vegetable or fruit should be issued at least twice a week, and barley, a known preventive of beriberi, should be used in all soups. Cornmeal should be of the yellow or water-ground variety, that is, made from the whole grain. White potatoes and fresh meat should be served at least once a week, preferably once daily, as they prevent scurvy and beriberi. The too exclusive use of canned goods must be carefully avoided.

8. **The Treatment of Malignant Disease About the Mouth by Combined Methods.**—George E. Pfahler confines his remarks entirely to the therapeutic side of these conditions, and considers that physicians should give careful attention to the condition of the mouths of patients, insuring proper care to any apparent minor pathological condition from any cause. Syphilitic conditions need special supervision. No single method is sufficient for the treatment of malignant conditions, and four methods are available, namely, surgical removal, local destruction by means of electrothermic coagulation, deep roentgenotherapy, and the application of radium in the mouth. Every case of epithelioma about the mouth should be destroyed locally by electrothermic coagulation, or thoroughly excised surgically, the preference being given to the first method; but when palpable metastatic glands are present in the neck they should be excised surgically even though the disease in the mouth or lips is destroyed electrothermically. Then deep roentgenotherapy should be thoroughly applied over the wound and over the glandular area, making use of as much crossfiring as possible. The surgical procedures are too well known to need mention here. The electrothermic coagulation differs from the thermocautery in that the heat is generated in the tissues and is produced by the resistance offered to the flow of electricity through the tissues, while the thermocautery is merely transmitted heat and produces a more superficial effect. The effect can be thoroughly controlled by varying the relative sizes of the electrodes so that one can make the conductive heat approximate a cone or cylinder. When one of the electrodes is a point the greatest amount of destruction will develop at the point, and then will radiate in a more or less cone shape toward the opposite electrode, thereby giving a zone in which the tissues are heated to the destructive degree for malignancy, but in which healthy tissues will not be destroyed. Pfahler gives the technic of the application and the advantages of the electrothermic coagulation, which are as follows: The disease is destroyed by conductive heat, which gives a zone of devitalization without actual destruction of healthy tissue, hence saving local tissue when necessary. There are no raw tissues to permit the transplantation of malignant cells. There are no blood or lymphatic vessels opened up through which the disease can be disseminated during the operation. There is no hemorrhage to contend with, though, in tongue cases there is some danger of secondary hemorrhage. There are no open wounds and no danger of infection. The disadvantages of this method of treatment are: There is complete destruction of all the tissue between the two electrodes; therefore there is no chance of saving the blood vessels or nerves which are in close proximity to the disease. Sloughing and foul odor are present during the first two or three weeks. Considerable pain is present during the first few days after the operation. An open area of tissue is left which is healed by granulation, but which at times must be followed by a plastic surgical operation to close the mouth or correct some deformity. In deep roentgenotherapy the object is to control or destroy the out-lying cells or metastases in the coagulation process. Hence the treatment must be thorough and given with the understanding that disease may still be present; for if the disease has been eradicated there is no need of this method. This treatment must always be given with the technic used for deep disease. Pfahler believes that the place of radium in the treatment of malignant disease about the mouth is within the mouth and not on the outside. He can see no advantage of radium over Roentgen rays, and much disadvantage because so much less in quantity, and so less definitely controlled when applied externally. When the radium is applied inside the mouth there is no disadvantage in its use, for the radium can easily be brought in close contact with the disease when filtered through at least

0.5 mm. of silver, and when there is applied approximately 600 milligram hours of radium a decided beneficial effect can be obtained. Many cases of relief and cure are cited and following conclusions given: The cases forming the basis of this report, excepting those involving the lower lip, were almost entirely inoperable, and therefore every success is a distinct advance and every failure only a loss of time, energy, and effort. Combined treatment by surgery, electrothermic coagulation, radium and deep roentgenotherpy will cure some patients who are otherwise hopeless.

13. **Clinical Value of Complement Fixation in Tuberculosis.**—H. R. Miller says that it is well known that in most bacterial diseases the body reacts by the formation of antibodies, and when this takes place the presence of these antibodies can be detected in vitro by a number of different methods, and perhaps the most important of all, the various methods of complement fixation. He reviews the work already done in this field, together with his results and concludes that we have, in the complement fixation reaction, a method for the detection of active tuberculosis. 1. The reaction is practically always positive in active tuberculosis: 284 pulmonary cases: positive in 275, negative in nine. 2. Nontuberculous and normal patients react negatively: 144 cases: all negative. 3. The serums of syphilitics who have no clinically active tuberculosis are negative. Two hundred and forty-three positive Wassermann cases were all negative except seven, and in these seven tuberculosis was established in five cases and was not excluded in the other two. 4. The test is, as a rule, negative in arrested cases. Of 113 serums tested, 103 were negative and 10 positive. 5. The von Pirquet and intradermic tuberculin tests and the complement fixation reaction are not identical or similar diagnostic procedures, since the former indicates the existence of a tuberculous lesion whether old and arrested or active, while the latter points clearly to the presence of some active focus. 6. There is evidence to believe that there exists a group of tubercle bacillus carriers who have no manifestations of clinical activity and whose serums contain no antibodies, and yet discharge tubercle bacilli in their sputum. 7. The presence of tubercle bacilli in the sputum is not an absolute guarantee of the activity of the pulmonary tuberculosis. We feel reasonably justified, therefore, in assuming that the complement fixation test with our antigen may be of distinct aid in the diagnosis of early tuberculosis and in the detection of the disease when the condition is obscure. The test should offer a wide field of usefulness in prognosis, since the reaction loses its intensity of fixation as the patient progresses toward recovery. Lastly, in the fixation test the practitioner will have at his disposal a measure for the control of tuberculosis in institutional and private life.

14. **Epidemics of Pemphigus Neonatorum in Chicago.**—Frederick H. Falls states that there occurred eight small epidemics of this condition in Chicago last year. The disease is an epidemic staphylococcic vesicular dermatitis usually occurring in new-born babies from the fourth to the fourteenth day, but capable of being transmitted to older children and adults. The disease is highly contagious and can he transmitted through a third party, not infected, but in contact with patients having the disease. No cases have been reported in babies who have not been exposed directly or indirectly to the cases developed in the hospital epidemics. Prompt isolation with quarantine of the obstetric wards until the last patient has left the hospital, followed by fumigation and painting, etc., is necessary. Special nurses are necessary on these cases. An efficient method of treating the lesions is to rupture the vesicle as soon as it forms and to apply 2 per cent. ointment of ammoniated mercury to the lesion. Prophylactic and curative vaccines in doses of 15 millions are being tried, but their use is too limited to permit of any definite conclusions as to their value in preventing or effecting a cure of the disease.

2. **Penetrating Wounds of the Abdomen.**—T. Crisp English states that gunshot wounds of the abdomen form a subject of considerable importance, for there has been a decided difference of opinion as to the best line of treatment; some strongly urge operative measures whenever possible, and others believe that for most cases expectant treatment offers the best prospects. Extreme views in either direction will prove to be wrong, but the value of operative treatment under proper conditions is becoming increasingly obvious. English writes from Salonika and says that the only considerable experience of abdominal injuries is that gained in France, and in framing conclusions we must draw largely from that experience, remembering that surgery in France is done under favorable conditions at the present time. It has been suggested that there is a tendency to attach undue importance to these injuries, considering that they form only a small proportion of the total number of wounds. English says, however, that anyone who has come into close contact with numbers of men recently wounded cannot but recognize the importance of the abdominal group; the cases owe this importance to their urgency, their high mortality, and to the fact that many lives may be saved by appropriate treatment. The multiplicity and severity of the lesions make a high mortality inevitable, whatever treatment be adopted; this fact is quickly grasped when one sees the extent of the injuries as revealed on the operating table or in the postmortem tent. Available statistics all emphasize the same fact. From the army statistics English quotes that in 100 cases of abdominal wounds, 65 were instances of penetrating wounds—namely, 30 that died in the field ambulances, and the 35 diagnosed as penetrating cases in the clearing stations; 11 of these ultimately reached England. The mortality up to that stage was about 83 per cent. In civil life operation is the general rule, if conditions permit it. In the early part of this war surgical work was influenced by the South African war traditions, which naturally led surgeons to believe that expectant treatment would give better results than operative treatment. War conditions at the beginning were unfavorable for operative treatment, hence the high mortality discouraged operation. Since the spring of last year, when siege warefare had become established, operative treatment was restarted and every facility that could be devised was supplied. English, from his own surgical experience, divides these cases that are unfit for operation into four groups, those moribund on arrival; in injuries of the liver and kidneys when there was a certainty that the hollow viscera had escaped, operation seemed contraindicated; in the diaphragmatic group in which the projectile appeared to have traversed the top of the abdomen, the diaphragm, and the lower part of the chest, expectant treatment is usually the wisest plan. Cases now reaching the base hospitals have been sent there when apparently con-

valescent from operation, or if without operation when apparently safe from serious trouble. One may assume that the base mortality will be substantially reduced and the total improvement in the mortality reach 20 per cent. over the original. English concludes as follows: 1. Operations for penetrating abdominal wounds are not advisable unless they can be done in good surgical surroundings and by an operator with some knowledge of abdominal surgery; otherwise disasters will be more frequent than successes. 2. Patients with abdominal wounds should be sent to an operating station as quickly as possible, provided that they are fit to travel; their prospects depend mainly on the quickness with which this can be done. 3. Patients who are not fit to travel should be kept absolutely quiet, warm, and under the influence of morphia; saline infusion, hypodermically or otherwise, is most beneficial. They are then transported to the operating station as soon as their condition improves; the question is usually settled by the character of the pulse. If the pulse-rate is 130 or over, it is certainly best to keep them in the place where they are receiving their primary treatment until improvement occurs. 4. On reaching the place where they can be operated upon patients whose condition is good should be dealt with at once, otherwise two to eight hours should be spent in preparative treatment. Operation is never advisable if the pulse-rate is 140 or over. 5. The abdominal exploration must be systematic and quick: the duration of the operation should rarely exceed 45 minutes. 6. When good surgical conditions are obtainable operation is the best treatment in most cases, and must be done as soon as the patient's condition allows it. Be prepared for a high mortality, but know that early operative treatment will substantially reduce it.

5. The Occasional Absence of a Rise of Temperature Following the Administration of Diagnostic Doses of Tuberculin.—Forbes and Hutt report two cases in tuberculous persons where tuberculin was used for diagnostic purposes and no rise of temperature occurred. They say that it is well recognized that a local reaction and rise of temperature following the administration of tuberculin does not necessarily indicate the presence of an active lesion, signs of a focal reaction alone giving any evidence likely to be of assistance in the diagnosis. On the other hand, many believe that active disease can definitely be excluded if the usual diagnostic doses of tuberculin are not followed by any rise of temperature. Their reason for this report is to emphasize the fact that patients suffering from active tuberculosis and who have not been previously treated with tuberculin may have no rise of temperature of even 1° F. above normal following the administration of diagnostic doses of tuberculin. The first was that of a man 44 years of age, and the second was a boy of 2 years. In the first case there were signs only of impaired resonance in the right apex, but history of a cough off and on for the past ten years. Six gradually increasing doses of tuberculin were given at intervals of three or four days. According to four-hourly chart no rise of temperature occurred, except on the day following the one-half and one milligram doses, when the mouth temperature rose to 98.6° and 99.2° F.; but on two occasions prior to the administration of tuberculin a temperature of 99.2° had been recorded. The local reaction was slight. The patient's weight rose steadily and later he was discharged. Fifteen months later he was admitted with decided crepitations in the right apex and tubercle bacilli in the sputum. Again the test was applied on four successive occasions with intervals of about seven days, followed by no increase of temperature, except on two occasions, 99° being recorded on the third day after the one-half and five milligram doses; but a temperature of 99° had been recorded a short time prior to the injections. Case 2.—The patient, a male aged 2, was admitted suffering from spinal caries and healed tuberculous abscesses on the foot. He received ¼, ½, and 1 milligram of tuberculin (T.), the highest subsequent temperature being 98.6° F. Five months later an abscess formed on the dorsum of the foot, broke down, and remained open for some time. In this case the maximum dose administered was 1 milligram, but the child was only 2 years of age. In this connection it is interesting to note that of the animals infected with human tubercle bacilli and tested with homologous tuberculin the following gave a temperature reaction (rises of 0.9° C. over the normal); 107 of 124 calves, or 86.3 per cent.; 6 of 6 goats, or 100 per cent.; 10 of 11 pigs, or 90.9 per cent., and 4 of 4 horses, or 100 per cent. Evidently neither in man nor in animals does the absence of a temperature reaction following tuberculin exclude active tuberculosis.

8. Meralgia Paræsthetica.—W. J. Rutherford describes this condition as one characterized by mononeuritis of the external cutaneous nerve of the thigh, and of infrequent occurrence. Rutherford thinks that it is not so rare as has been previously considered, since he has seen about a dozen cases in the last ten years, five cases in soldiers having come under his care within the last nine months. The condition is of importance from the military point of view, because it is capable of giving rise to disability of longer or shorter duration and may be recurrent. The condition, which may occur in both sexes, may be of bilateral symmetry, but usually one limb is affected. Sensation over the area of distribution of the affected nerve, which as a rule can be strictly delimited, is lost so far as finer sensibility is concerned, for slight touch, for perception of points, for heat and cold, and to a certain extent for pain, while deep pressure can be perceived and a touch on the bare skin is felt as though a layer of clothing intervened. In old-standing cases cutaneous thickening may be made out locally if a fold of skin is pinched up between finger and thumb, and in some cases the skin of the affected area begins to grow bald from atrophy of hair follicles; while cutis anserina is lost locally, so that no goose-skin appears over the affected area, even though the other parts show this distinctly. Perverted sensations are present in the diseased area. Pain is often present and may be severe. The etiology seems to be unknown, but the condition may owe its origin to purely mechanical causes and be dependent on the local anatomical peculiarities associated with the course of the external cutaneous nerve. Cutting down on the nerve has been suggested but as yet not tried. Treatment seems to be of little avail. During an attack rest and such drugs as phenacetin are indicated, while purgatives should be given, as a loaded sigmoid may add pressure in the region of the plexus affecting the diseased area. Warm underclothing must be worn on all occasions, as these patients consider climatic conditions can precipitate an attack. The main feature of the condition is the unreliability of the symptoms and the likelihood of relapse.

3. Shell Shock and Its Treatment by Cerebrospinal

Galvanism.—Wilfrid Garton says that the term "shell shock" is made use of to describe two distinct conditions—one a severe type of traumatic neurasthenia, and the other bearing no resemblance to a neurasthenic condition but characterized by hysterical manifestations. It is for shell shock of the neurasthenic type only that cerebrospinal galvanism is of service as a treatment, for, its use being based on the assumption that neurasthenia is an organic disorder, there is no reason to expect favorable results to follow in a condition of functional disorder. The following symptoms are usually found in this type: Headache, always aggravated by the advent of thundery weather; insomnia, mental depression, loss of memory, nervousness, bad dreams, fatigue without exertion, tremors, wasting, and loss of appetite. Paralysis of limbs or groups of muscles and localized pains may be present. The resemblance between this condition and neurasthenia following severe illness is so striking that a similarity of origin is exceedingly probable. The coexistence of the majority of these symptoms appearing in a series of cases admits of but one explanation, and that is that they are the effect of a common cause—organic disorder of the central nervous system; and, as there is no gross lesion, this is probably a derangement of metabolism. The character and personality of the patient are greatly changed by this condition, and it is inconceivable that such alteration can take place independently of any structural damage or metabolic disturbance in the organism. A possible explanation of the appearance and persistence of the symptoms is that the violent concussions of the explosion produce a partial paralysis of the nervi nervorum. The interference of nutrition of the whole nervous system would prevent the restoration of the nervi nervorum to their normal activity, thus producing a vicious circle. Now, if there is any probability that shell shock of the neurasthenic type is due to a paralysis of the nerves regulating nutrition or a disorder of metabolism, then the use of the galvanic current is a treatment from which one has every reason to expect good results, for the most powerful agent we have for stimulating the nerves to activity is electricity. The apparatus used is a battery of wet Leclanché cells connected to a switchboard on which there are two other resistances, each of 1,000 ohms, one in series and one in parallel with patient and milliampèremeter. The treatment is commenced with no resistance in parallel and full resistance in series. If this apparatus cannot be obtained a battery of twelve dry cells, with cell collector and galvanometer and a resistance of at least 1,500 ohms, may be used. No current derived from the mains or any universal apparatus should ever be used for this treatment. A pad composed of about sixteen layers of lint, soaked in a solution of sodium salicylate in distilled water, is applied to the forehead, care being taken that the pad is evenly wetted and that its center coincides with the middle of the forehead. A metal plate connected with the negative pole is placed over the center of the pad and the whole bound firmly to the head. A similar pad soaked in tap water, covered with a metal plate connected with the positive pole, is firmly bandaged to the lumbar region. The current is turned on slowly, and for the first treatment Garton uses only 10 milliampères for ten minutes, and does not reach the full strength (20 milliampères) till the third or fourth treatment. The patients in the service whom Garton treated by this method did not remain under his care sufficiently long enough to effect a cure, but made rapid progress toward recovery. Several cases with improved results are cited, and Garton concludes that as a result of this method of treatment nearly all cases of neurasthenic type of shell shock would derive great benefit from it and the majority of cases, excepting those of the most severe type, would be cured in under three months.

Journal de Médicine de Paris.

September, 1916.

Indications for Purgatives in Diseases of the Liver.—Dufourt refers to Louis XIII and his 259 purgations in one year. This period was the zenith of the cathartic, for later scepticism became apparent and certain prominent individuals were thought to have purged themselves to death. But after a period of reaction the custom again gained ground, probably because venesection was being abandoned. Purgatives were believed as a class to stimulate the hepatic cell, to excite peristalsis, and, in general, to detoxicate and disinfect the body. Modern studies have shown that the first stools of purgation abound in microbian intestinal flora, and that on the next day these were reduced to 10 per cent. of the normal. Certain nitrogenous substances, however, like the sulphoethers and indican, have been shown to be innocent of the accusation of being concerned in intestinal putrefaction. In fact, when these substances have reached the urine they are in a state of complete oxidation and are not indexes of intestinal toxicity. Purgation is known to produce nervous depression which at times amounts to syncope; those thus affected may have not in the least been distressed by their constipation. Often but small eaters, they have been urged that there is peril in allowing ingesta to accumulate. Such patients are left prostrated and dejected. Even a spontaneous passage has been known to have the same results. A purge often makes a subject ill all over. He is thirsty, has no appetite, sometimes has mild chills, and subfebrile temperature. In any such case catharsis can hardly have been indicated. The author next takes up in great detail the view that purgatives unburden the liver, with the old conclusion that true cholagogues do not exist beyond all dispute. Not one has ever been proved to increase the secretion of bile, although not a few may perhaps promote excretion of that fluid. In primary icterus due to some deficiency in the function of the hepatic cell cholagogues are useless. On the other hand a flow of bile from the gall ducts only may be brought about even by milk purgatives. Disturbance of the liver is secondarily associated with digestive disorders and diarrhea may be in evidence as well as constipation. Hence the truth of the paradox the purgatives are indicated in diarrhea, while constipation may be overcome in other ways. This doctrine emanated originally from Trousseau and has been upheld by the experience of French colonists. In the tropics diseases of the liver, of such large incidence, are associated with diarrhea, which is treated by sulphates of soda and magnesia. Not every patient is benefited thus, and certain women suffer from purgation in the tropics no less than in the North and irrespective of the indications. Those who benefit chiefly are men, great eaters, often gouty, with distress over the liver, which as a matter of fact is congested or inflamed. Calomel relieves them mightily, although it does not purge them because a small dose is all that is necessary.

Death of a Sword Swallower.—According to Weinert, a reservist who could swallow his side-arm was shot through the chest, the wound healing completely. When he first resumed his sword swallowing, the point of the weapon encountered marked resistance, followed by fatal hemoptysis. The aorta had been perforated as a result of secondary displacement of the esophagus.—*Münchener medizinische Wochenschrift.*

Insurance Medicine.

Medical Selection for Life Insurance.—JOHN L. DAVIS, in presenting this subject before the Section on Life Insurance, State Medical Association of Texas, Galveston, said that life insurance companies are paying Texas examiners about a quarter of a million dollars a year in fees, and that these fees are always cash and never have to be earned twice, as often happens in the doctors' ordinary medical practice; therefore the subject should interest medical men. Life insurance companies are great instrumentalities for promoting thrift, unselfishness, and good citizenship, however, they are not primarily planned to be humanitarian institutions, but commercial enterprises. As such their first purpose is to pay dividends to stockholders. Their funds must be securely invested to earn at least the interest provided by the table on which premiums are based, and their chief profits come from savings in mortality, that is, from having a death loss less than that expected under the experience table; also from gains in interest over the 3½ per cent usually adopted as the company's permanent standard or reserve basis. This savings depends primarily on the care exercised by the medical examiners in the field. If this work is carefully and capably done, other things being equal, the mortality will be well within the tables, and in the newer companies the death losses will be far less than the legal amount set aside for this so that a very substantial balance will remain at the end of the year to be credited as surplus.

As is well known the medical examination covers several general features: the applicant's present physical condition and record of past illnesses; his habits, environments, family record, financial circumstances, etc. Much depends upon the keen medical insight of the examiner, as a physician with experience can tell from general observation of an applicant as to his physical condition. Habits of mental, moral and physical life are portrayed in the countenance and bearing of an individual; but in most cases the examination may proceed along the course provided in the examination blank. One point Davis emphasized, the applicant's attitude toward the examiner, which he states is very different from that of the sick man consulting his physician for relief. Then all details as to physical condition are most eagerly told, while the same individual when examined for life insurance assumes a different viewpoint, and compels the examiner to find out all details, past and present, for himself. The examiner must always allow for the existence of a duplex personality like Dr. Jekyl and Mr. Hyde. Davis offers a few general suggestions as to medical selection: first, the physical build. The standard man at 35 years of age is about 5 ft. 9 in. and weighs 165 pounds; for every inch above or below there is to be added or deducted about 5 pounds. As he grows older the weight slowly increases about half a pound a year. But actual insurance experience has shown that mortality among those under 40 is less among individuals rather heavier than the standard; after middle life the reverse is true, "light weight" old folks live longer. When the abdominal girth is larger than the fully expanded chest, mortality is noticeably increased. Alcohol and its use has both a direct and indirect bearing, for it has exacted a heavy toll from life insurance companies. Anstie's limit, two ounces of alcohol daily, seems to be more than can be ingested day after day without material damage. Reformed drinkers, like many other reformers, are short lived; their mortality is from 50 to 75 per cent. too high for life insurance. These facts should emphasize the need of thorough inquiry into the man's habits, past and present. Another point is that every illness leaves its impress on the body, and while most of these impairments and scars cannot be detected, they are there, nevertheless, and shorten life. A list of diseases which have affected life, though recovery at the time and apparent health was attained, is given by Davis. He includes asthma, albuminuria, bilious colic, gallstones, gout, alcoholic habits, pulse, pleurisy, rheumatism, and syphilis. Regarding heredity, it is well recognized that certain families are long lived; others lack resistance and die early of ordinary diseases. Family resistance to disease is therefore essential in valuing a risk. The inherited proclivity for certain diseases as well as inherited individual habits and traits of temperament are all to be considered as having a bearing on the applicant in question. However, in estimating the weight of hereditary influence one must be broad and equitable, not confining inquiries exclusively to unfavorable features transmitted, for ancestors confer on us not only impairments, but even more positively a tendency to vitality and health, otherwise nature's purpose to perpetuate the race would be rendered futile.

Finally the examiner should have in mind the differing mortality from a given disease at different ages. The serious diseases of young manhood are those of germ origin—as consumption and typhoid fever; they are most common and most disastrous before middle life; after middle age, the death losses come chiefly from degenerative diseases. When examination is completed and careful inspection has been made of the work done and applicant has been given his rating, the examiner should put himself in the place of the medical director and see if all facts are clearly and fully set forth. Sometimes such a review will show the need of further explanation on the part of the examiner. This work is akin to that of a title examiner in real estate, except that this is an inquiry into a title of health. On the recommendation of the examiner a deed is given involving possibly thousands of dollars. Fortunately the grave responsibility placed upon examiners has rarely been misplaced. Davis states that after nearly thirty years of close acquaintance with medical examiners almost from coast to coast, he desired to affirm that for dependability under all circumstances, for efficiency and character, medical examiners rank among nature's noblemen.—*Texas State Journal of Medicine.*

Concealment of Newly Discovered Disease.—The Arkansas Supreme Court holds that, where an insured, after applying for life insurance in one company, but before receiving the policy was told by another examining physician that he had Bright's disease, and he told the physician to make a microscopical examination, which confirmed the diagnosis, and he then arranged for treatment in the city to which he was about to go, his failure to disclose his condition to the first insurer was an intentional concealment of a material fact, which voided the policy.—United States Annuity & Life Ins. Co. v. Peak, 182 S.W. 565.

Book Reviews.

MEDICAL RECORD VISITING LIST AND PHYSICIANS' DIARY FOR 1917. Dated and undated. Newly revised. Price, $1.25 to $4.00. New York: William Wood and Company.

THIS well known visiting list is issued betimes, and, as heretofore, it is compact and useful. It contains the customary visiting list, with special blanks for consultation practice, obstetric engagements and practice, vaccinations, register of deaths, addresses of nurses and patients, and cash account. There is much miscellaneous information at the beginning of the volume. The visiting list has long enjoyed a well deserved popularity, not only on account of its excellent arrangement, but also because it is of convenient size and is handsomely bound.

THE PRACTITIONER'S VISITING LIST, 1917. For Thirty Patients per Week. Price, $1.25. Philadelphia and New York: Lea & Febiger.

THIS popular visiting list contains the usual blank pages for noting the daily calls and charges for the same. The text portion contains a scheme of dentition; tables of weights and measures and comparative scales; instructions for examining the urine; diagnostic table of eruptive fevers; incompatibles, poisons and antidotes; directions for effecting artificial respiration; extensive table of doses; an alphabetical table of diseases and their remedies, and directions for ligation of arteries, etc.

THE PHYSICIAN'S VISITING LIST (Lindsay & Blakiston's) for 1917. Price, $1.25. Philadelphia: P. Blakiston's Son & Co.

THIS is the sixty-sixth year of publication of this useful visiting list. Some new tables have been added, the most useful of which would have been one of the isolation periods in infectious diseases had it been more complete. The dose list has been revised to conform with the new edition of the United States Pharmacopœia. This table would have been more useful had the official drugs been designated and had synonyms been noted; acetanilide, for instance, is given (dose 3 grains), and also antifebrin (dose 5 grains), with nothing to indicate that they are the same drug; similarly acetphenetidin and phenacetin are listed with no hint as to their identity.

CHRISTIANITY AND SEX PROBLEMS. By HUGH NORTHCOTE, M. A. Second edition, revised and enlarged. Price, $3 net. Philadelphia: F. A. Davis Company, 1916.

THIS book is obviously a sincere, if somewhat confused attempt to present sex problems and a solution of them. In its second edition it is enlarged by many references to recent literature on the subject, especially to the writings of Havelock Ellis and Iwan Bloch. The presentation of the problems is as a rule fairly adequate, but his solutions do not seem so convincing. He offers nothing new or beyond the usually presented advice and always emphasizes his belief in the efficacy of religion as a curative agent. The work is confused and inadequate and yet it will serve its purpose to a certain extent. It has often seemed that much of the difficulty from sex problems that vexes us at the present time arises from the fact that we are in a transition period between prudishness and frankness and that our chief sin is hypocrisy. If this is true, any sincere publication aids in the accomplishment of frankness and therefore does good service.

PRACTICAL MASSAGE AND CORRECTIVE EXERCISES. By HARTVIG NISSEN, President of Possee Normal School of Gymnastics; Superintendent of Hospital Clinics in Massage and Medical Gymnastics; for twenty-four years Lecturer and Instructor of Massage and Swedish Gymnastics at Harvard University Summer School, etc. Revised and enlarged edition of the Author's "Practical Massage in Twenty Lessons," with many additions. With 68 original illustrations, including several full-page half-tone plates. Price, $1.50 net. Philadelphia: F. A. Davis Company, 1916.

MR. HARTVIG NISSEN has won a well deserved reputation in this country as an exceptionally able teacher and exponent of the principles and practice of massage and corrective exercises. He thoroughly understands the theory as well as the practice, and is therefore peculiarly competent to write a book on the subject. The book is well worthy of the author's fame and may be commended to the attention of all those who desire to gain a good working knowledge of mechanotherapy.

DISEASES OF THE DIGESTIVE TRACT AND THEIR TREATMENT. By A. EVERETT AUSTIN, A.M., M.D., Former Professor of Physiological Chemistry at Tufts College, University of Virginia, and University of Texas; present Assistant Professor of Chemical Medicine, in charge of Dietetics and Gastrointestinal Diseases, Tufts College; Member of American Gastroenterological Association and American Society of Biological Chemists; Physician to Mt. Sinai Hospital and Berkeley Infirmary, and Assistant to Boston Dispensary; Author of "Manual of Clinical Chemistry," etc. With eighty-five illustrations, including ten color plates. Price, $5.50. St. Louis: C. V. Mosby Company, 1916.

PERHAPS 50 per cent of all patients appearing at a medical clinic complain of "stomach trouble." The percentage in office practice would at least be high. "Stomach trouble" may mean any of the "Diseases of the Digestive Tract" of which Dr. Austin's book treats. Hence the physician should be well versed in the symptoms and methods of diagnosis as well as effective methods of treatment. Dr. Austin aims to meet this need in covering carefully, though in not too great detail, the various diseased conditions which may arise in the stomach and intestine. The book is rather conversational in style. In the parts on analysis of gastric contents and feces this is objectionable as the descriptions of chemical methods are not given in a detail or with a clearness which would be necessary for anyone not already acquainted with the methods used. It is surprising that there is no discussion of the fractional study of gastric digestion as worked out by Rehfuss and his associates. There are two excellent chapters on dietetics and treatment of digestive disorders. Therapeutic values of various foods with reasons for such values are given and numerous suggestions which only a person of wide experience could offer. A continuous study of the food value and chemical value for the special condition to be treated is evident. There is a careful study of those foods which stimulate gastric secretion and hence should not be used in hypersecretion. There are satisfactory discussions of the milk, vegetarian, and salt-free diets and a good section on hydrotherapy in such simple forms as may be carried out by any patient at home. Massage is discussed, but one is surprised to find no place given to active exercises of the abdominal muscles, from which such excellent results may be obtained.

THE DACK FAMILY. A Study in Hereditary Lack of Emotional Control. By MRS. ANNA WENDT FINLAYSON, Field Worker of Warren State Hospital, Warren, Pa. With Preface by CHARLES B. DAVENPORT. Price, 15 cents. Eugenics Record Office. Bulletin No. 15. Cold Spring Harbor, N. Y., May, 1916.

THIS is a very excellent report of a very careful study. The study has been undertaken in a truly scientific manner and the material handled scientifically. The difficulties which Mrs. Finlayson has surmounted can be imagined, for this report involves successful, tactful interviewing of a large number of individuals. That there are numerous other families of which similar studies would be valuable, there can be no doubt, and it is to be hoped that others doing such work may be as well fitted for it as Mrs. Finlayson.

THE EXPECTANT MOTHER. By SAMUEL WYLLIS BANDLER, M.D., Professor of Gynecology in the New York Post-Graduate Medical School and Hospital. Illustrated. Price, $1.25. Philadelphia and London: W. B. Saunders Company, 1916.

DR. BANDLER'S book is a strange mixture of information to the mother and information to the physician. In fact, at the end one is left in doubt whether it is written for lay readers or for his own profession. Too dogmatic statements of what should be done during delivery are scarcely wise in a book written for the laity. Many obstetricians would not agree with Dr. Bandler that repeated vaginal examinations are either necessary or advisable. And his suggestion of the use of fituition to establish labor or quicken it during the dilatation of the cervix, is scarcely the accepted stand. On the other hand, the book gives much information that the intelligent mother would understand. The discussion of the activities and overactivities of the ductless glands comes under this head, and also those on eugenics and puberty.

Society Reports.

JOINT MEETING OF THE NEW ENGLAND PEDIATRIC SOCIETY, THE PEDIATRIC SECTION OF THE NEW YORK ACADEMY OF MEDICINE, THE NEW YORK STATE PEDIATRIC SOCIETY, THE NEW JERSEY PEDIATRIC SOCIETY, AND THE PHILADELPHIA PEDIATRIC SOCIETY.

Held in Boston, November 4, 1916.

DR. ALEXANDER C. EASTMAN, PRESIDENT OF THE NEW ENGLAND PEDIATRIC SOCIETY, IN THE CHAIR.

A Clinical Day.—As is usual on these occasions the day was spent in visiting various institutions and attending clinics. In the morning members of the societies met at the Harvard Club, which was the headquarters for the day, and from here were taken to visit the following institutions: The Massachusetts General Hospital, where Dr. Fritz B. Talbot spoke on "Problems in Metabolism"; the Boston Dispensary, where Dr. Maynard Ladd discussed "Clinical Cases with Special Reference to Feeding"; the New England Home for Little Wanderers, where Dr. W. R. P. Emerson spoke on the "Problem of the Delicate Child"; the Children's Hospital, at which Dr. John Lovett Morse gave a clinic; the Infants' Hospital, where Dr. Charles Hunter Dunn, Dr. Howell and Dr. Grover demonstrated their method of giving intrasinus injections, and the Baby Hygiene Association, which conducts 13 infant welfare stations and is doing a work entirely preventive and educational. Luncheon was served at the Harvard Medical School and in the afternoon a visit was made to the Massachusetts School for the Feeble-minded at Waltham. Here a clinic was given by Dr. Walter E. Fernald, superintendent of the school.

Evening Session.

Medico-educational Problems in the Treatment of Atypical Children.—Dr. G. HUDSON MAKUEN of Philadelphia read this paper, in which he said that the physician was beginning to realize more and more the importance of treating his patients rather than their diseases, and therefore in his preparation for the practice of medicine he was finding it necessary to study psyhcology as well as physiology, anatomy and chemistry. This was the result of a fuller realization of the fact that there was something which distinguished the human organism from a mere laboratory receptacle or test tube, and this something was obviously the mind or personality of the individual. The close relationship between mind and matter was now generally recognized and we knew that the physical organism of man was the basis of his psychical development. It was well known that the inefficiency of adult life was largely due to the mistakes of childhood, but it was not so well known that many of the actual diseases of later years might be traced to faulty habits acquired during infancy and adolescence. Children were largely what we made them, and the factors that determined their psychophysical condition as well as their personality were heredity and environment. Heredity was an important factor in the development of children, but environment was even more important and it was always subject to change and improvement, and in addition to this it was probably even more responsible than heredity for putting the prefix "a" in atypical as it related to children. Thus the most important feature in the child's environment was his education and training, and the most important and neglected period in the life of any individual was that which came prior to the so-called school age. Teachers claimed that the failures of their pupils were due chiefly to faulty habits formed before their entrance into the schools and colleges. The so-called fixed habits were the early ones formed during the child's physical and mental development in the first years of his existence. The Jesuits had a saying, "Give me the first seven years of a child's life and I care not who has the rest of it." While the mind of a child had a physical basis, yet his mental activities determine to a great extent the character of this basis by regulating its development, and hence it was that the general physical condition of the child might be influenced for good or ill by the character of his mental and emotional activities. Medico-educational methods become real measures of prevention only when they began to be employed during infancy. Medico-educational methods should aim, not to remake the child, but to make the "absolute best" of what had already been made. Nervousness was the most characteristic malady of children and its treatment should be, first, preventive, and, second, curative. Preventive treatment was applicable in the earliest infancy and consisted largely in an attempt to control the child's physical activities through a careful direction of his psychical and emotional activities. If the child was normal physically, this treatment should result in the development of normal physical and emotional faculties, but if the child inherited physical abnormalities, such as cleft palate or other irregularities of structure, surgery or some form of medication might be indicated in addition to the psychophysical training. Punishment should never be necessary except perhaps at the very beginning and before the child was mentally susceptible to medico-educational measures. It was estimated that there were upwards of 300,000 stammerers in the United States alone and, in the speaker's opinion, if this vast army of defectives could have had the right kind of early training there would now be few if any stammerers to contend with, and what was true of stammering was true of similar and allied nervous diseases. The remedial and curative treatment of atypical children was an effort to improve their conditions through their physical activities. The personality of the child was modified and molded through what had been called the reflex influences of its own acts and expressions. To make any act or gesture or mode of speech or motion habitual through deliberate repetition was to stimulate in the personality the appropriate moral quality or emotion of which such an act or gesture was the expression. The Japanese had a theory that for one to be what he would like to be it was only necessary for him to persistently act the part. Doing things with purposeful intent was found to have a greater educational value than doing them carelessly or even in play. The play instinct was an important factor in child development, but it was at the present time the most overworked of them all both in the homes and in the primary schools. What might be called the work instinct was equally important and was now being greatly neglected in the early training of children. The difference between work and play should be clearly understood by the child, and the greater dignity of the latter should be impressed upon him at at early age. The child should be taught to do things not because they were easy, but because they were right, and the greater the difficulty of doing them the greater the educational value. Moreover work and play should not be commingled; they should form two distinct factors in education. Mr. Roosevelt's advice was sound; he said, "When you play, play hard, and when you work, don't play at all." The teaching of correct postural attitudes and good respiratory, phonatory and articulatory habits should have a conspicuous place in all medico-educational methods, both because of their esthetic value and because they tended to give to the individual greater self-respect, self-reliance and self-control.

Intestinal Venous Stasis; Diffusion of Bacteria and Other Colloids.—Dr. FENTON B. TURCK of New York read this paper and gave an exhibition of lantern slides showing the diffusion of bacteria through the intestinal wall. He stated that our ideas of medicine founded upon a morphological or static conception of the living body was being shifted more to the consideration of dynamic properties of life. Synthesis of organic compounds and the rôle of physics of colloids in biology had created a new concept of normal and abnormal conditions of the body. The membrane filter, itself colloidal in character, determined the rate of diffusion of the colloidal suspension that filtered through it. Different factors were involved in the permeability of membranes in the living organism. In the study of the phenomena the passage of colloids, such as the white of an egg, unchanged through animal membrane was surrounded by considerable difficulty because of the obscurity involved in the identification of colloid substances after filtration. The writer had found that emulsion of bacteria, such as the color bacilli, injected into the intestines of a fetal animal and living animals, would rapidly diffuse through membranes and tissues. By appropriate staining methods the rate of diffusion and the route by which diffusion occurred could easily be studied. Previous experiments of the author indicated that the intestinal tube was permeable to the intestinal flora. The degree of this invasion was great-

ly influenced by the splanchnic circulation, which altered the character of the intestinal wall and rendered it permeable to all forms of bacteria. When bacteria were injected into the intestines of the fetus distinct routes were taken from any depot along the entire tube. Microorganisms injected into the intestines of a fetal animal rapidly diffused through the mucous wall of the intestine, between the glands into the areolar tissue and then coursed along the wall of the intestines between the muscle coat and the mucous membrane. At this point many of the microorganisms underwent bacteriolysis. In the newborn there was no barrier, no arrest of passage by the mucosa labyrinth; a wall impervious to bacteria had not yet been sufficiently formed there, nor apparently were antibodies adequately generated, since as yet they had not been needed. As the body grew the tissues became less porous to bacteria. When disturbance of the splanchnic circulation and muscular atony of the wall of the alimentary tract were produced, then a reversion to the fetal state of the intestine followed, and then the body needed to be protected from the "toxins" formed in the "zona transformans" and anti-anaphylaxis was, it might be said, automatically established. The passage of the bacteria took place from the intestinal tract into the intestinal wall between epithelial cells and not through or into the cells and between the muscle cells of the muscular mucosa. As rapid bacteriolyses were seen to take place in this submucous zone, Dr. Turck said he had named it the "zona transformans." The degree of permeability of the intestinal wall in a living subject was increased by a number of factors, namely, (1) Mechanical obstruction of the intestines; (2) an interruption of the circulation sufficient to cause atony; (3) an interference with the nerve supply; (4) a number of pathological conditions. In order to induce permeability fundamental changes in the flora of the individual and in the physiology of the organ must be induced; among the means of bringing this about were thirst, hunger, overfeeding, and shock. Dr. Turck described his experiments with these various factors which supported his proposition that bacteria passed readily through the mucous membrane into the submucous tissue, where they underwent bacteriolysis and created lesions of a non-inflammatory character. Autolysis of the tissues took place following venous stasis with a resulting asphyxia of the cells. The muscle cells underwent the characteristic changes of Zenker's degeneration with atony and dilatation. Feeding experiments by which various lesions, such as ulcers of the stomach and duodenum were produced, were described, and also experiments showing the results of ligatures applied to the intestines at different levels. Ligations of the lower portion of the intestinal tract were not so evident in causing bacterial migration as in the upper segments. No bacteria seemed to enter the blood or lymph vessels. The feeding experiments further showed that fat and fatty acid increased the diffusion rate of the intestinal bacteria through the intestinal wall and hastened the fatal termination. Six monkeys fed with small squares of bread fried for thirty minutes in cottonseed oil, in addition to the usual vegetable feeding, died in from three to six weeks and showed an increase in the filtration of bacteria in the tissues. Lesions resulting from disturbances produced in the upper intestinal tract were shown to be more quickly fatal than those made in the lower intestinal segments. The passage of the living bacteria into the tissues caused a reduction (by absorption) of the protective bodies (antiferments), and resulted in autolysis. A study of the clinical picture as seen in the human being paralleled these findings. Stasis, induced by frequent feeding, causing precipitation and delayed digestion and resulted in fractional digestion and the production of fatty acids. The changes produced in the cells were not due to lack of oxygen or increased carbon dioxide but were due to acidosis, the result of fatigue to the muscle cells and asphyxia of those cells from venous stasis. This resulted in atony and permeability of the muscle wall with diffusion of bacteria and of the fractional protein products. Following bacteriolysis and proteolysis, anaphylaxis ensued or, in other words, a condition of acidosis. The symptoms of this condition in its acute form were shock, distention, prostration, convulsions, etc. The symptoms of the chronic condition were wasting, marasmus, anemia, etc. Treatment must have for its object the reduction of fatigue of the hollow muscle, prevention of fatty acid intoxication, intestinal retention and absorption of intestinal floral; it must also correct the acidosis, reduce venous stasis, increase immunity and maintain nourishment. Thus in the acute cases, gastric and colonic lavage; lavage with weak nitrate of silver, followed by sodium bicarbonate; demulcents and venesection, followed by infusion of sodium carbonate solution, were indicated. In extreme cases the transfusion of autoserum might be indicated and also the continuous bath. In the moderate and chronic cases, gastric lavage and colonic lavage, with gentle pneumatic gymnastics, were indicated together with demulcents, oil of cloves, and vaccines. The food should be reduced to the minimum fineness of particles; the interval between meals should be prolonged to the maximum point within the caloric safety, and regular feeding periods should be established to conform to the curve of muscle work and relaxation. Foods rich in mineral salts should be provided, as vegetables steamed and made into a purée. The intake of fat should be reduced to a minimum; heated and stale fat should be prohibited. No extractives were allowed, though in older children one might give extract-free meat. For a time the total protein intake might be reduced. The medication consisted of alkalies by the stomach and an analgesic mixture. The object of the demulcent, such as Irish moss or liquid vaseline, was to prevent the passage of bacteria through the intestinal wall. Adsorption of the bacteria might be favored by the administration of Fuller's earth, charcoal, or very fine bran. If laxatives were required, phenolphthalein and calomel might be given.

The Epidemiology of Bacillary Dysentery.—Dr. W. G. SMILLIE of Boston presented this paper. He stated that their study had been made in connection with the work of the Floating Hospital. The need of such a study was evident from the fact that the incidence of bacillary dysentery was greater than that of more feared and more widely advertised children's disease, as poliomyelitis, and among children the death rate was equally high. The methods of treatment of bacillary dysentery had long been known, but the mode of transmission of the disease had excited only indifferent or random speculation. The conditions furnished by the Floating Hospital were most favorable to a study of the transmission of bacillary dysentery because of the fact that the victims were usually infants under fifteen months of age, whose activities were limited and who therefore came into contact with comparatively few people and ate but few articles of food. It was comparatively easy to trace the source of infection in a baby under one year of age, but after the child could walk it became most difficult. Other conditions favoring a study of the epidemiology of bacillary dysentery were the fact that the diagnosis was clear cut. There was a definite clinical history; the dysentery bacillus could be isolated from the stools, and specific agglutinins were developed in the blood of the patient. This furnished a good working basis for investigation. The fact that the bacillus was found in the feces only and not in the other secretions of the body made it evident that every case represented some short path between the infected feces of the patient and the mouth of the victim. The incubation period of adult dysentery was from three to seven days. The disease in infants was one with a summer incidence, being most prevalent in July, August and September, and, finally, bacillary dysentery had a preference for the children of the poor. In addition to the above knowledge they had records of all cases that occurred and were reported to the city boards of health, thus bringing out nests of infection in all parts of the city. A spot map was made of all the cases of last year for purposes of comparison with the centers of infection this year. A record was kept of the daily maximum and mean temperature and of the relative humidity for the whole summer, of the nationality of the parents, housing and individual home conditions with reference to sanitation, together with careful investigation of all the activities of the case for a period of two days before symptoms of the disease developed. In all, 79 cases were studied, 49 being house cases, and 26 related cases discovered in the course of the investigation. While 75 cases were obviously insufficient as a basis for drawing definite conclusions as to the influence of temperature and humidity there seemed in this series of cases to be no relation between high temperature, high relative humidity and the case incidence. The case incidence seemed to be more closely related to the incidence of flies rather than temperature, for the hot weather was almost over before there were many cases of the disease and reports of new cases continued to come in well through September,

though the humid weather had passed. The families chiefly afflicted were not the illiterate foreigners, but the neglectful, poorer class American family. This was not attributable to the fact that the foreigners were more cleanly, sanitary or intelligent than American parents, for in truth they were very much less so. It seemed to be due to the fact that most foreigners nursed their infants. Only one of the cases occurred in a nursing baby, and this child was nursed only during the night and was fed with condensed milk mixtures during the day. Though bacillary dysentery was ordinarily a disease of poverty and filth, these were not necessary accompaniments, for the disease might be found in the better portions of the city. For estimating the relation between bacillary dysentery and housing conditions a score card was devised somewhat similar to that used for scoring dairies. In all forty-one homes were scored; the highest score was 94 per cent. and the lowest 15 per cent. The average score for those cases of bacillary dysentery that were due to direct contact was only 48 per cent. The average score of those cases that were a source of infection to others was 41 per cent. The average score of those cases due to infection from food was 59 per cent., and the average for those cases for which no source of infection was found was 71 per cent. The summary of the sources of infection was as follows: Contact with an acute case, twenty-one cases; contact with a carrier, two cases; contact with a house case, four cases; condensed milk epidemic, fifteen cases; ice cream cones, nine cases; flies, six cases; source of infection unknown, fifteen cases; milk, water, and fruit, each one case. An important fact with reference to the contact cases was that many of these cases were in the older members of the family, and in these individuals the disease showed itself in a mild form. Undoubtedly many cases of summer "ptomaine poisoning" were truly bacillary dysentery and, though these sporadic cases were not in themselves serious, they might become a great menace to the community, and particularly to the babies of the community; for, as this investigation showed, a mild adult case might readily infect a baby, with fatal results. As a general rule, it might be stated that in every dirty, careless house which the speaker inspected, and in which the sick child remained for more than one week, there resulted a contact case. There was evidence to show that four babies developed bacillary dysentery in the hospital wards, for each child was admitted with quite a different diagnosis and did not develop the disease until seven to ten days after admission. These were the only contact cases that occurred in the hospital, though virulent bacillary dysentery cases were on board all summer. Since extraordinary care must be exercised to prevent cross-infection, no child with bacillary dysentery should be admitted to a hospital unless all facilities for isolating these cases are provided; the most rigid precautions were necessary, and particularly fly exclusion. A number of the cases cited showed very conclusively that the fly was to blame for carrying the infection. The tenement mother was usually careless to protect her infant's stools from flies, and the diapers were seldom boiled; and since flies were so abundant and screens almost unknown, it was most extraordinary that more cases were not transmitted in this way. It seemed more than probable that some of the fifteen cases that had been tabulated as of unknown source were due to flies. There was a Shiga epidemic last summer that gave an excellent example of the various modes of spread of the "casual case" of dysentery. In this instance the epidemic originated with the two-year-old son of the dairyman in Haverhill. The source of this infection was probably an ice cream cone eaten in Lawrence. The father, mother, and one other child developed diarrhea; the father, being only moderately prostrated, kept on with his work in the dairy. The milk of this dairy was sold almost exclusively to the Deaconess' Home, a fresh air farm for children between the ages of seven and fourteen years. In this institution there developed about twenty cases out of a total of seventy children. This epidemic began on July 22, and on July 27 the children were all sent to their homes. One of these children went to Pine Heights, Dedham, became seriously ill, and after five days was taken to the hospital. This child's brother and two sisters also became ill with the same kind of infection. The dejecta of these children was thrown into an open privy without disinfection. A neighbor who came in to assist in the care of these children carried the infection home to her husband. Within a few days a child living across the street developed bloody dysentery and died within a few days. About the same time three adult members of one family living about 100 yards away developed severe dysentery, which persisted for a few days only. The evidence seemed to point to flies as the carriers in these last two families. A case developed in the house adjoining that in which the first child, the one coming from the Deaconess' Home, lived. The fifteen cases in which the source of infection was traced to condensed milk were interesting. They occurred in widely separated localities, but in each instance the evidence pointed very definitely to a particular batch of a certain brand of condensed milk.

Dr. Henry I. Bowditch congratulated Dr. Smillie on the work he had accomplished and the results he had attained. He said it might be of interest to hear the results of their study of the bacillary cases during the past three summers, since they were especially interested in dysenteries. In 1914 there were seventy-nine cases that came under their observation, of which 68 per cent. gave a positive Flexner organism; in 1915 there were seventy-five cases, 85 per cent. of which showed the Flexner infection; in 1916 there were sixty-four cases (Dr. Smillie had a few additional ones), and of these 88 per cent. showed the Flexner infection. In three-fourths of these cases the bacteria were recovered from the stools and in others at autopsy, and in a certain few the diagnosis was made by finding the agglutinins. At the same time they had constantly tried to see how much of a factor the gas bacillus or the *B. welchii* was in these dysenteries. The *B. welchii* was found not to play an important part. It disappeared quickly in the early course of the illness, and was frequently seen to appear later when other foods were given. In 1914 a closer investigation than usual of the *B. welchii* was made, which resulted in finding it in 11 per cent. of infectious conditions, in 27 per cent. of digestive disturbances, in 28 per cent. of malnutrition cases, and in 28 per cent. of normal cases. The infectious cases were studied closely, while the other cases were picked at random. They felt at present that the Flexner organism was the main etiological factor; that the gas bacillus was a complicating factor, but not the main etiological factor. This was different from the stand taken some years ago. On the Floating Hospital, when a case entered with the clinical picture of dysentery the mode of treatment carried out was to keep the child on water for the first twelve hours and then place it on a food with a high percentage of carbohydrate, and moderate protein, as, for instance, fat 0, sugar 12 per cent., and protein 6 per cent.; this food was usually given in the form of a fat-free milk with sugar added. This was continued if the gas bacilli were not present; but when the gas bacilli did occur the carbohydrates were diminished.

AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.

Twenty-Sixth Annual Meeting—Held in New York City, September 12, 13, and 14, 1916.

The President, Dr. Jefferson D. Gibson of Denver, in the Chair.

President's Address: Some Speculations for the Future.—Dr. Gibson stated that by the plan of treatment which he advocated the death rate from tuberculosis could probably be made in eight years less in the United States than the present death rate from smallpox. He outlined his plan as follows: Make use of the health boards of every city and county. Every child in the public or other school should be examined for tuberculosis and treated, if needed, under the direction of the board of health. The health board or commissioners should set aside and maintain a department for this special school work, known as the Tuberculous Department, and the chief or manager of this department and all assistants needed should devote their entire time to the care, examination and treatment of the school children. Every child that is tuberculous, or shows a reaction or any sign of tuberculosis, should be treated, in addition to the ordinary hygienic and dietic measures, by the *x*-ray for its direct effect on the bacilli and the lung tissue by static electricity, for its direct effect upon the heart, nervous condition, and general metabolism; and by inhalations of an ozonized oil nebula for its effect on the cough. By this method during the past

year he had been able to save from death 92 per cent of all applicants, of all stages and complications of pulmonary and other forms of tuberculosis. Tuberculosis in young children was usually glandular, and most latent or incipient tuberculosis in children was in the bronchial, mediastinal, cervical, abdominal, or inguinal glands. It was in this stage that the disease should be detected, because it was well known that the *x*-rays would cure a tuberculous gland.

The Treatment of Hypertension and Complicating Conditions.—Dr. WILLIAM BENHAM SNOW of New York said he viewed hypertension as secondary only to a toxic cause, and as the actual cause of the resulting arteriosclerosis. If the tension was relieved the labor of the heart would be relieved and the arterial degeneration to a degree arrested. In the treatment the most important factor was the regulation of the diet. In advanced cases all proteins should be eliminated from the diet, and in all cases they should be reduced in amount. In addition to the regulation of the diet, the high frequency current should be employed, by the autocondensation method. The patient was given daily treatments until the pressure fell to normal or recurred to the same figure following each daily treatment. This would be the compensation point for the individual case. At that point a fixed tension would persist despite the treatment, and beyond that it would be impossible to lower the pressure. After finding that point the treatments were given just often enough to maintain the pressure approximately at that lowered point.

Contact in Electrotherapeutic Applications.—Dr. FRED H. MORSE of Boston said this was an important factor in electrotherapeutics. He considered the shapes and sizes of electrodes, the best materials to be used, etc. He described an electrode which had proved very successful in his hands, made of asbestos combined with flexible copper gauze, covered with linen and with a rubber backing.

Roentgenographic Diagnosis of Dental Infections in Systemic Diseases.—Dr. SINCLAIR TOUSEY of New York read this paper and showed numerous lantern slides. He drew the following conclusions: A putrescent mass in the pulp chamber of a tooth might exist for months or years because the walls of the cavity could not collapse and were incapable of throwing out granulations and eventually filling the cavity with healthy tissue, which was the natural process of curing an abscess in the soft tissues of the body. This putrescent mass might constantly poison the bony tissue surrounding the apical foramen sufficient to produce an effect clearly recognizable in a radiogram. This condition might be unknown to the patient, and sometimes not reveal itself to the usual tests applied by the dentist. From this long-existing source of infection secondary lesions and symptoms of the gravest and most diversified character might arise. The *x*-ray was to be depended upon to show whether or not the source of trouble was connected with the teeth or the pneumatic sinuses, and if so, whether the trouble was due to malposition and unnatural pressure or to infection. It would be a mistake to regard every case as due to the teeth.

The Treatment of Inoperable Carcinoma by Bipolar Ionization.—Dr. G. BETTON MASSEY of Philadelphia said that in this method the active needles were inserted just beyond the periphery of the growth, while the inactive, negative electrode was inserted in its center. As no material amount of current traversed the general body structures, the method could be pushed to the point of producing a boiling temperature in the larger growths, thus adding the valuable agency of heat to the devitalizing chemical action of the dispersed ions of zinc from the erosion of the zinc electrodes attached to the positive pole. This method was applicable to large growths when heavy currents were needed. In small growths the ionization alone was sufficient, applied in the unipolar method. Illustrative cases were reported.

Prompt Removal of Exudate from Trauma.—Dr. A. B. HIRSH of Philadelphia drew the following conclusions: Prevailing modes of removing exudate from the tissues after injury are altogether inefficient, therefore inadequate, and lead to needless invalidism through nonunion or deformity after fracture or other interference with function. Prompt removal of any excess of effused blood and lymph is necessary for union of broken bone or lacerated soft structures, leading to resumption of normal function. Mechanical modalities, largely electrical, alone can supply the deep molecular contraction of tissue required to force back into torn vessels their misplaced fluids, and where such extravasated material has had time to become organized to soften it sufficiently to bring about its absorption.

Contraindications to the Use of High-Frequency Currents.—Dr. FREDERIC DE KRAFT of New York gave as the contraindications to the use of the high frequency current all conditions where a tendency to hemorrhage existed, for instance, in cases of pulmonary tuberculosis with a history of recent hemorrhage or in those where bleeding had occurred recently in the pelvic organs, uterus, and ovaries. As it stimulated cell functions it was contraindicated in hyperthyroidism, Hodgkins' disease, leucemia, etc. It should not be used in cases of walled-in pus, tuberculous glands, or acute rheumatism. It was seldom wise to employ it during menstruation. In certain cases of obesity it increased the weight.

The Importance of Dieting in Medicine.—Dr. ANTHONY BASSLER of New York outlined the facts to be kept in mind in diets for diabetes, cardiac decompensations, nephritis, polyarthritis, gall-bladder disease, intestinal toxemias, and constipation.

The Condenser Discharge; Its Use in Diagnosis and Treatment.—Dr. FRANK B. GRANGER of Boston said that in this method of testing muscles a condenser of known capacity was charged from the main or from a battery to a constant voltage and was then discharged through a muscle. For muscle testing this method bade fair to supplant other methods, as we had an exact numerical equation, instead of vague terms, and thus the improvement of the patient could be determined readily and rapidly. In therapeutics more work must be done, more cases tabulated and compared, before we could assign it its place in therapeutics.

Uterine Fibroids.—Dr. MARY ARNOLD SNOW of New York, after discussing the frequency, cause, classification, diagnosis, structure, growth, site, and symptoms of uterine fibroids, advocated their treatment by the *x*-ray, preferably by the fractional dose method. The advantages of the *x*-ray treatment were: It left the reproductive system intact, though sterile, whereas the radical operation meant incalculable reflex shock to the system mentally and physically. The *x*-ray treatment was an ambulatory treatment. There was no danger from hemorrhage. The patient enjoyed her usual comfort. With proper precautions there should be no disturbance of the digestive system, as from the after effects of an anesthetic, and there should be freedom from danger to life. The lowest mortality from surgery was 3 to 5 per cent. There was no period of convalescence, and insanity never occurred. The symptoms of the induced menopause were less pronounced than those following an operation. The contraindications were: Such severe symptoms that the life of the patient would be endangered by waiting for results from the *x*-ray; pedunculated submucous fibroids; infectious gangrene or malignancy, or where the fibroid was associated with disease of the adnexa.

The Value of the Cooper Hewitt Quartz Lamp in the Treatment of Alopecia.—Dr. WILLIAM H. DIEFFENBACH of New York in this paper gave a verification of the claims of Dr. Franz Nagelschmidt of Berlin in the treatment of alopecia by means of the ultra-violet rays emitted from the quartz lamp. He showed lantern slides of numerous cases in his own experience and that of Nagelschmidt.

Subacromial Bursitis.—Dr. J. E. DEERING of Worcester, Mass., said the treatment of subacromial bursitis in the first stage consisted in the use of a rather long treatment with a high candle power lamp, followed by twenty minutes to half an hour of diathermy. Often four or five treatments would relieve and cure a case. Where there was tension in the bursa static sparks should be used, preceded by the high candle power lamp. In the second stage during the formation of adhesions one should use the high candle power lamp, fifteen or twenty minutes of diathermy, and fifteen or twenty minutes of static wave if that be well borne. Where contraction of adhesions had taken place diathermy might be omitted from the foregoing treatment.

Some Phases of Intestinal Stasis and Its Treatment by Physical Measures.—Dr. WILLIAM MARTIN of Atlantic City detailed the history of an interesting case of intestinal stasis treated and cured by a combination of diathermy, light treatment and vibration of the intervertebral spaces and the static wave and the slow sinusoidal currents.

The Treatment of Infantile Paralysis.—Dr. FRANK E. PECKHAM of Providence, R. I., reported three cases of infantile paralysis treated in the early stage by the

static wave current over the lumbar region of the spine, the 500 c.p. lamp over the affected muscles and over the lumbar spine, and later vibration and gymnastic exercises.

The Treatment of Infantile Paralysis Based on the Present Epidemic. — Dr. H. W. Freuenthal of New York said that no advance had been made in treatment in the acute stage further than in the fact that, in cases where anterior poliomyelitis was detected immediately, the disease had been checked and paralysis averted by the use of immunizing serums obtained from persons who had already had the disease. Treatment should be begun in the second week. Pain could be relieved by the warm bath or an electric light bath. The affected muscles should be treated with the sinusoidal current alternating with a combined galvanic and faradic current. Massage should be instituted the moment the acute inflammatory symptoms disappeared. Attention should also be given to a class of active and passive exercises before a mirror, having the patient concentrate his mind on the affected muscles.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

College of Physicians and Surgeons of Ontario.

Final Examination, November, 1915.

MEDICINE.

1. Endocarditis. Discuss the types, etiology, morbid anatomy, and clinical manifestations.
2. Cirrhosis of the liver. Enumerate varieties, and discuss the pathology, symptoms and treatment.
3. Diabetes mellitus. Describe the mode of onset and urinary findings, and discuss in detail your treatment.
4. Discuss the cause, and describe the prodromal symptoms, course, and treatment of a case of typhoid fever.
5. Discuss the etiology, and describe the lesions and mode of treatment of: Impetigo contagiosa, Herpes zoster, Alopecia areata.

SURGERY.

1. (*a*) What symptoms differentiate a malignant from a non-malignant tumor of the breast? (*b*) What course would you adopt in doubtful cases? (*c*) Describe the operation for complete removal of the breast.
2. (*a*) How is intussusception produced? (*b*) Give symptoms. (*c*) Give treatment.
3. (*a*) Describe a method for amputation in the middle of the forearm. (*b*) Enumerate the structures divided.
4. (*a*) Give the differential diagnosis between anal fissure, hemorrhoids and carcinoma of the rectum. (*b*) Give the treatment of each.
5. (*a*) Give the differential diagnosis between malignant disease of the esophageal and pyloric ends of the stomach. (*b*) Give treatment in each case.

OBSTETRICS AND GYNECOLOGY.

1. Give the management of a case of pregnancy up to the advent of labor, and also from the delivery of the placenta to the end of the puerperium, in a normal case.
2. Pains: Define the following:—True, false, weak, cutting, atonic, expulsive, after.
3. Forceps and pituitrin: What are the indications, and the contraindications, for the use of each?
4. A woman's abdomen is enlarged from the pelvis to the level of the umbilicus. Mention the conditions which may produce such an enlargement. How would you make a differential diagnosis of them?
5. Prolapsus uteri; give causes, symptoms, and treatment, operative, and non-operative.

ANSWERS.

MEDICINE.

1. Endocarditis.

Types:—I. Acute { Simple / Malignant or Ulcerative { Septic / Typhoid / Cardiac

II. Chronic.

The difference between simple and malignant endocarditis is probably one of degree rather than of kind.

Etiology: Simple endocarditis is associated with rheumatism or scarlet fever. Malignant endocarditis is also associated with rheumatism, scarlet fever, and also with pneumonia or septic processes. Micrococci are often found. Chronic endocarditis may follow an acute endocarditis, or may be the result of syphilis, old age, high arterial tension, gout.

Morbid Anatomy: In the simple form there will be found a cloudiness, followed by edematous thickening of the valvular endocardium; superficial erosions, and the formation of small granulations; deposits of layers of fibrin and corpuscles from the blood, the whole process resulting in the formation of small warty vegetations. These vegetations are most marked at a slight distance from the free borders of the valves—*i.e.* those parts which come into opposition during closure. In course of time they are transformed into fibrous tissue. According to Poynton and Paine the infective organisms are conveyed to the base of the valves by the capillaries, and thence pass to the subendothelial tissues by the minute nutrient channels in the valvular substance; others hold that the organisms are derived from the blood circulating over the surface of the valves. In the malignant form the initial changes are similar, but there are some important differences, inasmuch as ulcerations may completely replace the vegetations. The differences are: (1) The vegetations when present are larger and fungating. (2) The underlying tissues are necrotic and show loss of substance and round-celled infiltration. (3) They contain masses of micrococci, while in simple endocarditis the organisms are scanty. The two forms cannot be distinguished by the organisms producing them; either simple or malignant endocarditis may arise from a pyogenic infection. (4) When the vegetations become detached they form *septic* emboli, giving rise to metastatic abscesses. (5) The ulcerative process causes great destruction of the valves, and may even lead to perforation of the curtains. (6) The subsequent or permanent changes in the valves, if the patient survive, are much more marked. (7) If the vegetation touches the mural endocardium as it flaps to and fro, the part touched becomes affected by contact.

As regards the side of the heart most affected—*Congenital* endocarditis attacks the right side of the heart (but note that many congenital cardiac lesions are due not to endocarditis, but to developmental faults); simple endocarditis attacks the left only; the *malignant* attacks *both sides*, though the *left* is much more implicated than the right side.

The vegetations are upon that side of the valve opposed to the blood-stream—viz., at the aortic valve the vegetations project into the ventricle, at the mitral valve into the auricle.

As in pericarditis, the myocardium almost always shares in the inflammatory affection.

In *chronic* endocarditis, when not directly due to acute endocarditis, the changes are: Formation of small nodular prominences, with thickening of the valve. The vegetations are much firmer than in the acute disease. Formation of yellowish, opaque fatty patches. Great increase of fibrous tissue, which subsequently contracts, producing much deformity. The cusps become rigid, curled, and may cause great destruction to the onward flow of blood, and at the same time fail accurately to close together when required. Great narrowing of the valvular orifice. Shortening of the chordæ tendineæ and papillary muscles. Frequently fusion of the chordæ tendineæ (adhesions). Calcification of the fibrosed portion.—(Wheeler and Jack.)

Clinical Manifestations: "Simple Endocarditis.—The signs are extremely ill marked; possibly increased rapidity of pulse, dyspnea, precordial distress, etc., may attract attention to the heart. On examination some dilatation of the heart, from the accompanying myocarditis, may be found, and a *recently developed murmur* of a soft blowing or bellows-like character may be heard in the mitral or aortic areas. The commonest murmurs are those of mitral regurgitation (systolic), or mitral stenosis (presystolic).

"It should be remembered, however, that in most fevers the heart is somewhat dilated, and a murmur, *not due to endocarditis*, may be present. We must therefore be cautious in coming to a too rapid conclusion that a suddenly developed murmur is indicative of endocarditis. An important distinction is that the onset of endocarditis is usually accompanied by a smart rise in temperature above the previous level, while in hemic murmurs, or those due to simple dilatation, this is absent. A diastolic murmur in the aortic area is likely to be organic (aortic regurgitation).

"*Malignant Form.*—Three types may be distinguished —*The Septic Type* is characterized by the symptoms of

septic infection—viz., rigors, sweats, oscillating temperature, emaciation and metastic abscesses. The symptoms may continue for months. *The Typhoid Type* is characterized by irregular or intermittent temperature, looseness of the bowels, petechial rashes, and a rapid assumption of the typhoid state. Great difficulty may be experienced in distinguishing this form from typhoid fever or meningitis. *The Cardiac Type* is that in which symptoms of acute endocarditis, with fever of a septic type, appear in the course of a chronic valvular lesion. In some of these cases death is rapid; others may recover after a protracted illness.

"Along with these general symptoms there are usually definite cardiac signs—development of murmur, dilatation of the heart, cardiac irregularity, and so on. But the cardiac symptoms may be altogether latent, causing difficulty in diagnosis."—(Wheeler and Jack's *Handbook of Medicine.*)

2. Cirrhosis of Liver. *Varieties:* Portal, or atrophic or alcoholic; biliary or hypertrophic; also syphilitic or pericellular.

Pathology. In *atrophic cirrhosis* the liver may be very small, but is sometimes enormously enlarged. The latter condition may be caused by congestion or fatty changes. Generally, in the atrophic condition, the surface of the liver is rough and nodular. The connective tissue is increased in quantity, and the liver cells are destroyed (probably by the poison which causes the disease). The fibrous tissue in Glisson's capsule is increased, the portal circulation is obstructed, and later the bile ducts are obstructed and the hepatic cells become obliterated. In the *hypertrophic cirrhosis* the liver is always enlarged. The following table (from Wheeler and Jack) gives the important features of the morbid anatomy of the two varieties of cirrhosis, together with the differences:

PORTAL OR MULTILOBULAR CIRRHOSIS.	BILIARY OR UNILOBULAR CIRRHOSIS.
1. The bile-ducts are not involved, and jaundice is a late symptom.	1. The smaller bile-ducts are inflamed (cholangitis); jaundice is early and severe.
2. The new-formed connective tissue compresses the branches of the portal vein.	2. The portal circulation is not impeded.
3. In the earlier stages, active congestion and proliferation of connective tissue in the portal spaces may cause increase in the size of the liver; later, there is usually contraction.	3. The new tissue is diffused throughout the organ, and causes a great increaso in size.
4. The capsule is much thickened, and the surface is rough and hob-nailed.	4. The capsule is not thickened, and the surface is smooth (like morocco leather).
5. The masses of liver cells vary in size, some consisting of several lobules, others being smaller than a lobule. Each mass forms a *distinct area* with a rounded outline, and is enclosed in a fibrous girdle.	5. The masses of liver cells consist of isolated lobules. The cut surface has a uniform and finely-granulated appearance.
6. On microscopic examination, the process is seen to be going on *chiefly* at the periphery of the lobules. The fibrous tissue is very dense.	6. The fibrous tissue is not confined to the periphery, but invades the substance of the lobules. It is much more open than that of portal cirrhosis.

Symptoms. Atrophic cirrhosis presents gastric catrrh, with anorexia, dyspepsia, nausea, flatulence, diarrhea and sometimes hematemesis. The liver is tender and enlarged at the beginning of the disease. As the disease progresses, and the pressure in the portal system increases, the liver and spleen enlarge, the superficial abdominal veins become prominent, ascites and swelling of the feet are observed, hemorrhoids develop and there may be hemorrhage from the stomach or bowel. Later, the liver gets smaller, the patient loses flesh and strength, slight jaundice may be present, fever, headache, and nervous symptoms (stupor, delirium, convulsions and coma) may appear. In the *hypertrophic cirrhosis* the liver is much enlarged, the spleen enlarged, jaundice is marked, there is pronounced loss of flesh and strength, hemorrhages into the skin and from the mucous membrane may occur, pain in the hepatic region, fever and vomiting are of common occurrence. Ascites and dilated abdominal veins are absent.

Treatment. In *atrophic cirrhosis*, alcohol must be forbidden; for the gastric catarrh, bismuth and alkalies may be adopted; the portal congestion is relieved by salines and diuretics; Epsom salts, compound jalap powder, claterium, squill, digitalis and calomel have been recommended. Paracentesis is indicated for the ascites; epiplopexy has also been suggested. In the *hypertrophic* variety the treatment is symptomatic only, and follows the lines laid down under *atrophic cirrhosis.* The atrophic variety is amenable to treatment in the early stages.

3. Diabetes Mellitus. The *mode of onset* is gradual, and generally it is the frequency of urination or the extreme thirst which attracts the patient's attention. Occasionally the disease sets in somewhat rapidly, following injury or a severe chill or intense and sudden emotion.

The *urinary findings* are: Increased quantity voided, from 3 or 4 quarts to 20 quarts or more in a day; the specific gravity is generally high, 1020 to 1045; the urine is pale in color and has a sweetish odor and taste; the reaction is acid; glucose is present in varying amounts, from 10 to 20 or more ounces being excreted in a day; the urea is increased, and so is the nitrogenous output in general; acetone, diacetic acid, beta-oxybutyric acid are often present; phosphates and sodium chloride are often present in increased quantities; fat and gas in the urine are sometimes met with; albumin may be present.

Treatment. The diet must be carefully regulated, and explicit written directions must be given to the patient. The carbohydrates must be limited, the diet consisting of proteins and fat, the tolerance for carbohydrates must be built up and increased, and a sufficient number of calories must be supplied. With many patients the gradual withdrawal of carbohydrates is tolerated better than their sudden restriction. The percentage of sugar in the urine when the patient is on a general diet is first to be calculated, then the amount on a sugar-free diet, and then the quantity of carbohydrate which can be given without glycosuria appearing. Recently the *starvation diet* of Allen and Joslin has been recommended, but the details of this method are too lengthy for insertion here. Care must be taken lest a diet which is too exclusively nitrogenous should throw an excessive strain upon the liver and kidneys. As a general rule, diabetics *must not take*: Liver, sugars, sweets or starches of any kind, wheaten bread or biscuits, corn bread, oatmeal, barley, rice, rye bread, arrowroot, sago, macaroni, tapioca, vermicelli, potatoes, parsnips, beets, turnips, peas, carrots, melons, fruits, puddings, pastry, pies, ices, honey, jams, sweet or sparkling wines, cordials, cider, porter, lager, chestnuts, peanuts. They may, as a rule, be allowed a diet selected from the following: Soups or broths of beef, chicken, mutton, veal, oysters, clams, terrapin or turtle (not thickened with any farinaceous substances), beef tea, shell fish and all kinds of fish, fresh, salted, dried, pickled or otherwise preserved (no dressing containing flour), eggs, fat beef, mutton, ham or bacon, poultry, sweetbreads, calf's head, sausage, kidneys, pig's feet, tongue, tripe, game (all cooked free of flour, potatoes, bread or crackers), gluten porridge, gluten bread, gluten gems, gluten biscuits, gluten wafers, gluten griddle cakes, almond bread or cakes, bran bread or cakes. String beans, spinach, beet-tops, chicory, kale, lettuce plain or dressed with oil and vinegar, cucumbers, onions, tomatoes, mushrooms, asparagus, oyster plant, celery, dandelions, cresses, radishes, pickles, olives, custards, jellies, creams (without sugar), walnuts, almonds, filberts, Brazil nuts, cocoanuts, pecans, tea or coffee (without sugar), pure water, peptonized milk.

In every case the diet list must be prepared for the individual patient. The general health must also be attended to. The patient should lead a quiet life, free from worry, take gentle exercise, bathe daily in warm water, and only take drugs when indicated. The most commonly used drugs are codeine, morphine, strychnine, arsenic and cod liver oil. For the extreme thirst citrate of potassium or lemon juice with water may be given.

4. Typhoid Fever. *Etiology.* The exciting cause is presence of the *bacillus typhosus.* It may be communicated by contaminated food, milk, water, dust, soiled hands, clothing, instruments or utensils, flies, "carriers," or anything that has become contaminated with the feces, urine or vomitus of one affected with the disease.

The *prodromal symptoms* are vague. There are pain in the head or back or limbs, general depression, anorexia, nausea, chills, headache, epigastric oppression, diarrhea or constipation, disturbed sleep, cough, nosebleed.

Course of the disease. After the prodromal symptoms the patient takes to his bed, and from this the definite onset is generally dated. "During the *first week* there is, in some cases (but by no means in all,

as has long been taught), a steady rise in the fever, the evening record rising a degree or a degree and a half higher each day, reaching 103° or 104°. The pulse is rapid, from 100 to 110, full in volume, but of low tension and often dicrotic; the tongue is coated and white; the abdomen is slightly distended and tender. Unless the fever is high there is no delirium, but the patient complains of headache, and there may be mental confusion and wandering at night. The bowels may be constipated, or there may be two or three loose movements daily. Toward the end of the week the spleen becomes enlarged and the rash appears in the form of rose-colored spots, seen first on the skin of the abdomen. Cough and bronchitic symptoms are not uncommon at the outset. In the *second week*, in cases of moderate severity, the symptoms become aggravated; the fever remains high and the morning remission is slight. The pulse is rapid and loses its dicrotic character. There is no longer headache, but there are mental torpor and dulness. The face looks heavy; the lips are dry; the tongue, in severe cases, becomes dry also. The abdominal symptoms, if present—diarrhea, tympanites, and tenderness—become aggravated. Death may occur during this week, with pronounced nervous symptoms, or, toward the end of it, from hemorrhage or perforation. In mild cases the temperature declines, and by the fourteenth day may be normal. In the *third week*, in cases of moderate severity, the pulse ranges from 110 to 130; the temperature now shows marked morning remissions, and there is a gradual decline in the fever. The loss of flesh is now more noticeable, and the weakness is pronounced. Diarrhea and meteorism may now occur for the first time. Unfavorable symptoms at this stage are the pulmonary complications, increasing feebleness of the heart, and pronounced delirium with muscular tremor. Special dangers are perforation and hemorrhage. With the *fourth week*, in a majority of instances, convalescence begins. The temperature gradually reaches the normal point, the diarrhea stops, the tongue cleans, and the desire for food returns. In severe cases the fourth and even the fifth week may present an aggravated picture of the third; the patient grows weaker, the pulse more rapid and feeble, the tongue dry, and the abdomen distended. He lies in a condition of profound stupor, with low muttering delirium and subsultus tendinum, and passes the feces and urine involuntarily. Heartfailure and secondary complications are the chief dangers of this period. In the *fifth and sixth weeks* protracted cases may still show irregular fever, and convalescence may not set in until after the fortieth day. In this period we meet with relapses in the milder forms or slight recrudescence of the fever. At this time, too, occur many of the complications and sequelæ."—(Osler's *Practice of Medicine.*)

Treatment. "This is largely supportive and prophylactic. On account of the wide distribution of the bacilli in the secretions, it is highly important that the excreta and all substances which come in contact with the patient should be thoroughly disinfected to prevent dissemination of the disease. Corrosive sublimate (1:500), carbolic acid (1:10), and chlorinated lime are used to disinfect the stools. Weaker solutions may be employed for sponging the perineum and anal region of the patient and for washing the hands of the attendants. The general treatment consists in absolute rest in bed with the enforced use of the bed-pan. The diet should be liquid, largely milk, and should be administered every three hours. The modern tendency is toward a more liberal diet, and the high calory diet (as advocated by Coleman) adds to the comfort of the patient, shortens the convalescence and lowers the death-rate. Fever should be controlled by sponging, by the wet pack, and by the full bath. The Brand method consists in immersion of the body in a tub of water (70° F.) for 15 or 20 minutes every third hour when the temperature rises above 102.5° F. The medicinal treatment includes the use of antipyretics, intestinal antiseptics, and antityphoid serum. Abdominal pain, tympanites, and tenderness are best treated with fomentations and turpentine stupes, while meteorism may be relieved by the internal administration of turpentine and by the use of the rectal tube or injections of the milk of asafetida (ʒ 5-6). Diarrhea, when it exceeds 4 or 5 stools daily, will require the withholding of all food except milk and the administration of opium, bismuth, codeine, etc. Constipation should be relieved every 2 days by enemas containing soapsuds. When hemorrhage occurs, the foot of the bed should be elevated, an ice-bag or iced cloth should be applied to the abdomen, morphine should be given hypodermically, and opium (gr. 1) should be administered by the mouth every three hours. Peritonitis usually terminates fatally, and requires the same treatment as hemorrhage. Abdominal section should be performed as soon as the diagnosis is positive. Alcohol, ammonia, strychnine, digitalis, etc., should be used if heart-failure supervenes. Nervous symptoms are greatly lessened by hydrotherapy, but nerve-sedatives may be necessary. Sore mouth may be prevented by cleanliness and the use of carbolized glycerin solution (0.5 per cent.) upon the gums and teeth."—(*Pocket Cyclopedia.*)

5. *Impetigo contagiosa* is an acute, contagious, inflammatory disease of the skin, characterized by discrete, flat, superficial vesicles or blebs, which rapidly become pustular and dry upon the skin as thin crusts. The eruption is most common upon the face and hands. The lesions begin as flat vesicles or blebs, which, in the course of twenty-four hours, become vesiculopustular or pustular. Rupture soon occurs, the exudate drying upon the skin as thin, wafer-like crusts, which appear to be "stuck on." The edges of the crusts become detached, curl up, and the crusts drop off, exposing to view reddish spots which soon fade. The lesions at times show a tendency to umbilication. A coalescence of neighboring pustules may occur, leading to the formation of patches of considerable size. In severe cases there may be slight febrile disturbance. Itching is slight or absent. Occasionally the eruption takes on a circinate form. The affection is chiefly seen in poor children. It is likely to accompany pediculosis capitis, as the result of scratching. Epidemics of contagious impetigo are not uncommon in institutions for children. The affection is caused by inoculation with the ordinary pus microorganisms, particularly the staphylococcus pyogenes aureus. The chief characteristics are the discreteness, superficiality, and autoinoculability of the lesions. The affection may be cured in a week or ten days, or, indeed, may get well spontaneously. The crusts may be removed with soap and warm water, after which an ointment of ammoniated mercury (gr. xxx to 1 ounce of petrolatum) should be applied; mild antiseptics may be employed, care being taken to avoid irritation.—(*Cyclopedia of Medicine and Surgery.*)

Herpes zoster is probably an acute specific disease of the nervous system, characterized by the formation of grouped vesicles along the line of a cutaneous nerve, and accompanied by neuralgic pains. Cold, anemia, excessive use of arsenic, malaria have been mentioned as causative factors. There is an irritative or inflammatory condition of the central, spinal, or peripheral nerve apparatus. The process is usually an interstitial descending neuritis of one of the spinal ganglia. The parts affected should be protected from injury by a dusting powder or collodion; the pain may demand morphine. Internally, zinc phosphide, and tonics have been recommended.

Alopecia areata is a disease of the hairy system characterized by the more or less sudden occurrence of round or oval, circumscribed, bald patches, in rare cases coalescing and producing total baldness. The cause is usually neurotic in character, although at times the disease seems to be caused by a parasite. The characteristics of the disease are the circumscribed areas of baldness, the pale, smooth skin, the contracted follicles, and the rapid onset. Internally, arsenic, in addition to other tonics and stimulants, is of great service. Locally, stimulation of the scalp is indicated, for which purpose the essential oils, cantharides, capsicum, turpentine, and sulphur are recommended. The faradic current applied with a wire-brush electrode is often useful. In obstinate cases blistering may be resorted to.—(*Pocket Cyclopedia.*)

SURGERY.

1. (*a*) *Benign tumors* of the breast are generally found in young women, between the ages of 15 and 30. They grow very slowly and gradually. As a rule they are freely movable, are firm, round and oval, and the nearer they are to the skin the softer they are. They are not encapsulated, and don't cause retraction of the nipple or enlargement of the axillary glands. As a rule they are not painful. *Malignant tumors* are generally found in women between 30 and 60 years of age. Cachexia accompanies them. They grow rapidly. They are movable in the early stages, later they become adherent to the skin or pectoralis major muscle, and are hard and immovable. The nipple is retracted. The axillary glands are enlarged. Pain is a symptom. There may be metastatic growths.

(*b*) In *doubtful cases* it is well to imagine the growth to be malignant until it is proved otherwise. If the breast is removed, and the tumor is proved benign, the woman has lost a breast; whereas, if it is not removed, and should prove to be malignant, she will lose her life. The best plan is (with the consent of the patient) to prepare for a radical operation, excise a piece of the tumor, have it examined microscopically, and if it proves to be benign, remove the tumor; if it is malignant, remove the whole breast and neighboring lymphatic glands.

(*c*) *"Halsted's operation* aims to remove in one piece the entire breast and overlying skin, the costal portion of the pectoralis major, the pectoralis minor, and all the fat and glands of the axilla. The supraclavicular glands are removed in a second piece. An incision is carried through the skin and fat, and a triangular flap turned back. The costal portion of the pectoralis major is divided close to the ribs and separated from the clavicular portion, which with the overlying skin is divided up to the clavicle, exposing the apex of the axilla; these flaps are drawn upward with a retractor and separated from the underlying tissues, and the muscle further split as far as the humerus, where it is severed close to the bone. The breast, pectoralis major, and all fat are stripped from the chest wall, including the pectoralis minor, which is divided at each end, thus exposing the entire axilla, which is cleansed of fat and lymphatic glands from above and within, downward and outward, all small vessels being ligated close to the axillary vessels, which, with the nerves, should alone remain. The triangular flap of skin is drawn outward and the lateral and posterior walls of the axilla likewise cleared, the subscapular vessels being ligated, and the subscapular nerves preserved if possible. The mass is then turned inward and removed from the chest. A vertical incision is now made along the posterior margin of the sternomastoid, and the supra- and infraclavicular fat and glands removed by dissecting from the junction of the internal jugular and subclavian veins downward and outward. The cervical wound is sutured, and the edges of the chest wound approximated by a buried purse-string suture of silk, which includes the base of the triangular flap, the apex being spread over the axilla. The rest of the wound is covered with Thiersch's skin grafts. The axilla is not drained. The disability resulting after such an extensive operation is surprisingly slight. The entire wound may be closed in most cases by fashioning two flaps from the lower lip of the wound. A small gauze drain should always be placed in the axilla, preferably through a small incision at its posterior margin, in order to drain the large quantity of fluid which escapes from the severed lymph vessels."—(Stewart's *Surgery.*)

2. *Intussusception* is the telescoping of one part of the intestine into the part immediately below. It is said to be due to irregular peristalsis; trauma, diarrhea, intestinal worms, polypi and new growths in the intestinal wall have all been credited with causing the condition.

(*b*) *Acute intussusception* is most common in children. It begins suddenly with severe abdominal pain and vomiting. Blood-stained mucus is passed, perhaps with tenesmus. Collapse soon comes on, and may be fatal in twenty-four hours; otherwise death occurs in a few days from peritonitis. In most cases a "sausage-shaped" tumor can be felt, usually along the course of the colon, but lower down, or just above the pubis The right iliac fossa feels empty. A natural cure may follow, but rarely, from sloughing of the intussusceptum, whilst the peritoneal cavity is protected by adhesions uniting the entering and ensheathing layers.

(*c*) *Treatment.* "The reduction of the intussusception at the earliest possible moment is the only treatment admissible, and this can only be done with certainty by operation. The abdomen should be opened over the tumor if it can be felt; if not, in the mid-line below the umbilicus. The intussusception is then reduced by squeezing out the entering portion, beginning at the lowest part. The intestine should never be pulled out, for fear of tearing it. If there is any difficulty, the wound must be enlarged and the lump brought out. If, owing to adhesions, reduction cannot be done, the intussuscepted portion must be excised through an incision in the ensheathing layer, but the outlook is bad in these cases. If the bowel is gangrenous, the condition is so bad that nothing more can be done than to bring out the coil and establish an artificial anus. If, owing to any reason, an operation is not possible, nonoperative procedures must be tried. These consist of attempting to reduce the invagination by inflation with air or, better still, by fluid. A catheter is passed into the rectum and fluid poured in from a funnel raised not more than 2 feet. A hand is placed over the tumor to feel when the lump disappears. The objections to this are that after twelve hours reduction cannot be obtained by this method; that valuable time is wasted if it fails; that you cannot tell if the last inch has been reduced (and if it has not, recurrence is certain); that it is no use in the enteric or ileocolic forms, and that the bowel may be ruptured."—(*Aids to Surgery.*)

5. (*a*) *Amputation in the middle of the forearm.* "An anterior and a posterior U-shaped flap are incised on the respective aspects of the forearm, the base of each flap at the saw-line being equal to a half-circumference of the limb at that line and the length of each equal to three-fourths of the diameter—the hand being supinated in making the anterior flap and the forearm vertical in making the posterior flap. Having cut through skin and fascia in outlining the flaps, these incisions are now deepened upon the line of the retracted skin, beginning at the ulnar side of the anterior flap, in case of the right arm (and on the radial side upon the opposite arm). The vertical ulnar incision will involve the flexor carpi ulnaris and flexor profundus—the vertical radial incision will involve the two radial carpal extensors—both vertical incisions passing directly to the bones. The muscles on the anterior and posterior aspects of the forearm, at the lower rounded extremities of the flaps, are cut from without inward in such a manner as to bevel them slightly. The entire flaps are now raised from the bones up to a point sufficiently below the saw-line to furnish a musculoperiosteal covering—at which level the periosteum is circularly divided around the bones, the interosseous membrane cut transversely, and the musculoperiosteal covering freed to the saw-line. The soft parts are then retracted and the bones sawed. The radial, ulnar, anterior and posterior interosseous arteries are tied. The median, radial, and ulnar nerves should be cut short, or even dissected from the flap. The musculoperiosteal covering is sutured and the muscles quilted—and the integuments sutured in a lateral line."—(Bickham's *Operative Surgery.*)

(*b*) In amputation of forearm at middle third there will be severed: Skin; fascia; muscles:—supinator longus, extensor carpi radialis longior and brevior, extensor communis digitorum, extensor carpi ulnaris, supinator brevis, anconeus, pronator radii teres, flexor carpi radialis, palmaris longus, flexor sublimis digitorum, flexor carpi ulnaris, flexor profundus digitorum; arteries:—anterior interosseous, posterior interosseous, radial, ulnar; veins:—radial, interosseous, ulnar, median; nerves:—posterior interosseous, radial, median, ulnar; bones:—radius, ulna.

4. *Anal fissure* is characterized by the very severe pain on defecation, and for some time afterward; constipation and pruritus are commonly present; local examination shows a "sentinal pile," on the inner side of which is a very painful ulcer or fissure.

Hemorrhoids. The patient complains of a feeling of weight, itching, tenesmus. There is but little pain unless a fissure or ulcer is also present. Internal hemorrhoids, if protruding, are painful; bleeding may be severe. The hemorrhoids are readily seen if external; internal hemorrhoids may be seen if the patient strains, or they protrude during defecation.

Carcinoma of the rectum generally attacks persons past middle age. At first there may be no symptoms beyond itching and occasional bleeding; then diarrhea, straining at stool, the discharge of pus or mucus may be observed; pain may be present, which radiates to the back and thighs. Under anesthesia the carcinoma may be seen by the proctoscope or felt by the examiner's finger. In the later stages cachexia develops and the symptoms of stricture are present.

Treatment of anal fissure. The base of the fissure (including the external sphincter) must be divided: all piles (including the "sentinal pile") must be removed; the ulcer must be excised. The wound then heals by granulation. The bowels must be kept relaxed.

The *treatment* of *external piles* when uninflamed consists in preventing constipation, keeping the parts clean, and applying hamamelis ointment. They seldom need removal except when associated with internal piles. Inflamed piles should be treated by rest, a large warm enema, and fomentations. If there is much pain the pile should be incised and the blood-clot turned out.

The *treatment* of *internal piles.* Constipation must be avoided, also excesses in eating and drinking. The

parts must be carefully cleansed and hamamelis ointment applied. Operations include clamp and cautery, ligature, and Whitehead's operation.

Operation for hemorrhoids. Clamp and cautery. *Radical treatment* is advisable when there is much pain and bleeding. It must be ascertained first that the piles are not due to disease elsewhere, as cirrhosis or stricture, or to pregnancy. The bowels are emptied and the patient is placed in the lithotomy position. The sphincter is then dilated with two thumbs to expose the piles, which are caught up with ring forceps. A clamp is applied to the piles in turn, and they are removed by the cautery. The bowels are kept confined for five or six days, when castor oil is given. Very little pain and no bleeding follow this operation. Removal can be done by snipping the mucous membrane around the pile and ligaturing its base. Crushing is also done.—(*Aids to Surgery.*)

The *treatment of cancer of the rectum* is excision of the rectum or colostomy. *Kraske's operation* (excision of the rectum by the sacral route): "With the patient lying on the right side, a median incision is made from the anus to the middle of the sacrum. The coccyx is excised. The ligaments and muscles are detached from the sides of the sacrum as high as a point just below the third sacral foramina, at which point the sacrum is sawn across and the lower piece removed. The rectum is exposed and cut through above and below the growth. The peritoneum may have to be opened to get above the tumor. If the sphincter and anus are unaffected they are left and the bowel is brought down and an end-to-end anastomosis is made. If the whole rectum has to be removed the upper end is either brought down and stitched to the skin around the original anus, or, if this is not possible, an anus is made just below the divided sacrum. During the operation the sacral glands must be searched for and removed if enlarged. Incontinence usually remains, and is less easy to manage with a truss than a colotomy."—(*Aids to Surgery.*)

5. "If the disease is at the *cardiac end* of the stomach, involving the cardiac orifice, the symptoms may resemble those of stricture of the esophagus and be associated with dysphagia, ending in an inability to swallow at first solid and later even fluid nourishment; in such cases the tumor, being well under cover of the ribs, is difficult or impossible to palpate, but enlargement of the supraclavicular glands on the left side is usually present.

"If the *pylorus* be the part involved, dilatation of the stomach with retention and decomposition of food and vomiting are pronounced symptoms, the vomiting being at first irregular, perhaps every second or third day, soon becoming daily and later occurring after every meal. Peristalsis may be accompanied by severe pain of a crampy character which is relieved by vomiting."—(Keen's *Surgery.*) There may be felt a tumor a little above and to the right of the umbilicus, at first movable but later fixed by adhesions. The pylorus becomes stenosed. In the later stages there are pressure symptoms, such as ascites, jaundice, edema of the legs, and varicose veins in the abdominal walls.

Treatment. When the *cardiac* end is involved only palliative operations are recommended; gastrostomy may be tried. When the disease is at the *pyloric* end, "complete removal of the affected segment of stomach and of the associated lymphatics is the only means of curing the disease. In many cases it is only after the parts have been exposed by laparotomy that it is possible to say whether or not the radical operation should be undertaken. If the associated glands are capable of being removed, and if there is no evidence of metastasis having occurred, the radical operation should be carried out. The term *pylorectomy* is applied when the operation is performed for malignant disease of the pylorus, although a considerable portion of the stomach must also be removed. Adhesion to and infiltration of the transverse colon is not usually a contraindication to the radical operation, as it is quite feasible to resect the portion of colon involved. The technique of the operation has been simplified by the preliminary ligation of the arteries distributed to the stomach and by the use of clamps. In the majorty of cases it is best to perform gastroenterostomy in the first place, choosing a healthy portion of the stomach; the resection is then carried out and the cut ends of the stomach and duodenum closed and invaginated. In weakly patients an interval may be allowed to elapse between the gastroenterostomy and the resection. The radical operation is contraindicated when the disease is associated with ascites, when the tumor has infiltrated the omentum, liver, pancreas, or abdominal wall, or when metastasis has occurred."—(Thomson and Miles' *Manual of Surgery.*)

OBSTETRICS AND GYNECOLOGY.

1. The patient should be instructed fully in the hygiene of pregnancy, by which is meant the care which should be observed by the pregnant woman for the preservation of health and strength both of herself and of the fetus. The pregnant woman should take moderate exercise in the open air; in the last month massage may take the place of exercise. Daily bathing in tepid water, care of the teeth, regularity of the bowels, ample sleep in a well-ventilated room, plenty (but not too much) of simple, nourishing and easily digested food at regular hours, clothing not too tight, especially about the abdomen and breast; attention to the nipples, regular examination of the urine, and the restriction of marital relations are the main points to which advice should be directed. In addition certain measurements are necessary; a pelvimeter will be required to make these measurements. The interspinal and intercristal diameters are measured, also the distance between the ischial tuberosities and the anteroposterior diameter, as well as the external conjugate. It is well to notice if the subpubic arch is narrowed; the diagonal conjugate is also estimated; from the latter the true conjugate can be obtained.

Care of mother during puerperium. "*During the first week* the patient keeps the bed, but after the first few hours she has considerable license. She may assume the sitting or halfsitting posture to take her meals and to nurse the baby, and, if necessary, for evacuation of the bladder and rectum. She should assume the lateroprone posture both right and left several times a day, and lie upon her abdomen for at least an hour daily. Frequent change of position favors uterine drainage and massages the uterine supports. *During the second week* she has greater liberty, while the greater part of her time is spent on the bed or lounge. She may sit up for her meals, to urinate, and for bowel movements, and she should spend at least half an hour, twice daily, in abdominal and leg exercises to keep up her muscular tone. *The third week* she may be moved to a chair for a part of the day, having the liberty of the room. After sitting up for any length of time she should be instructed to take the genupectoral position before lying down. Prescribed exercises for the legs and abdominal muscles are to be taken daily. *The fourth week*, if all goes well, she may leave the room and have the benefits of air and sun. Physical exercises should be continued. The duration of the lying-in period and the degree of freedom to be given the patient after the second week must, however, depend on the character and amount of the lochia, the general progress of her convalescence, and the rate of the uterine involution."—(Polak's *Obstetrics.*)

2. *True labor pains* are the pains occurring at the commencement of labor, and which are coincident with expulsive efforts of the uterus. They begin at the back, pass to the front, occur at gradually shortening intervals, are accompanied by uterine contraction and increased opening of the os externum.

False labor pains occur before labor. They are feeble, do not last long, occur at long intervals, are not accompanied by contraction of the abdominal muscles, are generally felt in front, and do not cause opening of the os.

Weak pains are such as do not aid much in the expulsion of the fetus.

Cutting pains are the early pains experienced by the woman, and are so called from the "cutting" sensations experienced by the woman.

Atonic pains are the ineffective pains accompanying a condition of uterine inertia; the uterus does not harden to any extent, and contracts feebly and irregularly.

Expulsive pains are such as produce or accompany the expulsion of the fetus.

After pains are painful contractions of the uterus which occur after delivery (generally for two or three days).

3. *Indications for the use of forceps are:* "1. *Forces at fault:* Inertia uteri in the presence of conditions likely to jeopardize the interests of mother or child. (*a*) Impending exhaustion; (*b*) arrest of head, from feeble pains. 2. *Passages at fault:* Moderate narrowing 3¼ to 3¾ inches, true conjugate; moderate obstruction in the soft parts. 3. *Passenger at fault:* A

Dystocia due to (*a*) occipitoposterior, (*b*) mentoanterior face, (*c*) breech arrested in cavity. B. Evidence of fetal exhaustion (pulse above 160 or below 100 perminute). 3. *Accidental complications:* Hemorrhage; prolapsus funis; eclampsia. All acute or chronic diseases of complications in which immediate delivery is required in the interest of mother or child or both."—(From Jewett's *Practice of Obstetrics.*) *Contraindications:* Mechanical obstruction in the parturient canal; incomplete dilatation of the os; non-rupture of membranes; non-engagement of the presenting part; the fetal head being too large or too small; distended bladder or rectum.

Pituitrin may be used in cases of uterine inertia, provided the os is dilated and there is no obstruction to delivery.

4. The condition may be anyone of the following: Pregnancy, uterine fibroid, ascites, ovarian cyst, fat, pseudocyesis, and subinvolution of the uterus.

Pregnancy: The tumor is hard and does not fluctuate, is situated in the median line, and may give fetal heart sounds and movements; the cervix is soft, and the other signs of pregnancy are present. The rate of growth of the tumor and the general condition of the patient's health may also help in arriving at a diagnosis.

Uterine fibroid: Menstruation is irregular and sometimes very profuse; absence of the signs of pregnancy; the tumor is nodular, firm, irregular in outline, and while generally placed somewhat centrally is not in the median line, and is not symmetrical; the rate of growth is irregular, being, as a rule, slow, and sometimes extending over years.

Ascites: Absence of the signs of pregnancy; the abdomen is distended, but the shape varies with the position of the patient; on lying down there is bulging at the sides, the tumor fluctuates, and percussion shows dullness in the flanks, with resonance in the median line, but the dullness varies with the position of the patient.

Ovarian cyst: Absence of the chief signs of pregnancy; there may be the characteristic facies, the tumor is soft, fluctuating, is more to one side, and does not show fetal signs.

Fat: Absence of signs of pregnancy, also of fibroid, or ascites.

Pseudocyesis: The uterus is not enlarged, and the administration of a general anesthetic causes the collapse of the "tumor."

Subinvolution of uterus: The uterus does not increase in size, there is a leucorrhea, there is generally pain in the back or ovarian region, there is a history of irregular (and profuse) menstruation, and the signs of pregnancy are absent.

5. PROLAPSUS UTERI. *Etiology:* Injury at childbirth, lacerated perineum, relaxation and elongation of the ligaments of the uterus, loss of rigidity of the abdominal walls, increase in the weight of the uterus, subinvolution, increased intraabdominal pressure. *Symptoms:* The patient complains of a feeling of "bearing down"; of trouble with micturition and defecation; of pain and fatigue on walking, and of "falling of the womb." The cervix is low down in the vagina; the sound shows that the uterine cavity is lengthened. Procidentia is evident on inspection. *Treatment:* "A prolapsed uterus must first be placed in proper position, or a procidentia reduced. In many cases the introduction of a rubber ring pessary will then suffice to prevent recurrence. But it will often be found necessary to repair a torn perineum, removing at the same time redundant portions of the vaginal walls, before the ring will remain in the vagina. When such an operation is contraindicated, and the vaginal orifice is so wide that a ring cannot be kept in, some form of pessary with a vaginal stem and perineal bands will be required. In cases of procidentia, where the exposed surface is much ulcerated, the patient should be kept in bed, emollient applications made to the ulcers, and vaginal douches given. When the ulcers have healed, a pessary may be introduced. Procidentia due to supravaginal elongation of the cervix must be differently dealt with. Amputation of a portion of the cervix must therefore form the first step in the treatment, and it may be required also when the hyperplasia is secondary to descent. Cases of prolapse and procidentia which resist milder measures require further operative procedures, such as ventrofixation of the uterus or the shortening of the round ligaments. It is in cases of this kind that hysteropexy has often given satisfactory results. Total extirpation of the uterus has been practised for the treatment of procidentia."—(Sutton and Giles' *Diseases of Women.*)

THE SCOPE AND TECHNIQUE OF *X*-RAY THERAPY.*

BY ISAAC LEVIN, M.D.,

NEW YORK.

CLINICAL PROFESSOR OF CANCER RESEARCH, NEW YORK UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE; CHIEF OF THE DEPARTMENT OF CANCER RESEARCH OF THE MONTEFIORE HOSPITAL AND HOME.

X-RAYS as will be shown later are in many respects quite analogous to the rays of light. The spectrum of the so-called white light may be divided into four parts. One part situated at about the middle of the spectrum, consists of the so-called visible rays of light, *i. e.* those rays which are so constructed that they produce a certain impression upon the retina of the eye, and as a consequence, appear to our consciousness as rays of light of different color, varying from red to violet. Below the red rays there are a number of rays which are invisible, and when analyzed appear to be the source of heat. At the other extreme end of the visible rays, *i. e.* beyond the violet, there are a set of rays which are also invisible, and exert various chemical influences on the substances which they strike. Still further along the spectrum, beyond chemical or actinic rays, are rays which are known as the *x*-rays, and beyond these the gamma rays of the radioactive substances.

The significance of radiant energy in the maintenance of all plant and animal life is very evident. Let us stop to think for a moment of the following very simple experiment. If two hen's eggs are placed in separate small wooden boxes, the only difference being that one box contains a small electric light bulb which warms the box to a certain degree, the other box being cold, it will be found after the lapse of three weeks that the egg in the cold box has remained unchanged, while the egg in the warm box has hatched. Both eggs contained a fertile germ, and consequently the rays of heat were indispensable for the development of the living organism.

The ability of a plant to assimilate the inorganic substances of the air and soil and change them into its own organized constituent parts is due to the chlorophyll, which performs its functions only in the presence of light. In complete darkness the plant loses its green color, *i. e.* the chlorophyll is unable to assimilate inorganic food, and dies. Where there is no plant life in existence, animal life which can feed only on organic substances is inconceivable; consequently neither plant nor animal life can exist in the absence of light.

Every therapeutic measure, in its ultimate analysis, influences the life and metabolism of the cell; and it is evident, therefore, that light, which is capable of affecting to so great a degree the life of the cell, plant or animal, must be of great therapeutic value. This was appreciated at the very beginning of known civilization, even the old Egyptians, according to the statements of Herodotus, placing their sick in the hot sand under the direct rays of the sun.

The discovery of the *x*-rays by Roentgen and of the rays of the radioactive substances by Becquerel was immediately followed by attempts to utilize these rays for therapeutic purposes. The opinion still prevails today, however, as it did during the second half of the Nineteenth Century, that only organic and inorganic substances which are chemically or rather pharmacologically active when introduced into the organism have any therapeutic value. Physical methods of treatment are regarded with distrust and hardly find a place in the curriculum of any medical school or in the text-books of pharmacology and therapeutics. Until recently this opinion was in a way natural and in accord with the conceptions of the relative positions of physics and chemistry. It has been considered a scientific axiom that physics dealt only with laws of energy and with such changes in the constitution of matter as left each molecule undisturbed, while chemistry on the other hand, studied the conditions within each molecule of matter, and chemical forces were capable of splitting the molecule into its component parts—atoms. It was further accepted as an axiom that an atom cannot be divided any further. Chemistry, then was thought to be capable of producing the deeper changes within matter, and consequently within the organism than physics.

It will be shown later that the hypotheses of the structure of matter, the nature of energy, and the interrelation of the two have radically changed in the course of the last two decades. If the functions of the science of physics as known during the last century may be called intermolecular and the functions of chemistry, interatomic; then the activities of physics, as they are understood today, are even more than interatomic; they are intraatomic since purely physical agents are capable of breaking up the presumably indivisible atom into its component parts.

In view of all this, we must learn to readjust our therapeutic conceptions as well. The therapeutic action of radiant energy must not be confused with the purely mechanical methods of physiotherapy. Indeed, if the modern conceptions of the structure of matter be taken into account, then the method of radiotherapy is very similar to, if not identical with the method of chemotherapy. In both instances, the ultimate effect consists in a disturbance and rearrangement within the atom of matter. The difference between the two methods consists in the fact that in chemotherapy a foreign

*Read by invitation at the meeting of the New York Roentgen Ray Association, March 31, 1916.

chemical substance is introduced into the organism, and influences the electrons within the atoms of the tissues, while in radiotherapy no foreign substance is introduced, but the waves of ether constituting the various rays disturb the composition of the atom.

It is interesting to draw a comparison between the therapeutic and physiological action of radiant energy and of the arsenicals, the most potent of the known chemotherapeutic agents. Both act in a similar manner, in small quantities they stimulate cell metabolism, cell growth, and all other cell functions. The following excerpt from the most recent edition of "Die experimentelle Pharmakologie" by Meyer & Gottlieb, describing the pharmacological action of arsenic illustrates the point: "In a normal organism there are injured the cells of the most complex organs, as the liver, kidney, capillaries, and the blood, but certain new formations, as the malignant lymphomata, syphilitic gummata, etc., seem most easily to undergo destruction under the influence of arsenic; this phenomenon makes it possible for the arsenic to influence abnormal growth without producing any apparent or permanent change in the normal tissues." The action described here is quite analogous to the action of the radiations.

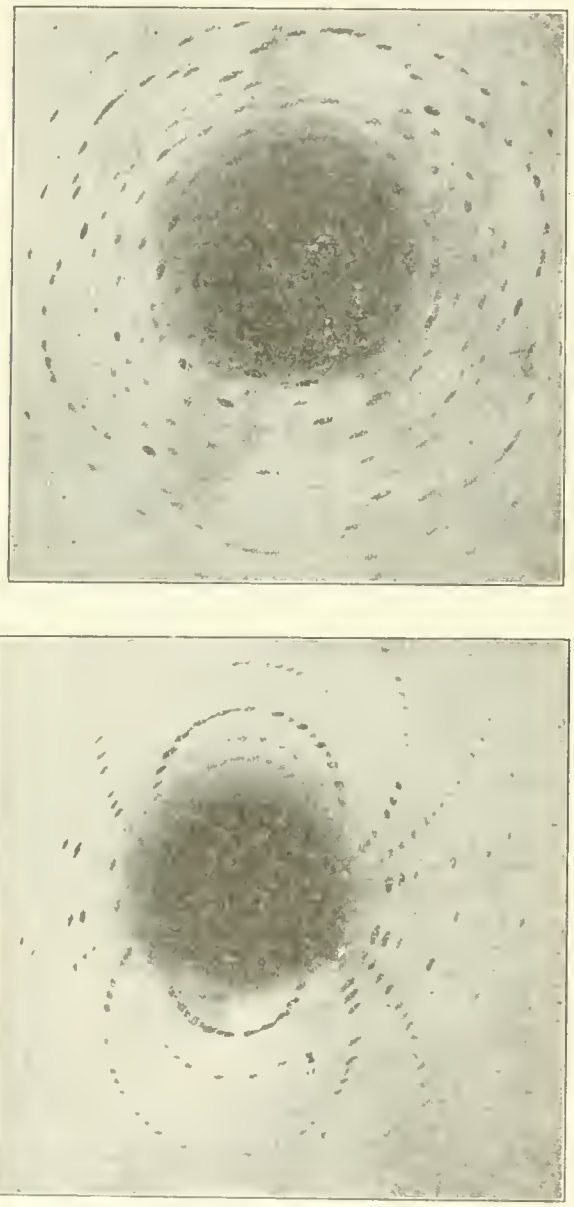

FIG. 1.—*X*-ray photograph of two crystals—nickel sulphate (below) and beryl (above).

Radiant energy, then, is capable of inducing changes in the atomic structure of the constituent parts of the tissues, without the introduction into the organism of any foreign substance. It is self-evident that whenever either a chemical substance or radiant energy may be used with equal effect in the treatment of a certain disease radiotherapy should be the method of choice.

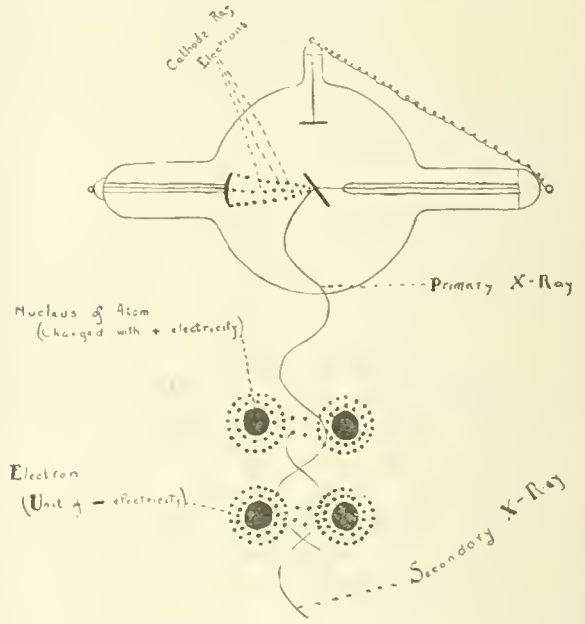

FIG. 2.—A symbolical drawing of the structure of matter and the action of *x*-rays upon it.

Like any chemotherapeutic agent, radiant energy is not a true specific, such as diphtheria antitoxin, but none the less, as will be shown later, its action may be quantitatively selective; *i. e.* a certain quantity of radiation which is not sufficiently strong to have a deleterious effect on the normal tissues of the organism, may influence the

FIG. 3.—Radiated and control plants (in text). The dotted lines show the comparative length of the whole plant and the intranodular spaces.

pathological tissues and consequently have a selective curative effect.

Physics of X-rays.—*X*-rays are in many respects analogous to the rays of light. They move in straight lines, they traverse space without any

Fig. 4.—*a*, Radiated tadpole; *b*, normal control tadpole

obvious transference or intervention of matter, they act on a photographic plate, excite certain materials to phosphorescence, and bring about the ionization of gas. The only characteristic of light which *x*-rays do not possess is the deflection by prisms or lenses. But very recent investigations have shown that such a deflection may be obtained when crystals are used instead of mirrors or prisms. If a pencil of *x*-rays is made to traverse a crystal, diffracted pencils are formed, arranged about the primary beam in a regular pattern, according to the structure of the crystal. A photographic plate placed perpendicular to the primary rays and behind the crystal would show a strong central spot where the primary rays struck it, and other spots arranged in regular fashion around the central spot in the places struck by the diffracted pencils. Fig. 1 from W. H. Bragg & W. L. Bragg, "*X*-ray and Crystal Structure" shows this.

Thus it seems quite reasonable to suppose that the rays of light and the *x*-rays are qualitatively identical. The difference between the two kinds of rays consists in the fact that the waves of ether forming the *x*-rays are considerably shorter than the shortest ultraviolet waves of light. The waves of the so-called soft *x*-rays are about one thousand times shorter than those of ultraviolet light, and the waves of the hard *x*-rays are still shorter. The truth of this assumption is further enhanced by the fact that the photographs shown in Fig. 1 were calculated mathematically before they were proven by experiment.

All substances, when exposed to a beam of *x*-rays, absorb a part of the rays. The fraction of the rays thus absorbed depends upon the density, thickness and the atomic weight of the substance. The remaining rays penetrate beyond the interposed substance. Besides this, the primary *x*-rays produce within the substance the formation of secondary cathode rays: *i. e.* swiftly moving electrons; and also secondary *x*-rays. Fig. 2 gives a rough symbolic sketch of the production of secondary cathode and *x*-rays in matter exposes to primary *x*-rays. In accordance with Rutherford's conception of the structure of matter an atom consists of a large nucleus charged with positive electricity, surrounded like a planet by satellites, by two circles of negatively charged electrons. One of the circles of electrons, the so-called "valency" electrons, takes part in the chemical reactions of the atoms. The other circle of "emission" electrons gives rise to the absorption of radiations by the substance. In metals there are also present "free" electrons between the atoms, to which the electrical conductivity of a metal is due. An electron is the smallest unit of matter known today and is at the same time presumably an independent unit of electricity; in other words, it is something which links together as it were matter and energy. The minute spaces between the atoms contain the hypothetical ether which is supposed to penetrate all space in nature. When a pulse in the ether is short enough to penetrate between the atoms (*i. e.* hard *x*-rays), it sets in rapid motion a certain number of the electrons and thus creates secondary cathode rays. The rapidly moving electrons, on the other hand, create new pulses in the ether situated between the atoms; *i. e.* create secondary *x*-rays. Very recently Rutherford showed that the G-rays emitted by radium may be regarded as secondary *x*-rays produced in the radium by the action of B-particles; *i. e.* electrons, which latter are consequently analogous to secondary cathode rays. Fig. 2 shows graphically the relationship in space between the cathode rays or electrons of the cathode of an *x*-ray tube, the primary *x*-rays, the positively charged nuclei of an atom, the circles of electrons surrounding the atom of matter, the free electrons between the atoms which act as the secondary cathode rays, and the secondary *x*-rays. The character of the secondary *x*-rays will be the same, for instance whether the primary *x*-rays penetrate a certain metal or solution of a salt of the same metal. This conception of the structure of matter and the nature of the *x*-rays makes clear the importance of the three main characteristics of the rays; namely, the *penetration*, the *absorption*, and the *selective action*. Hardest *x*-rays, *i. e.* shortest waves of ether, *penetrate* between the atoms of matter without affecting the substance in any manner. Soft rays, *i. e.* longer waves of ether, are unable to penetrate between the atoms of the substance and are *dispersed* over the surface of the substance and again produce no effect on the latter. Only when the relationship between the atomic structure of the substance and the wave length of the *x*-rays is correct does there take place a *selective absorption* of the rays by the substance, and the latter is then influenced by the rays.

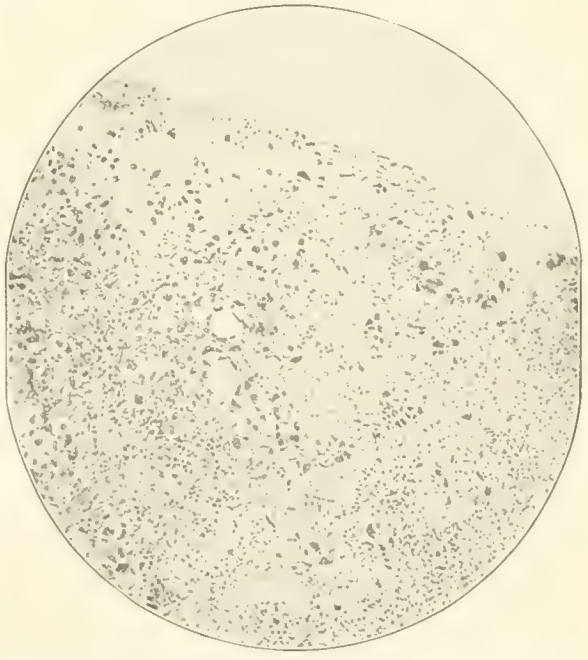

Fig. 5.—Microphotograph of a piece of carcinomatous tissue removed from the cervix uteri soon after the beginning of radium and *x*-ray treatment. It shows degenerated cancer cells surrounded by a round-cell infiltration.

Biological Action of X-rays.—The biological action of the *x*-rays is also analogous to the action of light. This analogy is very evident in the so-called *x*-ray burn of the skin. When a large dose of soft

x-rays is applied to the unprotected skin there takes place an erythema, blistering, and ultimately the condition is qualitatively identical with a sunburn and only differs from it in degree. The browning of the skin which takes place as a result of an x-

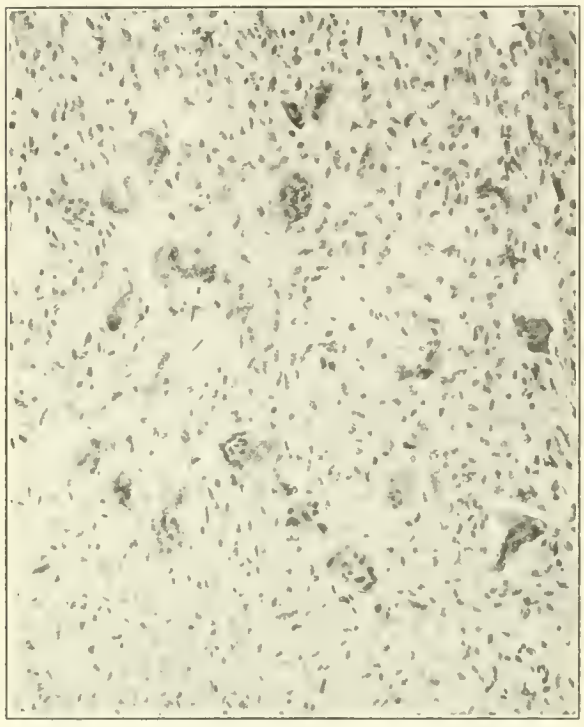

Fig. 6.—Microscopical section of a sarcoma before treatment, showing numerous giant and spindle cells.

ray burn, or occasionally after x-raying of the skin even without the formation of a burn is identical with the pigmentation of the skin after a sunburn. Here again the difference is only in degree.

Fr. Bernig in a recent review states that the rays of light, or rather of ultraviolet light, which is biologically the most active part of the spectrum, produce the following effects on the skin: Direct destruction of the cells; thrombosis of the blood vessels (through the direct influence of the rays on the endothelium and musculature of the vessels) and serohemorrhagic inflammation. The latter ends with the formation of hyperthrophic connective tissue. These morphological changes are very similar to the changes induced in tissues by x-rays.

The analysis of a biological action of any agent is much simpler in the uncomplicated cellular structure of a plant or lower animal than in a vertebrate. A. Richards came to the following conclusion from his studies on the effect of x-rays on the rate of cell division in the early cleavage of the eggs of Planorbis. The first effect of exposure to x-rays upon the rate of cleavage of the eggs of Planorbis is to stimulate mitotic activity. Following the phase of acceleration a phase of depression sets in; the end result is a marked retardation in the development of the egg.

It is quite possible that the action of x-rays on plant and animal tissue is identical with the action of the rays on metal. To cite an instance: x-rays produce a marked biological effect on erythrocytes, and the hemoglobin of the latter contain a solution of iron. It is known that active secondary rays are produced in iron by the x-rays penetrating it.

The most marked biological effect of x-rays on plants and vertebrate animal organism also consists in inhibition of life functions. Fig. 3. is taken from Gaus & Lembcke "Roentgentieftherapie" and represents three plants (edible peas). The largest one is a control, the upper left plant was radiated with soft x-rays and the lower left with filtered hard rays. Both plants are greatly retarded in their growth. The plant radiated with hard rays is affected more deeply, and its tip is completely withered. Fig. 4 from O. Hertwig's article in P. Lasarus' book on "Radiumtherapie" shows two tadpoles. The smaller one shows an arrest of development produced by radiations.

It is probable that in complex vertebrate tissue the effect of a small amount of the rays also consists in an acceleration of the cellular functions. But it is difficult to demonstrate this phenomenon morphologically. Finally there takes place an inhibition of cell life. Different cells react differently to the rays. For instance, the liver cells are more susceptible to the rays than the gall-duct cells, and the tubules of the kidney react stronger than the glomeruli. Highly interesting is the action of the rays on the testicle and the ovaries The rays affect the spermatozoa forming epithelium and the Graafian follicles without influencing the other structural parts of the organs. As a result an azoospermia may occur in a man and a cessation of menstruation in a woman, by a quantity of the rays which produces no other abnormality in the organism.

Morphological Changes Induced in Tumors and Infectious Granulomata Under the Influence of Radiations.—It may be stated as a general rule that tissues of less differentiated, younger cells, cells in a state of active proliferation, are most deeply influenced by the rays.

Every tumor or granuloma consists of undifferentiated young cells in a state of active proliferation, and therefore a strong selective biological and consequently therapeutic influence of the rays on these conditions is the most evident. The morphological changes which take place in the different types of tumors and in granulomata under the influence of the rays differ to such an extent that it may be well to consider them separately.

Fig. 7.—Microscopical section of a sarcoma after treatment, showing connective tissue but no tumor cells.

Carcinoma.—The first morphological changes which occur in carcinomatous tissues under the influence of x-rays are observed in the tumor cells themselves and are manifested by the vacuolization of the protoplasm, pycnosis of the nuclei, caryoly-

sis, and complete necrosis of the cell. (Fig. 5.) All this is accompanied by a round-cell infiltration which replaces the destroyed carcinomatous cells. Somewhat later there begins formation of dense sclerotic connective tissue poor in blood vessels. This connective tissue formation may become very extensive, surround islands of carcinomatous cells, and assist in the destruction of the latter. The following case of carcinoma of the sigmoid, observed by the writer, with metastatic dissemination in the peritoneum which came to autopsy after six months of continuous *x*-ray treatment demonstrates the importance and extent of this connective tissue formation.

The patient died of acute intestinal obstruction. At the autopsy there were found in the peritoneal cavity several loops of the intestines adherent by old adhesions to the posterior surface of tumor mass in the sigmoid. The peritoneum, especially in the pelvis, was studded with numerous white plaques, varying in size from 1 mm. to ½ cm. in diameter; the larger ones were quite firm to the touch. Microscopical examination of a section taken through two loops of the small intestine which were firmly bound together by old adhesions showed that the adhesions consisted of a thick layer of connective tissue containing occasional nests of degenerated tumor cells. The peritoneal nodules were composed of dense connective tissue, with occasional groups of degenerated tumor cells. In the greater number of these nodules no tumor cells were found.

Sarcoma.—The morphological changes induced in sarcoma tissues by *x*-rays is analogous with those induced in carcinoma.

The following case of a giant cell sarcoma of the lower jaw, treated by the writer, illustrates this effect. A small piece was removed for microscopic examination before treatment, which showed a sarcoma with numerous giant cells and actively growing spindle cells. Following eight weeks of combined radium and x-ray treatment, another section was taken from the same region from which the previous one was obtained. The section showed a very loose connective tissue, relatively poor in cells, and beneath this a zone of denser connective tissue. No giant cells or any other form of tumor cells were present. Figs. 6 and 7 show the condition before and after treatment.

Infectious Granulomata, whether tuberculous, syphilitic, or of any other origin, as well as lymphosarcomata, are influenced by the *x*-rays in an identical manner. The lymphoid cells are destroyed and replaced by dense sclerotic fibrous connective tissue. A case of rhinoscleroma radiated by the writer shows the characteristic changes. Rhinoscleroma is an infectious granuloma, characterized by the presence in the granulation tissue of the so-called Mikulicz cells. The latter are degenerated lymphoid cells, enlarged in size, inside of which may be found frequently the Frisch bacillus, which is the causative agent. The microscopic examination after radiation showed that the granulation tissue was completely replaced by dense connective tissue. Figs. 8, 9 and 10 show the condition before and after treatment.

Thus the most generally observed morphological changes in tumor and granuloma tissue under the influence of radiation is the extensive formation of sclerotic connective tissue. Some observers maintain that this new connective tissue formation is the only direct effect of radiation. The destruction of the tumor cells is in accordance with this opinion secondary and due to lack of nutrition. This opinion cannot be accepted as true. In the first place, as was shown above, the first change noted in carcinoma is the destruction of the tumor cells and only subsequently does the connective tissue form. Moreover, in certain conditions, for instance, rodent ulcer of the skin, the epithelioma heals and is covered with skin without formation of connective tissue.

Other investigators assert that the destruction of the tumor cells is the only direct effect of radiation. The formation of connective tissue, in accordance with this view, is secondary to the accumulation of dead tumor cells and is analogous to formation of connective tissue around foreign bodies. This assumption is also hardly tenable. In the first place the amount of connective tissue formation in the peritoneal nodules of the carcinoma of the sigmoid reported above was entirely out of proportion to the number of carcinomatous cells destroyed. Moreover, if such young connective tissue were formed only by the stimulus of dead tumor cells, then the *x*-rays subsequently would dissolve this connective tissue as easily as it dissolves a keloid, for instance. But this does not take place and the amount of connective tissue usually increases, with subsequent radiation.

It must be concluded then that morphological changes which take place in tumors and granulomata under the influence of *x*-rays are two-fold. There occurs an inhibition and ultimate destruction of the tumor cells with irritation and consequent proliferation of surrounding connective tissue. The source of this new connective tissue is not the normal tissue surrounding the tumor. The postmortem study of carcinoma of the sigmoid reported above showed that there was no new connective tissue formed anywhere in the normal organs under the influence of radiation. The beginning of the new connective tissue must be looked for either in the stroma of the tumor, or in the round cell infiltration which always closely follows the destruction of the tumor cells by the rays.

It may be stated that the destruction of the tumor cells is the primary and the formation of new sclerotic connective tissue a secondary but as important a phase in the morphological changes which take place in tumors and granulomata under the influence of *x*-rays.

The Technique of X-ray Therapy.—Attempts at therapy by the aid of the *x*-rays began immediately after their discovery, but real progress in the matter was achieved not more than five years ago. It was then shown by French investigators and mainly by Gaus of Freiburg that the soft rays which constitute the major part of the beam of rays of an *x*-ray tube are absorbed by the skin, and that only the hard rays penetrate into the deeper tissues and produce there the therapeutic effect. Two methods have been gradually developed in order to obtain the hard rays. On one hand tubes used for therapy are the so-called hard tubes with a high vacuum, and on the other hand layers of metal are placed between the tube and the patient to filter off the softer rays. An additional filter of leather is placed under the metal to filter off the soft secondary rays formed in the metal filter.

Normal skin is highly sensitive to the action of the *x*-rays and a small quantity of even hard rays by far not sufficient to influence the tissues lying deeper underneath the skin may burn the latter. To obviate this difficulty another technical method is added which consists in using a number of small regions of the skin for the entry of the *x*-rays. These "fields" of the skin are so selected that the pencils of rays penetrating from any of them meet at the deeper lying tissues to be treated. This so-

called *cross fire* method increases greatly the quantity of the hard rays which may be employed without injury to the skin, since the combined quantity of the rays reaching the deep tissue equals the quantity penetrating through each field multiplied by the number of fields.

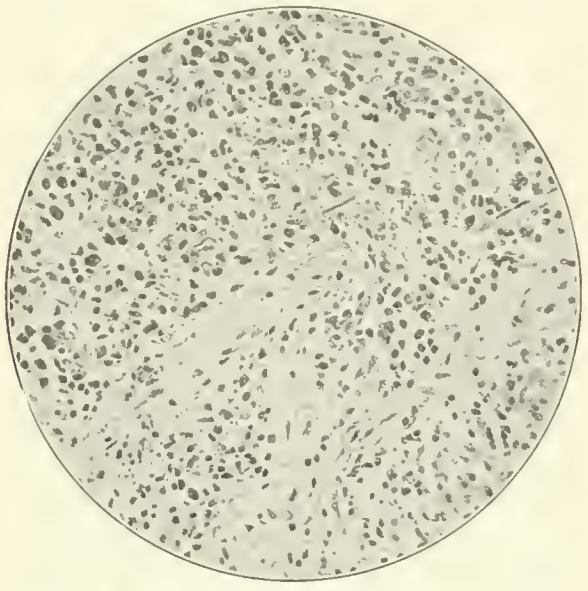

FIG. 8.—Microphotograph of a specimen of rhinoscleroma. Low power, showing granulation tissue.

The maximum quantity of *x*-rays which can be directed through the same field of the skin without injury to the latter is quite well ascertained. A very important phase of the modern methods of *x*-ray therapy is the great care exercised in measuring accurately the quantity of the *x*-rays employed. The measurements at our command are indirect and are based on the fact that the various chemical actions of the rays are in direct ratio to their quantity. A solution of barium platinocyanide, which has normally a green color becomes brown under the influence of the rays, and the shade depends upon the quantity of the rays used. A strip of photographic film wrapped in black paper and consequently impermeable to the rays of the light become darkened under the influence of the *x*-rays. The shade of darkening of the strip depends on the quantity of rays used. On the basis of these photochemical reactions, various apparatus are devised for measuring the quantities of the *x*-rays emitted by a tube in a unit of time. A unit is considered the quantity of the rays which produces an erythema of the skin.

The next important step in the progress of *x*-ray therapy was made by Coolidge through his discovery of the Coolidge *x*-ray tube. A brief comparative description of the old type and the Coolidge tubes will show the advantage of the latter.

X-rays originate on the surface of a metal which is bombarded by the negative electrons of the cathode rays. The greater the velocity of the cathode rays the harder, the more penetrating are the *x*-rays. The tubes of the old type have an incomplete vacuum. A high-potential current passes in the tube from the anode to the cathode, frees the electrons of the latter, and propels them toward the anticathode or target. The bombarding of the electrons induces the formation of the *x*-rays on the surface of the target. The target is built of a heavy metal and becomes overheated under the action of the cathode rays. The heat frees the gases contained in the metal of the target and these in turn diminish the vacuum of the tube. As a consequence the velocity of the cathode rays also diminishes and the *x*-rays become softer. Various regulating devices are added to the tube in order to keep the character of the *x*-rays uniformly hard for the length of time necessary for therapeutic purposes. Still the penetration of the rays emitted by the tube constantly changes. The most effective old-type tube is the one devised by Gaus of Freiburg for therapy. It has a water-cooling chamber to diminish the heating of the target, a large auxiliary vacuum bulb to diminish the influence of the gases freed from the overheated target on the combined vacuum, and a gas regulator to increase the amount of gas in the bulbs and diminish the vacuum when it becomes so high that no *x*-rays can be formed.

The fundamental advantage of the Coolidge tube consists in the fact that it has nearly a complete vacuum, so that the small amount of gas escaping from a heated target cannot influence it. Moreover, the target is built of tungsten which is completely freed of gas before the tube is finished. In such a tube with a complete vacuum, a high-potential current cannot pass from the anode to the cathode and free the negative electrons of the latter. The freeing of the cathode rays is accomplished in the Coolidge tube through the heating of the cathode to a high temperature by the aid of a special storage battery. The cathode consists of a spiral tungsten filament supported by a molybdenum sleeve. The high-potential current propels the freed electrons to the anode which acts at the same time as a target. The number of the electrons depend upon the temperature of the filament of the cathode and their velocity on the voltage of the primary current.

A priori it would be expected that the Coolidge tube would not only produce a greater output of *x*-rays, but also would generate rays of greater uniformity of penetration. Comparative experiments were done by the writer with the Gaus and the Coolidge tubes, using a very heavy German coil as a generator. Both tubes were placed approximately

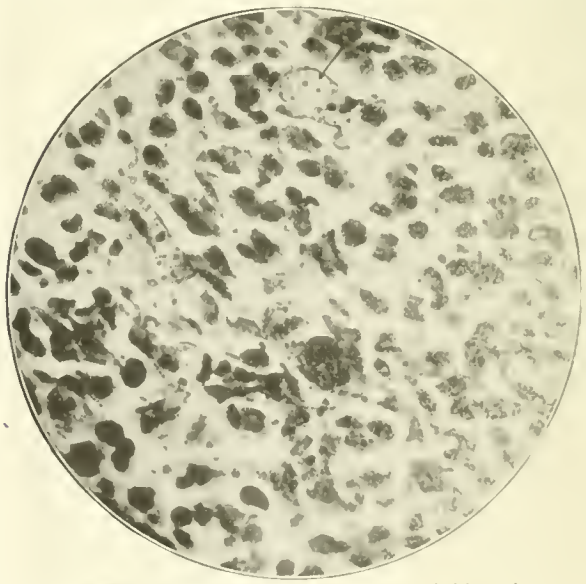

FIG. 9.—Microphotograph of a specimen of rhinoscleroma. High power, showing granulation tissue; *a*, Mikulicz cell filled with Frisch's bacilli.

under similar conditions, *i.e.* the same voltage of primary current was sent through the coil, nearly the same number of milliamperes of high-potential current was sent through the tube, and the resulting *x*-rays showed the same penetrating power.

To study the distribution of the rays, pieces of meat of certain thickness were radiated. Test strips of photographic paper (Kienböck strips) were placed on the surface of the radiated piece and at various depths of tissue. Pieces of meat were used 1, 1.5,, 2, 3, and 4 inches in thickness. The soft rays were absorbed by a plate of aluminum 3 mm. in thickness and a layer of chamois leather 2 mm. thick placed between the aluminum and the meat. Fig. 11 shows the records of two experiments: (*a*) an experiment with 4 inches of meat and a Gaus tube; (*b*) an experiment with 4 inches of meat and a Coolidge tube; (*c*) shows the Kienböck quantimeter and the method of estimation.

The results of numerous experiments may be summarized as follows: To obtain the same quantity of rays on the surface with a Coolidge tube takes about one-third of the time that was required with the old-type tubes. At the depth of 2 inches of meat the strip shows about one-third the quantity of the rays shown by the surface strip during the same experiment with an old-type tube and about one-half by the Coolidge tube. At a depth of 4 inches there is usually about one-seventh of the quantity shown on the surface obtained from a Gaus type, while from a Coolidge tube one obtains at the same depth usually one-fifth of the quantity shown on the surface. There is no complete regularity in the results of the experiments with either tube, but the Coolidge tube shows a far greater uniformity. The reason for this superiority shown by the Coolidge tube is probably due to the following: The *x*-rays emitted by a tube are never uniform in their character and represent all grades of hardness. The methods of measuring the penetration of the tube reveal only the hardest rays. Apparently the rays are more uniform in the Coolidge tube and a greater proportion of the pencil of rays are of the harder quality, and therefore a greater fraction of these entering the surface reach a certain depth. Another advantage of the Coolidge tube consists in the fact that when it is once regulated to a certain penetration it remains so for an indefinite period of time.

Therefore, when the same voltage (the same length of the parallel spark gap) and the same number of milliamperes of the high-potential is used in a Coolidge tube then there will also be generated the same quantity of *x*-rays in a unit of time, and the chemical measuring devices will show the same amounts and need be used only occasionally for control.

The technique of *x*-ray therapy employed by the writer at present is as follows: The Coolidge tube is used exclusively. The distance between the target and the skin is 8 inches and the length of the spark gap is 8½ inches. A Bauer penetrometer, an apparatus which measures the hardness of the rays, as well as the milliammeter are placed so that they can both be observed constantly through the lead glass window. The penetration or hardness of the rays is kept at 10 Bauer and 5 milliamperes are sent through the tube. Each field of the skin represents a circle of from 1 to 2 inches in diameter, depending upon the region treated. The rest of the skin of the patient is covered with lead rubber and the operator stands behind a lead lined booth, within which are placed all the electric controls. The walls of the treatment room are lined with one-eighth inch of lead to protect the operator, nurse, and the patients in the waitng rooms.

The Scope of X-ray Therapy.—It was stated above that the main physiological function of the *x*-rays consists in the inhibition of cell life. Furthermore a quantity of the rays which may be sufficient to inhibit a certain group of cells or a certain tissue or organ may produce no influence at all on the rest of the organism. These biological characteristics of the rays clearly indicate the scope of their therapeutic applicability. In tissue in which the main function of the cells consists in their proliferation, as in benign or malignant tumors or granulomata, an agent which kills the cells must of necessity at first arrest the growth of the tumor, and subsequently destroy it through the absorption of the dead cells.

When the cells are endowed with a special function, as in the parenchymatous organs, then the death of the cells will destroy or, if not all the cells are dead, will impede the function of the organ.

The chart presented below shows the diseases which are treated successfully by the aid of the *x*-ray, classified in accordance with the above-mentioned biological function of the rays. This classification of the diseases amenable to *x*-ray treatment indicates at the same time clearly the biological scientific basis for the inclusion of the *x*-rays in

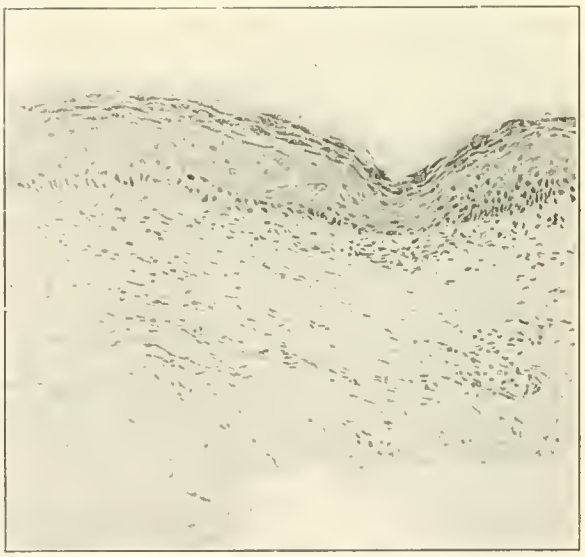

Fig. 10.—Microphotograph of a specimen of rhinoscleroma after treatment; the granulation tissue is replaced by dense connective tissue.

our therapeutic armamentarium. Indeed, the *raison d'être* of *x*-ray therapy is less empiric than of a number of pharmacological remedies.

Inhibiting Cell Proliferation.

Benign Tumors: Keloid, angioma, verrucæ, uterine fibroid, prostatic hypertrophy.

Carcinoma.

Sarcoma.

Lymphoma: Hodgkin's disease, mediastinal tumor, lymphosarcoma.

Granuloma: Tuberculosis of lymph glands, bones, joints; rhinoscleroma, inflammatory dermatoses.

Inhibiting Cell Functions.

Ovary: Metropathia, uterine fibroid.

Thyroid: Exophthalmic goiter.

Hypophysis: Acromegaly.

Thymus: Exophthalmic goiter, status lymphaticus.

Spleen and bone-marrow: Leucemia.

Below will be given a very brief review of the value of *x*-ray therapy in each disease enumerated in the chart. Good results are claimed by some

writers, in Addison's disease, sciatica, syringomyelia, and several other conditions, but they are omitted in this presentation and only such pathological conditions are analyzed in which there is sufficient biological and clinical evidence of the value of *x*-ray therapy.

Benign Tumors.—Keloid is readily influenced by *x*-rays. The hard red elevation over the skin disappears and is replaced by a white soft scar. In view of the fact that the keloid is situated superficially no crossfire method can be employed. The writer usually gives one full dose of hard filtered rays and repeats it every three weeks until the effect is produced.

Prostatic hypertrophy is treated successfully by *x*-ray as well as by radium, when the enlargement of the organ is due mainly to the hyperplasia of the glandular tissue. In cases in which the hypertrophy is due to an increase of the fibrous connective tissue the results are not so striking, but even in these cases the improvement of the subjective symptoms is very prompt. In view of the possibility of an occasional malignant degeneration of the hypertrophied gland and the splendid results of surgery, the latter method of treatment is always preferable in prostatic hypertrophy. On the other hand, whenever surgery is contraindicated *x*-ray therapy is the method of choice. *X*-radiation

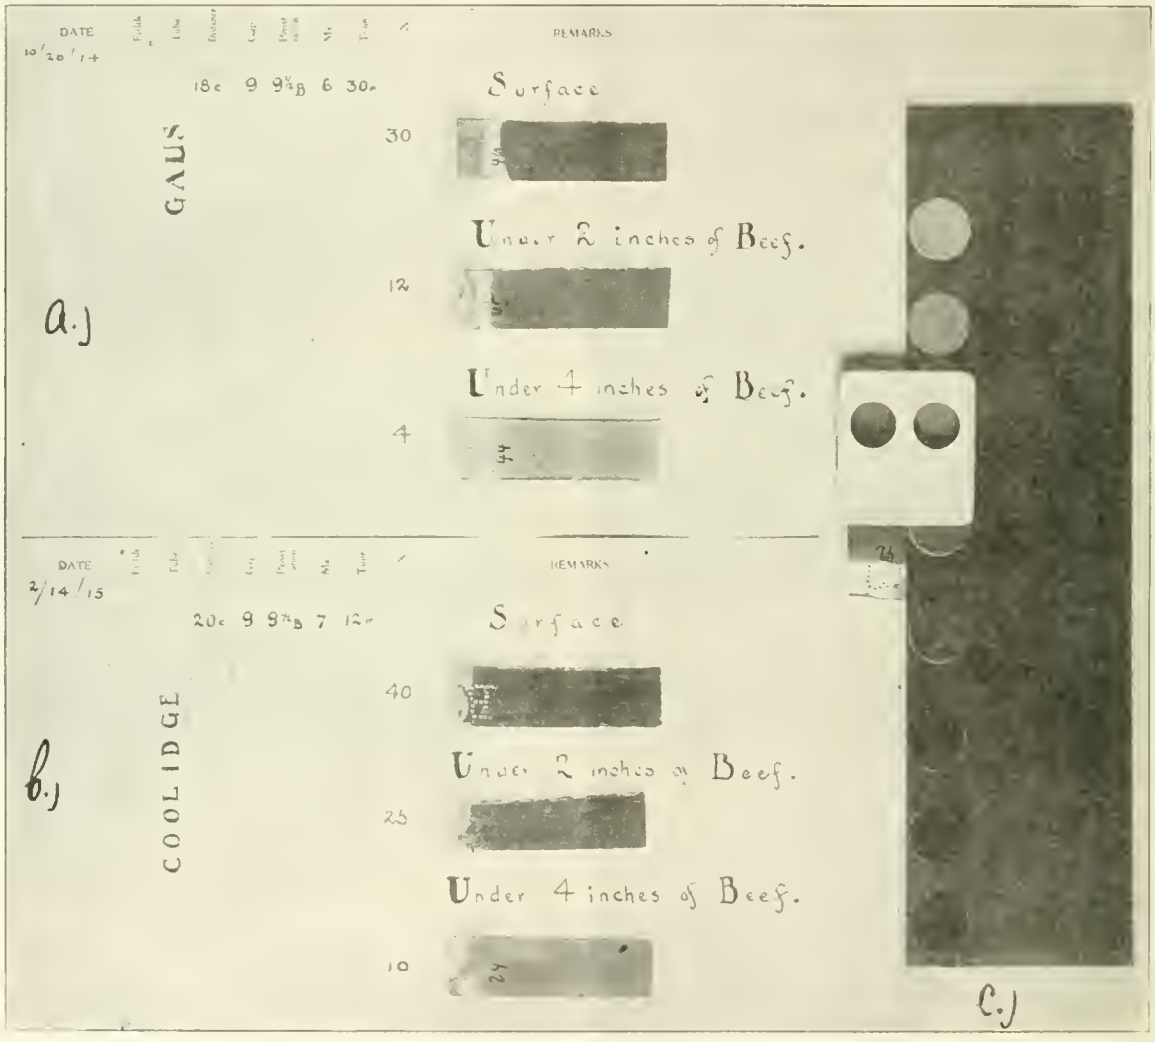

FIG. 11.—Record of two experiments—*a*, with a Gaus tube; *b*, with a Coolidge tube; *c*, shows the Kienböck quantimeter. The photographic slip is placed alongside a circle with the corresponding shade; the circles show the previously estimated number of units.

Angioma or nevus responds well to radiations when it is vascular and elevated over the skin. The so-called "port wine stains" are more refractory. *X*-ray treatment can be assisted by radium. In certain conditions radium is superior to *x*-ray treatment. Angioma and keloid are both influenced more rapidly by radium than by *x*-rays.

Verrucæ or warts disappear rapidly after two or three *x*-ray treatments.

Uterine fibroid is placed here because the *x*-rays produce undoubtedly a direct effect on the cells of the fibroid tumor and diminish its size. The main effect, however, is on the ovary and the subject will, therefore, be considered at greater detail in the section on inhibition of cell function.

is done through the suprapubic region and the perineum. The radiation of each field is repeated every three weeks, and the testicles are protected against the rays. Radium acts quite as well as the *x*-rays and takes less time. A radium tube is inserted in either the rectum or the urethra.

Carcinoma and Sarcoma.—It would lead too far afield to give here a complete exposition of the methods and rationale of *x*-ray therapy in carcinoma and sarcoma. Those interested should consult the previous publications of the writer on the subject. The best method of treatment of malignant tumors is undoubtedly the *combination of surgical treatment and radiotherapy.* The gross tumor should be removed surgically whenever pos-

sible, even when a radical operation cannot be performed, and the remnants of the tumor destroyed by radiotherapy. The writer has demonstrated anatomically that small islands of cancer tissue may be destroyed at a great distance from the skin; *i.e.*

Fig. 12.—Radiograph of a mediastinal tumor before treatment.

even a metastasis may be destroyed by *x*-rays when it is sufficiently small. In view of this the importance of the *postoperative prophylactic radiation* is self evident.

Postoperative treatment should be begun as soon after the operation as possible and regions should be selected for treatment in which the metastases most frequently occurs. For the same reason, *i.e.* in order to destroy small islands of tumor tissue at a distance from the primary tumor as well as to destroy *in situ* as many as possible of the cancer cells of the primary tumor every case should receive an intensive *x*-ray treatment before the operation. Such a course of treatment does not take more time than is needed to prepare the patient for the operation.

The *x*-ray treatment of malignant tumors must be very intensive, a great many fields of entry should be selected, and the raying of each field repeated at least every two weeks.

Lymphomata.—This class of diseases characterized by an enlargement of the lymphatic glands in various regions of the body responds promptly to *x*-ray treatment.

Hodgkin's disease or pseudoleucemia is a disease which resembles leucemia in many respects, only usually with a less prominent involvement of the spleen and no increase in the number of leucocytes in the blood. The affected lymphatic glands diminish very rapidly in size under *x*-ray and radium treatment, and with it there is a marked improvement in the general condition of the patient. The opinion seems to prevail that the action of the radiations is only palliative and that ultimately the patients fail to respond to the treatment. These unsatisfactory results are most probably due to the fact that *x*-ray treatment is attempted only late in the course of the disease and the treatment is not pursued with sufficient energy. The radiations should be given to many regions of the body not less than once a week for months, and only gradually should the interval between the treatments be increased. By this method the writer succeeded in early cases in arresting the disease for long periods.

Mediastinal tumors are most frequently lymphomata of the mediastinal lymphatic glands. The disease usually begins to give clinical symptoms only in its advanced stage, and therefore the results of the treatment are only temporary. Nevertheless, a number of cases were reported in which the *x*-ray plates show a clinical cure of the condition. The two radiographs shown in Figs. 12 and 13 picture a case of a mediastinal tumor under *x*-ray treatment by the writer. Fig. 12 shows the tumor before treatment, and Fig. 13 shows the condition practically cleared up nine months later.

Lymphosarcomata, or the round-celled sarcomata of the lymphatic glands, are not easy to distinguish from the above described lymphomata, but they usually tend to break through the glandular capsule and invade the surrounding tissue. Lymphosarcomata, while not as easily amenable to treatment as the lymphomata, respond easier than any other form of sarcoma.

Granulomata.—The therapeutic effect of radiations on infectious granulomata is not due as much to an influence upon pathogenic microorganisms as to an inhibitory action on the young cells of the granulation tissue.

Tuberculosis of the lymphatic glands gives the most satisfactory results of any form of tuberculosis. The clinical condition may be divided into three groups. Simple enlargement of the lymphatic glands promptly diminishes under radiation after an occasional initial enlargement. Ultimately the glands change into very small hard fibrous nodules freely movable under the skin. Glands with a central focus of suppuration should be treated after an aspiration of the pus or its evacuation through a small incision. In suppurating glands with open sinuses surgical treatment of the latter should accompany the radiation. It would lead too far to discuss here the respective merits of surgery and radiotherapy in the treatment of tuberculous lymph glands. It is quite evident that radiotherapy is a less severe method of treatment than surgery and is not followed by deforming scars and keloids. Moreover, if subsequently surgical removal should become advisable the preliminary radiation will simplify the operation by diminishing the size of the glands.

Tuberculosis of the bones, joints, and peritoneum is favorably influenced by the *x*-rays. The radiation should be employed either as an adjuvant to surgery, or when the latter is contraindicated. In all classes of surgical tuberculosis the local treatment with *x*-rays should be supported by a general radiation of the whole body, either by the direct rays of the sun (heliotherapy) or by the ultraviolet rays

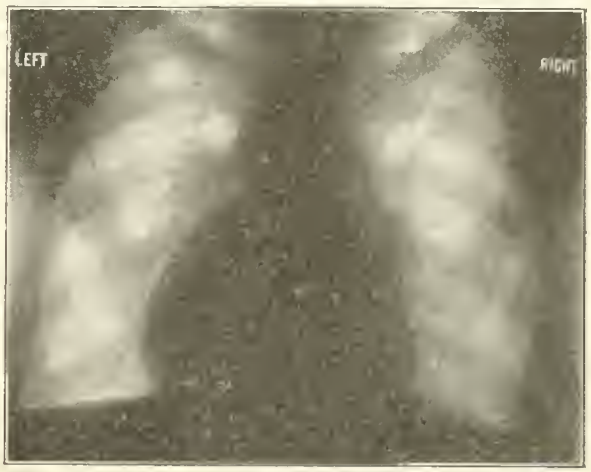

Fig. 13.—Radiograph of a mediastinal tumor nine months after the beginning of treatment; the condition is cleared up.

artificially produced by a quartz-mercury lamp.

Rhinoscleroma is an infectious disease characterized by tumor-like swelling of the mucous membranes of the nasopharynx, the pathology of which was described above.

The obstruction necessitates surgical removal of the swelling and the condition rapidly recurs after the operation. The tumors produce a swelling and deformity of the nose. Fig. 14 shows a photograph of a patient who suffered from rhinoscleroma for eleven years. She had to be operated upon with constantly increasing frequency, ultimately every month. She was treated by the writer with *x*-rays and radium and has remained well now for over two years.

The therapeutic action of the *x*-rays in infectious inflammatory dermatoses—psoriasis, eczemata, acne vulgaris, lupus vulgaris, mycosis fungoides—is very similar to its action in infectious granulomata. While all these skin diseases respond readily to *x*-ray treatment, all the other methods of treatment

Fig. 14.—Photograph of a rhinoscleroma patient, showing the characteristic deformity of the nose.

should be tried before radiation is attempted. Only in lupus vulgaris are the *x*-rays superior to any other method of treatment, and in mycosis fungoides they act like an actual specific. There has been a great deal of controversy recently in regard to comparative merits of the soft and hard rays in the treatment of skin diseases. The writer finds the hard filtered *x*-rays just as efficient in skin lesions as for deep therapy.

Ovary.—Uterine hemorrhage and fibroid uterus. The efficacy of *x*-ray therapy in these conditions has been proven on hundreds of cases. The action is due mainly to the inhibiting influence of the rays on the ovaries, causing thereby an artificial menopause. Moreover, as stated above, the *x*-rays have undoubtedly a direct effect on the tissue of the fibroid tumor, destroy most probably its younger cells, and thus diminish the size of the tumor. In women near the natural menopause the result is both prompt and lasting, the bleeding ceases, and with it the other symptoms. In at least half of the fibroid cases the tumor itself diminishes occasionally to such an extent that the size of the uterus becomes nearly normal. In young women the treatment is not nearly as successful, and it is difficult to obtain a complete menopause. Still the bleeding decreases so that the menses become normal, and the size of the tumor is diminished.

In uncomplicated conditions of climacteric metrorrhagias and fibroids radiotherapy is fully as efficient and by far less dangerous than the operative treatment and therefore *x*-ray therapy is the method of choice. It is contraindicated in young healthy women in whom there is a possibility of performing a conservative myomectomy without removal of the ovaries.

Fibroids complicated by diseases of the adnexa, or by the coexistence of a carcinoma or a sarcoma of the uterus demand operative interference. When the malignancy complicating the fibroid is inoperable radiotherapy again becomes the method of choice.

The possibility that a radiated fibroid uterus may become subsequently sarcomatous is very slight, since a true degeneration of a fibroid into a sarcoma is found in less than ½ per cent. of the cases.

Thyroid.—Exophthalmic goiter is promptly influenced by the *x*-rays in a great percentage of the cases. Of the symptoms of the disease the pulse rate is the first to respond most easily to the treatment, next the weight increases, and the sleeplessness, and the other nervous symptoms show a great improvement. The exophthalmus and the goiter are the last to be influenced and in a certain number of cases these last two symptoms remain unimproved. A preliminary radiation does not make a subsequent operation more difficult. In view of all this, no case of exophthalmic goiter should be operated on without an attempt at *x*-ray therapy.

Thymus.—The thymus is found to be enlarged in the majority of cases of exophthalmic goiter. In these cases the symptoms may be due to a great extent to the enlarged thymus. This organ diminishes in size very rapidly under *x*-ray treatment, therefore cases of exophthalmic goiter accompanied by an enlarged thymus are readily influenced by radiation, while the surgical treatment may remain without effect.

Status lymphaticus is a clinical condition which is due mainly to the enlargement of the thymus and may also be very favorably influenced by *x*-ray treatment of the gland.

Hypophysis.—In view of the brilliant results obtained by *x*-ray treatment of the thyroid and the thymus in exophthalmic goiter it seemed reasonable *a priori* to expect that in acromegaly the raying of the hypophysis may benefit the disease. Indeed, there are reported in the literature a few cases in which the *x*-ray treatment exerted undoubtedly beneficial effect on the disease.

Spleen and Bone-Marrow.—Leucemia is a disease in which the characteristic changes are an alteration in the relative proportions of the different leucocytes of the blood, with an increase in their number, and the appearance of unusual forms. The red cells are diminished in number, abnormal forms appear in the blood, and accompanying these alterations in the blood are changes in the spleen, bone-marrow, and in the lymphatic glands. In myelogenous leucemia the changes are mainly localized in the spleen and the bone-marrow, and the blood

shows an increase in polymorphonuclear leucocytes and in myelocites. In lymphatic leucemia all the lymphatic glands are enlarged as well as the spleen and there is an increased number of lymphocytes in the blood. The disease is analogous in many respects to lymphosarcoma and may be considered to be a malignant disease of the blood. The readiness with which this disease responds to *x*-rays is quite remarkable. The leucocytes after a slight initial increase promptly diminish in number. The following observation made by the writer in collaboration with Dr. B. Joseph is very interesting in this connection. While the number of myelocytes in myelogenous leucemia may decrease to a remarkable degree after a few *x*-ray treatments, the increased number of myelocytes found in cases of skeletal metastases of carcinoma remain uninfluenced by radiation. The spleen as well as the lymphatic glands decrease in size and the general condition of the patient improves. In regard to the ultimate result, and the relapses of the disease, the statement made above in connection with Hodgkin's disease may be repeated. The earlier the treatment is begun, and the more energetically it is pursued, the longer will the life of the patient be preserved. The radiations with hard filtered rays should be given not only over the regions of the spleen, liver, and the lymphatic glands, but also over the regions of the long bones. For several years the treatment should be repeated at stated intervals. The treatment should be controlled constantly by blood examinations.

Conclusion.—The difference in the technique and the armamentarium used in radiography and in *x*-ray therapeutics is very considerable. Each of these two modes of the medical application of the *x*-rays have extensive fields of usefulness of their own, and it would be most advantageous for the progress of both disciplines if they were not united in the same laboratory. Each worker should develop only one branch of the work. The great success of radiotherapy in Germany dates from the time when the surgeons and gynecologists themselves undertook this method of treatment instead of referring the patients to the radiographers. Correct radiotherapy implies a thorough understanding of the pathological and clinical condition of the patient as well as the technique, dangers, and limitations of the therapeutic measure.

As shown above, the usefulness of *x*-ray therapy is limited to a well-defined class of diseases, but in those it acts very frequently as an actual specific and always as a very important adjuvant to other methods of treatment. It behooves as little the clinician to neglect this method of treatment as the *x*-ray therapeutist to become over enthusiastic

THE WORTH OF AN EARLY *X*-RAY EXAMINATION IN GASTRIC CANCER.

By GEORGE M. NILES, M.D.,

ATLANTA, GA.

The Roentgen ray as an early diagnostic agent in suspected or non-suspected cases of gastric cancer has won a recognized rank.

Many and erudite have been other methods advanced; and for some of the newer processes, such as the glycyltryptophan test, the phosphotungstic acid reaction of Wolff, the hemolysis test, and the modified Abderhalden reaction, glowing claims have been put forth. Unfortunately, all of these have been weighed and found wanting in some particular, and thus two hapless conclusions are forced upon us: first, that a reasonably early diagnosis of gastric cancer from clinical data alone is

Fig. 1.—Malignant infiltration of the pylorus. This patient has had superficial epitheliomas removed from lip and nose; resection advised.

impracticable; second, that when a clinical diagnosis of such can be readily made, the patient may well set his earthly affairs in order, for no form of therapy is then of permanent service. With the Roentgen method, however, we have a means at hand, which, if carefully employed and intelligently interpreted, will prove itself worth while in detecting early carcinoma.

Another important possibility of a Roentgen examination is the recognition of a latent, but perhaps advanced, cancer with few or no special symptoms.

Apart from pyloric obstruction, the diagnosis of carcinoma depends upon irregularities in contour caused by the inroads of the growth. These may be quite small, like the outline of a piece of coral, or there may be more or less marked obliteration of the cavity by the growth, which displaces the barium, causing a distortion of the normal shadow. Viewed through the fluoroscopic screen, these inroads may suggest peristaltic waves at first sight, but, on closer observation, it will be noted that they

Fig. 2.—So-called "leather-bottle stomach." In this condition there remains only a rigid tube through which the nourishment flows out almost immediately; inoperable condition.

are permanent, that the peristaltic waves sweep up to these notches, are lost to sight, then reappear on the further side of them. In advanced cases the major part of the stomach cavity may be completely obliterated, showing an irregular shadow

that possesses no likeness to a normal gastric contour. Growths invading the anterior or posterior walls are sometimes so arranged that the barium is displaced and a clear space observed in the midst of the shadow. These clear spaces may appear and

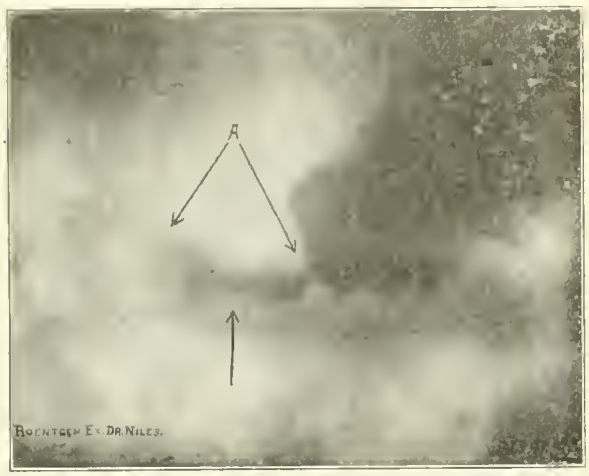

FIG. 3.—Annular carcinoma involving the pylorus and greater curvature of the stomach. Note the "bitten-out" appearance of the greater curvature; inoperable condition.

disappear as the peristaltic waves sweep on, and the gross aspect may sometimes be completely altered by palpation. Particles of retained food which have been coated over or admixed with barium may cause confusing shadows, so it is well to obtain roentgenograms on successive days to guard against this error.

Adhesions in the vicinity of the stomach, pylorus, or duodenum may also cause inroads that are difficult to differentiate from neoplastic growths; and such problems can only be intelligently solved by combined palpation under the screen and a liberal number of roentgenograms.

Spasmodic contractions may counterfeit growths, calling for gentle massage under the screen, plus a subsequent examination. Let it be insisted upon that there is seldom a case in which a *single* examination justifies an absolutely positive diagnosis with its perhaps somber prognosis.

The technique in the Roentgen investigation of these cases is quite similar to the routine examination in other lesions of the stomach. The writer uses buttermilk (about 12 ounces, if that much can be retained) and barium (about 2½ ounces). Several plates are made at once both in the standing and prone positions. Sometimes plates made in the

FIG. 4.—Artist's drawing of Fig. 3.

lateral or oblique positions afford valuable information. Let this be clearly understood—a single plate showing a normal filling may carry more diagnostic weight than a dozen which fail to fill.

A few neoplastic growths occur in the cardiac region of the stomach, usually invading the cardiac orifice. Such patients generally come for obstructive symptoms, refereable to the esophagus; and in many of these it is found that the carcinoma has already reached the inoperable stage. In the

FIG. 5.—Extensive involvement of pylorus and prepyloric region. The symptoms appeared suddenly in a very robust man; condition inoperable.

writer's experience no carcinomatous invasion of the stomach is more insidious than that situated near the cardiac orifice.

Primary carcinoma in the pars media is a rare entity.

Filling defects at or near the pylorus are annular in character, lending the appearance of an unduly elongated pyloric gap. This *annular* aspect is not so clearly noted in chronic ulcer. As before mentioned, these apparent lesions should be verified by a number of plates with the patient in varying postures. Should the annular appearance be corroborated by bitten out "notches," the examiner may be nearly sure he is dealing with a *growth*.

It little matters whether the neoplasm is primary or a malignant degeneration on the site of an old ulcer, the potentialities for evil are the same. When such material conditions are obvious, and are proved by a painstaking Roentgen investigation, immediate and radical surgery should be recommended.

Negative findings are of great value only when the examination has been thorough. A normal-appearing shadow of the stomach with a smooth and unserrated contour rules out any neoplasm be-

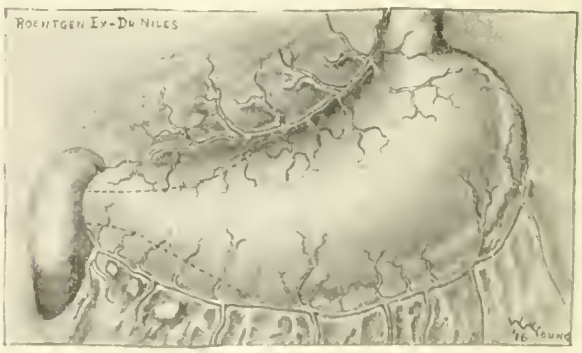

FIG. 6.—Artist's drawing of Fig. 5.

yond the microscopic stage. In a few instances under the writer's observation, a careful examination. Roentgen and otherwise, with unmistakable negative findings has *cured* the patient.

In some late cases so much of the stomach struc-

ture may be involved that there seems to be simply a rigid canal with no peristaltic waves whatever. The patient can take only a small amount at a time, thus running out of the stomach almost as rapidly as it descends through the esophagus. Unless the plate is taken expeditiously, the stomach will have emptied itself so that no shadow will be discernible. Such a case is shown in Fig. 2.

In conclusion, let it be asserted that when any individual in middle life rather suddenly develops indigestion, when this indigestion cannot be satisfactorily explained by abnormalities of the circulatory system, the kidneys, the blood and blood-forming organs, or the central nervous system, a careful roentgenological examination is emphatically indicated. Otherwise, many guileless patients and over-optimistic physicians will wake up to a sudden realization that the "day of grace" has passed, and that the malignant process has overspread operative bounds.

COMPLETE TRANSPOSITION OF VISCERA, WITH REPORT OF TWO CASES.*

By H. J. HARTZ, M.D.,

PHILADELPHIA, PA.

Of the abnormal positions of the viscera the most important is the one known as "situs viscerum inversus" or lateral transposition of the internal organs; the transposition forming a mirror-image of the normal. The transposition may be complete or partial. If restricted to the heart alone the condition is known as dextrocardia. In rarer instances the change involves only the abdominal organs.

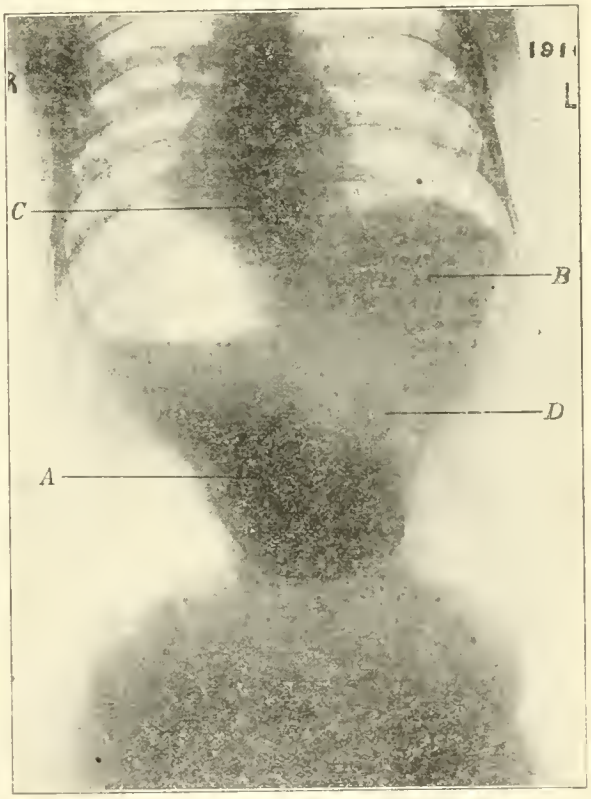
The various theories explaining the development of the viscera are chiefly of interest to the embryologist and anatomist. Adami[1] believes that the most likely explanation is that the main current of blood to and from the germinal area becomes diverted at an early stage of existence and thus purely mechanical influences lead the vessels of one side of the organism to receive more blood and therefore to grow more vigorously than those of the other. There are numerus other theories relating to this subject but they are too technical to be discussed in a paper of this kind.

Cases of partial transposition are not as common as the complete type. Lochte,[2] in 1898, was able to collect but 13 cases of this incomplete variety.

To the clinician transposition of the viscera presents many interesting problems in differential diagnosis. Congenital displacements of the heart to the right must be differentiated from those occurring in disease. The acquired displacement of the apex beat occurs rarely beyond the right mammary line. It may be caused by the pressure of a left-sided pleurisy with effusion, a left hydrothorax or pneumothorax, a tumor of the left lung or mediastinal tumors. It may be caused by the retracting power of chronic fibroid changes in the right lung and adhesions in the right pleural cavity which fix the heart in this abnormal position. The discovery of an enlarged area of dullness in the left hypochondrium is suggestive of several conditions. Besides a transposed liver, an enlarged spleen either of leucemia, malaria, or splenomegaly may be present. The dullness may be caused by an enlarged movable and prolapsed kidney or perinephritic abscess. Fecal accumulation, effusion in lesser peritoneal cavity, a subphrenic abscess, psoas abscess, cancer of splenic flexure of colon, and tuberculous peritonitis must also be considered.

In 1865 Gruber[3] made an exhaustive study of the literature and collected 79 cases of complete transposition of viscera; Küchenmeiser,[4] in 1883, added to that series and increased the number to 149. In 1895 Pic[5] reported 190 cases, which number represents all of the cases known in literature up to that year. Arneill,[6] in an elaborate study in 1902 involving communications with leading internists and anatomists, reported over 40 additional cases.

In this country, cases of transposition in recent times are much more frequently discovered during life than on the post-mortem table. Arneill contrasts Gruber's series and his own. Of the 79 cases reported by Gruber only five or six were discovered during life. In Arneill's collection, which numbered 44 cases, 38 were diagnosed during life, and but six after death.



Case I.—*X*-ray photograph of patient, standing erect, taken in anteroposterior position after a bismuth meal. *A*, stomach on right side of median line; *B*, liver on left side of body; *C*, heart displaced to right of median line; *D*, duodenal cap displaced toward the left.

Gruber in his study arrived at a number of interesting conclusions. There were 49 men, 19 women and 11 in which sex was not mentioned. The longevity in these individuals did not differ from those with normal organs. The women were normally fruitful, one gave birth to 12 children. In 71 of the 79 cases both chest and abdominal organs were displaced. Of the abdominal organs alone there were 8 displacements. Lungs were transposed in 35 of 71 cases, the right had two lobes and the left three lobes.

Case I.—The case that I am reporting is that of a boy 13 years of age, name S. F., white American born of Hebrew parentage. Has one sister 15 years old and one brother 11 years old. The family history is negative. Had measles and chicken pox in infancy, otherwise has enjoyed perfect health.

I was called to the patient's home and found him complaining of pain on left side of chest in midaxillary

*Read before Jefferson Hospital Clinical Society, January, 1915.

line, aggravated on deep inspiration and during coughing; duration one day. Physical examination showed a well-developed muscular and robust boy. On examining the bared chest I was surprised at the absence of the cardiac apex beat from its usual location. The heart was completely transposed to the right side of the body with apex in the right mid-clavicular line. The lungs were normal except for a slight pleural friction rub in midaxillary line on left side, ascertainable both on palpation and ausculation. Liver dullness was outlined on left side of body and the stomach was transposed to the right of the midline. The right testicle was at a lower level in the scrotum than the left. The patient was right handed. In a few days the patient recovered from his pleurisy. Fluoroscopic and *x*-ray studies were made following ingestion of a bismuth meal, and verified the physical findings of a complete transposition of all of the viscera of the chest and abdomen.

That complete transposition of viscera is not an infrequent condition is evidenced by the fact that quite recently (November 22, 1916) I had the good fortune of discovering a second case of this interesting anatomical anomaly.

Case II.—I was called to the home of a little patient that was complaining of a sore throat. The following history was elicited: The patient D. S., is a boy 12 years of age, American born of Italian parentage. During childhood had frequent attacks of tonsillitis, otherwise has enjoyed fair health. The present illness consists of an acute attack of follicular tonsillitis, superimposed on a chronic hyperplasia of tonsils. The boy is fairly well developed but rather slender for his age. In view of above history I was anxious to know if cardiac murmurs existed, and on examining the chest I located the apex in mid-clavicular line on the right side, the liver dullness was elicited on left side of body, the stomach was to right of median line. Fluoroscopic and *x*-ray examinations following a bismuth meal showed a complete transposition of viscera. The plates were practically identical with those of the case reported above.

DIVERSIONAL THERAPY IN MENTAL DISEASE.

A PLAN FOR ITS EMPLOYMENT WITH SPECIAL REFERENCE TO SOCIAL CLUBS.

By LEIGH F. ROBINSON, M.D.

RALEIGH, N. C.

PHYSICIAN IN CHARGE FEMALE DEPARTMENT STATE HOSPITAL.

The treatment of mental disease by diversional therapy has been recognized for some time to be the most rational and scientific. The method is one of substitution and is accomplished by replacing the focal idea of consciousness. For if a healthy idea can only occasionally be substituted for an idea of false reasoning the patient's attitude of mind and conduct will improve. Considering the psychology of diversional therapy, let us suppose a group of patients manifesting different forms of insanity are attending a moving picture show, we are impressed how well their attention is held. Suppose another group are attending a dance, and observe how interested those become who are fond of dancing and what a good time they have. There is another group employed in some useful mode of occupation, we again are impressed with the interest one manifests who is weaving a rug or another occupied in the construction of a table. And so we could suppose ourselves conducted throughout an average hospital for the insane and invariably observe that those patients that seem to derive the greatest benefit from their employment are those most interested in their work and who accordingly give to it a more undivided *attention*. This would bring to mind a well-known fact that the attention is dependent upon the emotion and controlled by a motor mechanism which is inhibitory in character. In other words, anything capable of engaging the attention must first to some extent stir the emotions. This requires a quality of attractiveness. Recognizing such principles, diversional therapy is employed to render those things attractive that are not naturally so and in like manner produce an interest in them.

The different psychoses will be touched upon in so far as the treatment of them is related to diversional therapy. First, manic-depressive insanity; in the depressed form of this psychosis the patient has his inhibitory powers of attention increased. Here the mind is obsessed with fixed ideas that are delusional in character and tend toward more or less dangerous acts of conduct. In such cases diversional occupation of the mind will help to crowd aside the false beliefs. In the other type characterized by increased psychomotor activity and flight of ideas, the attention has become greatly debilitated. Patients suffering from this type may have the excess energy utilized through occupation.

Second, in those psychoses characterized by mental enfeeblement and dissociated personality, namely, the precox group, diversional therapy tends to dissolve the symbolical personality and arrest mental deterioration. The process by which this is accomplished is best explained by comparing it to a boy flying a kite, the boy representing the patient, the kite his mind soaring afar off in its world of fantasy and the string diversional therapy which serves as a means to prevent the mind's complete withdrawal or at least retard the usual rapid dementia characteristic of this type of insanity.

Third, the use of diversional therapy in the functional group of psychoses yields remarkable results toward directing the stream of thought into healthier channels.

Fourth, there is that large group of dements and aments who show slow reaction to external stimuli that may be brought out of their lethargy through re-education.

In the prescribing of diversions the same care should be observed as when drugs are used. There is danger of overtaxing the patient's strength and causing him to become disinterested through a lack of variety or too long hours and not enough recreation. Patients will soon grow weary of "all work and no play." In view of this fact, care must be taken to have work and recreation balance well.

In order to schedule new patients correctly, we follow a regular routine in the keeping on new patients what we call an "Efficiency Report" which gives a full report on personal, social, and industrial capacities and incapacities as observed by

nurses and physicians. This report is completed at the end of the second week subsequent to admission. A monthly record is kept of the hours patients are employed and entertained. One record is kept by those in charge of the department in which patients work. The nurses on the wards keep three records, one for the patients who are employed about the wards, a second in which is kept a total of the hours each patient on the wards is employed, a third in which is kept an account of the number of hours the patients are entertained. These reports give to those in charge a correct account of the work each patient does in the different departments. The second report kept by the ward nurses gives a check upon the records kept by outside department heads, who as a rule are careless in keeping correct reports of patients. The third enables us to balance up productive employment and recreation received by each patient.

It is doubtful if it is a wise plan to give other rewards than tobacco. At some places, patients are allowed both smoking and chewing tobacco. Requisition should be made for tobacco in the form of snuff and plug on approval of physician in charge for whom it is wanted. It should be given out in morning daily allowances when the patients are leaving the wards for their various places of duty. There is no one thing that gives patients so much pleasure as the permission to use tobacco, and no special privilege that will give the work more attraction.

Below, I submit a plan for a department of diversional occupation and have tried to observe the principles of variety and balance between productive employment and recreation. In the productive group, there are included the different industries and the farm upon which an institution's momentum and upkeep partly depend. There is also included in this group a number of diversions that are productive through the manufacture of materials which are exportable. In the second group, designated nonproductive, we have in mind the employment of those patients whose conditions do not allow them to enjoy the freedom of those who work in the productive group; that large class of patients that are more or less disturbed and demand special attention by the attendants and nurses. This is the most important group since here the greatest amount of good by diversional therapy can be obtained. In this division the patients may be occupied with raffia, basketry, pottery, and hand weaving which are all good in holding the attention of the patients. At the Taunton State Hospital, Miss Cameron, Superintendent of Nurses, uses a method by which she teaches a class of nurses a new idea which the nurses each in turn teach to a group of patients. In the third group designated recreation the different forms of entertainments and athletics are included. The scheme of this plan is as follows:

A. Productive Employment.
   1. Industrial: (*a*) Shops, including sewing rooms, mending rooms, shoe repair, carpentry, laundry, etc.
   2. Farm and Garden.

B. Non-Productive Employment.
   1. Ward classes.

C. Recreation.
   1. Athletics: (*a*) Gymnasium; (*b*) Athletic field, providing tennis courts, ball diamonds, football and basket ball.
   2. Entertainments, including special lectures, moving pictures, dances and entertainments by patients.
   3. Devotional.
   4. Library.
   5. Social Clubs.

The department as outlined above, I believe, should be under the direction of the superintendent of nurses, as carried out in the Taunton State Hospital at Taunton, Mass. We have accordingly placed this department under the superintendent of nurses. Each group is headed by a Supervisor who is directly responsible to her.

The supervisor of the farm and garden work parties sends out daily patients as directed by the medical department to the different places where their labors are needed. He visits the patients at such places, looking after them in regard to their comforts, reporting those to the physician who require attention. He also makes requisitions for tobacco and proportions the same to the attendants of work parties.

The patients working in the laundry and shops are under the direction of the department head who is responsible for them and reports any irregularities to the assistant physician or superintendent of nurses. In this department, as in the farm and garden department, tobacco and snuff is requisitioned for by the supervisor of industrial department and dealt out by him to the patients. The second group of nonproductive employment has already been described.

The third group, recreation, takes up first athletics, which includes in addition to the gymnasium all outside athletics. One understanding the principles of physical culture should be in charge of this division. The physical director should provide during the winter months every evening some form of entertainment for a part or all the patients. There should be for every day a regular schedule of classes, made up of those patients who are included in the productive and non-productive groups. During the summer months special attention should be directed toward the athletic field, which should provide tennis courts, ball diamonds, football and basket ball. The physical director should teach the patients how to play different games, doing so by regular classes. Frequent games between patients should be arranged and games with outside teams encouraged. It must be remembered that not only those who attend the classes and take part in the games derive benefit from the athletic department, but those who are spectators at the games which includes a very large number, since all the patients who can should be permitted to go.

Second, we come to that part of recreation which includes special entertainments, lectures, moving pictures, dances, and entertainments given by patients. Frequent entertainments impromptu in character should be arranged for the patients; they may consist of sleight-of-hand performance and the like, and if the institution is in a large city a number of entertainments can be provided by the inhabitants, who as a rule will be glad to assist in such work. Special lectures on interesting subjects and story telling provide good means for entertainment. Dances and moving picture shows should come regularly and frequently.

Third, in this division we come to religious services, in which we include such services as conducted by ministers and others of the pulpit and the singing of religious songs. These services cannot come

too often if conducted properly. Here we have three services on Sunday, morning, afternoon, and evening. The evening service is nothing more than the singing of hymns, but it enables us to provide all of the patients with at least weekly attendance. It is a good routine to request of those in charge of such services to be careful not to use any discourse that tends in the slightest degree toward emotionalism. The same thought should be borne in mind in the singing of religious songs, only those hymns that tend neither to depress nor to excite the emotions should be sung. The books used should have those songs checked that have been approved by the medical department.

Fourth. The library should be sufficiently large for the requirements of both patients and employees, and should be under the supervision of a librarian who keeps similar records in regard to books and the loaning of them as in any public library. The patients, in the attendance of nurses, should be allowed certain hours to go to the library and select the books they wish to take. A certain schedule should be followed in regard to taking patients in classes to the library where they can read the papers and magazines provided there.

Fifth. In this division I will describe a plan by which social clubs organized among patients will bring remarkable results. A number of state hospitals have organized such clubs and found them very productive. I have organized among the patients in the female department a large number of clubs, namely, reading circles, musical clubs, dramatic clubs, card clubs, sewing circles, etc. These clubs are organized with a limited membership, and all meet at least once a week. Each club elects its own officers, consisting of president, vice-president, and secretary. The officers and members are given the privilege of conducting the clubs as they desire. A nurse designated as advising officer meets with the club and tactfully stimulates its progress. Patients vote on new members by secret ballot, and the names of those that are accepted are submitted to the assistant physician for his approval. Each member wears a badge which bears the name of the club, for example: "Monday Afternoon Sewing Circle." I find the patients are very proud of the badges, which I believe have a greater stimulating effect than anything else. One of the parlors of the administration building is provided for holding some of the meetings. Refreshments are served at each meeting in the form of tea, wafers, fruit, or ice cream. Picnics are voted for occasionally and because of their beneficial results are granted whenever possible. Outsiders are urged to visit the clubs but I have them obtain final permission from the president of the club which they wish to visit. This adds dignity and to the patients increases the clubs' importance. The visitors are asked to enter into the work of the meeting exactly the same as they would do if visiting a club in a community of normal individuals. Too often persons with best intentions when visiting mental patients are prone to show unwanted sympathy and unconsciously exaggerate their own normal condition.

The sewing circles do principally fancy work, and the members take great pride in learning new things and teaching the same to new members. Outside visitors come, and while they are requested at least to pretend to receive more than they give, they frequently interest the circles with something new. The card clubs meet in the evening, play the usual games and enjoy the refreshments very much. Every floor and building has a reading circle named after its respective floor or building. These circles meet in the evening and read aloud interesting articles in which the advising nurse assists. Magazines and books are sent to the Hospital by a number of its friends and are distributed to the different circles for their use. One of the clubs has the distinction of having given interesting entertainment every week since its organization eight months ago. Officers, employees, and outsiders have been in regular attendance and always report a good time. The dramatic club gave a play this Spring for the graduating class of the Training School, and it was considered by everyone to be equal to the average amateur play.

Personally, I am very enthusiastic about this phase of diversion and believe that social clubs tend to give to the mental patient his former adjustment more rapidly than any other. Of course, they should be conducted properly and the principles adhered to which I have brought out above, namely:

First, give patients, as far as possible, full charge of the clubs which they compose.

Second, keep up an interest by not allowing the object of the club to diminish in its importance.

Third, serve refreshments at the meetings and if at all possible grant picnics and special privileges whenever such are requested.

Fourth, provide badges which not only increase the interest but create pride in the wearer.

Fifth, encourage officers and outsiders to attend the meetings frequently, but never allow visitors to forget that they are objects of the club's hospitality.

NAUSEA AND VOMITING AFTER NITROUS OXIDE-OXYGEN ANESTHESIA.

By WILLIAM L. SOULE, M.D.,

NEW YORK.

ANESTHETIST, CORNELL DIVISION, NEW YORK HOSPITAL.

THE opinions of the average medical man on any unsettled question may be derived from impressions—his own and those of other men—from experimental evidence, from statistics, or from the statements of recognized authorities. Though it is not scientific to rely upon impressions, many conclusions are arrived at in this way and sometimes they are more correct than those based on experimental evidence and statistics. Experiments are often faulty, statistics are fallacious, and both may be wrongly interpreted.

The status of gas oxygen anesthesia may be regarded as not entirely settled, and, as members of the medical profession have had varying impressions and experiences in connection with its use, opinions naturally are divided.

The writer's first experience with nitrous oxide was obtained in a hospital where a large amount of tooth-extracting was done under this anesthetic. The gas was pushed till the appearance of cyanosis and stertor, then the inhaler was removed and the extraction rapidly performed. The anesthetic was considered so safe that we never thought of any danger and vomiting was very rare. Several years later the writer saw, for the first time, a major operation (prostatectomy) performed under gas-oxygen with ether as needed. The cyanosis, which was exhibited to a considerable extent, was not unexpected, but the vomiting which followed the withdrawal of the anesthetic was something of a surprise and gave rise to the question whether ether

alone would not have done as well. Subsequent experience and conversation with other observers frequently suggested the same question. It was disappointing to find that after this form of anesthesia patients frequently vomited — especially women. The vomiting, too, seemed to take place irrespective of preliminary morphine medication or the addition of ether or of skill (or lack of skill) on the part of the anesthetist.

For example, one patient, who received a preliminary hypodermic of morphine and was under the anesthetic for a few minutes while the uterus was curetted, remained apparently unconscious for half an hour or more after the operation and suffered from nausea for several hours afterward. Another patient without preliminary medication took her anesthetic very satisfactorily for six minutes while some necrosed bone was removed from the os calcis. She vomited at the close of the operation and was more or less nauseated for several hours. No ether was used in either of these cases. Two patients, operated upon within a few days of each other, were of particular interest because of the striking points of contrast which their cases presented. In each case a preliminary hypodermic of morphine (¼ gr.) was given.

The first patient was a woman 32 years of age who was operated upon for varicose veins of both extremities. Gas-oxygen without ether was given for an hour and forty-five minutes. During induction of anesthesia there was moderate cyanosis, but after the first few minutes the patient's color remained pink and conditions were in every way satisfactory, except that there was a tendency to vomit whenever the supply of nitrous oxide was decreased. The operation was completed at 1 P. M. The patient promptly vomited, and nausea and vomiting continued all the rest of the afternoon. She stated that these symptoms were much the same as after ether, but that she preferred the gas-oxygen on account of the quicker disappearance of her mental confusion. (She had been operated upon for hernia eight days before, under ether.)

The second patient was a woman of 46 years who underwent a radical operation for carcinoma of the breast. Gas-oxygen anesthesia was attempted and maintained for forty-five minutes, with the aid of 2 ounces of ether. The patient was at all times more or less cyanosed. Breathing was irregular and there was a constant tendency to struggle. At the end of forty-five minutes the nitrous oxide was discontinued and a light anesthesia kept up for three-quarters of an hour longer with 4 ounces of ether.

Gas-oxygen anesthesia as usually conducted may be divided into three classes; first, gas-oxygen anesthesia alone; second, gas-oxygen anesthesia assisted by ether; third, ether anesthesia modified by gas oxygen. The case last described may, on the whole, be justly called an ether anesthesia *complicated* by gas-oxygen. The results, however, were surprisingly satisfactory. The patient was conscious and talking before being removed from the table; according to the nurse there was no subsequent vomiting and the patient herself reported little or no nausea.

Of course these two cases prove nothing. They are merely examples of two contrasting types frequently met with, the one very susceptible to the good and bad effects of an anesthetic, the other resistant to both. However, neither of these cases would have given the casual observer a very favorable impression of nitrous-oxide oxygen anesthesia.

A satisfactory anesthesia with this agent presents much the same features as a correspondingly satisfactory ether anesthesia. The patient's color should be pink or only slightly dusky, the pupils small or medium, the breathing quiet and regular and the patient sufficiently relaxed to allow the surgeon to do his work without too much annoyance from muscular rigidity.

The conditions usually necessary for such an anesthesia are somewhat as follows: (1) A reasonably tractable patient. (2) A reasonably skillful anesthetist. (3) A willingness on the part of the operator to put up with a certain amount of muscular rigidity or to have the anesthesia deepened by adding ether rather than by the more dangerous

Case.	Age.	Sex.	Operation.	Preliminary Medication.	Quantity of Ether Used.	Duration of Anesthesia.	Nausea and Vomiting.
1	32	F.	For varicose veins	Magendie 8 minims	None	1¾ hours	Vomited twice during operation and four or five times afterward. Nauseated for several hours.
2	55	F.	Curetting of os calcis	None	None	7 minutes	Very little vomiting. Slight nausea.
3	20	M.	Resection of rib for empyema	None	None	29 minutes	None.
4	33	F.	Curetting of uterus	None	None	9 minutes	Vomited twice on operating table at close of operation. Little subsequent nausea
5	39	M.	For varicocele	Magendie 7 minims	None	35 minutes	Retching at close of operation and at least once subsequently. Moderate nausea.
6	55	F.	Curetting of os calcis	None	None	6 minutes	Moderate vomiting. Nausea for several hours.
7	58	M.	Prostatectomy	Magendie 8 minims	1 ounce	20 minutes	None.
8	22	F.	Incision of breast abscess	None	None	10 minutes	Vomited on operating table at close of operation. (No further record.)
9	23	F.	Salpingectomy and appendectomy	Magendie 7 minims	5 drams	45 minutes	Vomited on operating table at close of operation. (No further record.)
10	61	M.	Removal of osteoma from knee joint	None	2 drams	25 minutes	Vomiting of mucus at close of operation. No subsequent nausea or vomiting.
11	30	M.	Repair of fistula of urinary bladder	Magendie 7 minims	1½ ounces	30 minutes	Vomited bile at close of operation. (No further record.)
12	18	F.	Plastic operation on hand, skin grafting	Magendie 6 minims	1 ounce	1¼ hours	Vomited mucus at close of operation and once subsequently. Little nausea.
13	49	F.	For prepatellar bursitis	Magendie 6 minims	4 drams	20 minutes	Vomited two or three times after operation Moderate nausea.
14	48	M.	Removal of lipoma of neck	Magendie 8 minims	3 drams	35 minutes	Vomited once or twice. Little nausea.
15	28	F.	For hemorrhoids.	Magendie 8 minims	3 drams	35 minutes	None.
16	20	M.	Reduction of fracture of olecranon	Magendie 7 minims	None	10 minutes	None.
17	20	M.	Amputation of foot	Magendie7 minims	4 drams	30 minutes	Little vomiting. Moderate nausea.
18	69	M.	Suture of ruptured quadriceps femoris	Magendie 7 minims	1 dram	45 minutes	None.
19	22	F.	For femoral hernia	Magendie 6 minims	1½ drams	35 minutes	Vomited twice. Little nausea.
20	21	F.	Puncture of breast with exploring needle	None	20 drops	10 minutes	Vomited bile on withdrawal of anesthetic. (No further record.)
21	30	F.	Curetting of uterus	None	None	10 minutes	No vomiting. Slight nausea.
22	20	F.	For femoral hernia	Magendie 7 minims	1 dram	35 minutes	None.
23	..	F.	For removal of buried suture from abdominal wall	None	None	5 minutes	In the midst of operation vomited a considerable quantity of food taken four hours before. Moderate subsequent nausea.
24	31	F.	Amputation of thigh	Magendie 6 minims	2 drams	25 minutes	None.
25	20	F.	Excision of tuberculous cervical lymph nodes	Magendie 7 minims	None	55 minutes	Vomited once during operation and at least three times after operation. Moderate nausea.

method of crowding the nitrous oxide. (4) A suitable apparatus. (5) A preliminary subcutaneous injection of morphine or some other sedative.

If "straight ether" were given under conditions similar or parallel to the above, would the patient suffer more subsequent discomfort than after gas-oxygen. The list presented is one of unselected cases, taken in the order in which they came to operation.

It would hardly be worth while to make an exhaustive analysis of these cases or fair to draw general conclusions therefrom. It may be noted, however, that of the seven patients who were free from nausea and vomiting, five received from a dram to an ounce of ether, and that of the eighteen patients who vomited or suffered more or less from nausea, nine received no ether at all. The record of nausea and vomiting in twenty-five unselected ether anesthesias, most of them for minor operations, should suffer very little by comparison with that in the list above tabulated. Such a comparison, however, would be misleading if one were to depend on the written record alone, the reason being that it is impossible to express with precision the severity of a patient's vomiting or the degree of his nausea. The perusal of statistics cannot wholly take the place of direct personal observation. Such observation convinces me that, as regards post-anesthetic nausea and vomiting, gas-oxygen has distinct advantages, though, doubtless, these are more or less overrated. A point worthy of notice is that the vomiting which follows gas-oxyen anesthesia is assisted by the patient's voluntary efforts and we do not so often see the cyanosis—often deep and sometimes alarming—which attends the vomiting efforts of the not yet conscious ether patient.

Frequently patients are met with who have undergone both forms of anesthesia and usually they express themselves as better pleased with gas-oxygen, though it must be confessed that they do not seem wildly enthusiastic in their preference. Indeed, one of these patients, himself a physician, told the writer that he was more comfortable after ether for the reason that his vomiting occurred while he was unconscious, whereas, after gas-oxygen he "knew all about it. Since the above cases were tabulated the writer has tested the comparative after-discomforts of gas-oxygen and ether, making use of himself as a subject for experiment. The tests were made a week apart under practically identical conditions. On each occasion a light breakfast had been eaten and the anesthetic was given shortly after midday for twelve minutes by the same professional anesthetist. In both instances recovery from the anesthetic was characterized by absolute freedom from vomiting but by a tendency to nausea. In the case of ether this was so pronounced that it was deemed wise to remain in the recumbent position for an hour after consciousness returned. After gas-oxygen the subject was up and about in a few minutes. In both instances a tendency to nausea and giddiness persisted through the afternoon, but a fairly substantial supper was eaten, enjoyed, and retained.

If a hundred men and a hundred women of the medical profession, preferably surgeons and anesthetists, would repeat these experiments and report results to (for instance) the American Association of Anesthetists, valuable first-hand information would thus be furnished concerning the relative after-effects of these two forms of anesthesia when uncomplicated by operative procedures.

411 Manhattan Avenue

IS AN ANGINA RATHER THAN TONSILLITIS THE PRECURSOR OF ACUTE RHEUMATISM?

By JENNIE G. DRENNAN, M.D., C.M.,
ROSEBANK, STATEN ISLAND, N. Y.

If one may judge from the statements of some of the authoritative writers on general medicine the prevalent belief appears to be that tonsillitis precedes rheumatism. Thus in Allbutt and Rolleston it is said: "Tonsillitis is not an infrequent precursor of or concomitant with an attack." In modern clinical medicine the statement is made that "American and English physicians for a long time had already called attention to the frequent occurrence of acute rheumatism after an attack of tonsillar angina, etc."; Strümpel says: "Not infrequently the organs of the throat, particularly, appear to be the points of entry for the infection (tonsils and pharyngeal tonsils)."

Now is the throat condition, which so often precedes an attack of acute rheumatism, a real tonsillitis or is it not rather an angina or an inflammatory involvement of the tissues surrounding the tonsils due to the infective organism of the following attack of rheumatism; in other words, is the so-called tonsillitis, which precedes the rheumatic attack, really a tonsillar condition, or is it not rather an angina affecting the surrounding tissues and not the tonsils themselves? The following questions have presented themselves to my mind: Does the patient generally suffer so severely during this precursory attack as he does during a real attack of tonsillitis from which he recovers without an accompanying attack of acute rheumatism? Does he not frequently suffer rather much more from the local discomfort than from the systemic symptoms? or as the Englishman would say, "Doctor, I have a shockin' sore throat but I am well in myself," meaning that the constitutional or systemic symptoms do not cause him any discomfort, but that what discomfort he does suffer comes alone from the local condition. He has no malaise, no fever, no headache, no loss of appetite, etc.; but is in all respects fit except that his throat is sore. I have in mind two such cases: one that of a robust young woman in whom there were no serious after-effects, and the other that of an elderly man, hitherto possessing remarkable health and strength for his age, who, however, later on developed an extremely severe attack of acute rheumatism from which he has not yet recovered. In the case of the former aside from the local discomfort she was apparently well. There was an inflamed condition of the throat, which caused her great difficulty in swallowing and the pillars of the fauces were very much inflamed, the tonsils, however, being only very slightly affected, if at all. Her appetite was good and she made no change in her ordinary diet, but it was with great difficulty that she swallowed this food. As she herself said, "I am hungry; I must eat; but I do not know after I have taken the food into my mouth how I am going to swallow it." Finally the local condition becoming so uncomfortable, she applied for relief and the physician consulted made an application of ichthyol, 10 per cent. in boroglyceride, to the inflamed area. This was rather a matter of expediency than of thought in this case, as the ichthyol was at hand; but still it occurred to him that as ichthyol is beneficial in reducing the inflammation of erysipelas and uterine inflammatory conditions, why not in this one? The result was more than

could have been expected; for almost instantly the stiffness and the soreness disappeared and in their place was left a feeling of flabbiness and softness with no pain. The flabbiness was almost disagreeable until the tissues regained their normal tone. From this on there was no return of the condition and no rheumatic sequela.

In the other case the result was not by any means so satisfactory; for the patient, an elderly man, as I have mentioned above, but one exceptionally well preserved, going to business every day from a commuting distance and at intervals taking long business trips, complained of a sore throat. He consulted a physician who treated the case lightly, told the patient to remain at home for a few days, and gave him a gargle. The condition appeared to be somewhat relieved and after a few days the patient returned to his office, but still suffered from some discomfort in his throat, especially on swallowing. He made the remark, "it is not my tonsils; it is my throat." Not being consulted by him, but merely hearing him make this remark in the ordinary course of conversation I, in an offhand way, remarked, "probably you have a rheumatic throat," and thought no more of the matter until the next day, when he came down with a very sereve attack of acute rheumatism from which he has not yet fully recovered, having had several severe relapses.

Now, the question in my mind is, were either of these cases tonsillitis or were they not from the start rather rheumatic infections, attacking the tissues surrounding the tonsils? I cannot but feel that had they from the start been treated as rheumatic infections they would have sooner yielded to treatment, and that, in the latter case the acute attack of articular rheumatism might have been averted. Will it not always be wise for us so to regard all such conditions of the throat and treat them accordingly, no matter how slight they may be. That a tonsillitis may be due to the same organism I do not wish for one moment to deny; but on the other hand I wish to draw attention to the fact, that every sore throat that precedes a rheumatic attack may not necessarily be a tonsillitis, but may be an involvement of the peritonsillar tissues by the organism, which is responsible for the attack.

The localization of the primary attack is accessible; then why not then and there fight the infection when it is in its primary stage? In both of these cases there were no primary systemic symptoms. Just how beneficial ichthyol may be in this class of cases is a matter for further investigation. That it gave relief in this one case I know, but one swallow does not make a summer. However, if it is, as we know, beneficial in erysipelas, why not in a rheumatic condition of the throat which may be near of kin to it in being a streptococcic infection?

In conclusion I would say that I think that it is highly desirable that we shall treat all acute inflammatory conditions of the throat with an eye to their being the initiatory lesion in a case of acute rheumatism. If they are not, no harm will have been done, and if they are much harm may be prevented. I would like to draw special attention to the acute inflammatory conditions of the throat which do not produce constitutional disturbance as the most dangerous. If the patient has a very severe attack of tonsillitis, which confines him to his bed because he is too ill to remain out of it, then he runs a much better chance of not developing rheumatism as a sequela, than the patient who does not feel ill enough to give up, but who is really ill. Unfortunately these cases often from being so slight do not come under the care of a physician until the rheumatic attack has developed.

Summary.—(*a*) An angina and not a tonsillitis may be the precursor of rheumatism. (*b*) All such throat lesions should from the first be carefully treated with an eye to their probable development into acute rheumatism. (*c*) The beneficial effect of ichthyol deserves more consideration.

DIAGNOSIS OF SO-CALLED SCIATICA.

By E. W. BEDFORD, M.D.,

AND

E. O. RAVN, M.D.,

CHICAGO, ILL.

FROM THE NEUROLOGICAL SERVICE (DR. HASSIN) OF COOK COUNTY HOSPITAL, CHICAGO.

THE old teaching that sciatica symptoms are due to a neuralgia of the sciatic nerve has been practically abandoned at present. It has been established of late by Déjerine[1] and his pupils that a great many cases of so-called sciatica are caused by the involvement of the roots that make up the sciatic nerve and thus the teaching of so-called root or radicular sciatica was introduced into neurology. According to Déjerine, radicular sciatica has the ordinary symptoms of plain sciatica, such as the Lasègue sign, Valleix painful points, etc., but the spontaneous pains are worse than in "troncular," or truncal, sciatica and are aggravated by coughing, sneezing, and straining of the abdominal muscles. Occasionally they spread over the crural nerve which is abnormally sensitive to pressure. Muscular atrophy is not rare, affecting either all of the muscles supplied by the sciatic nerve, so-called total radicular sciatica, or limited to some muscles only, partial radicular sciatica. The Achilles reflex is abolished or diminished, the patellar reflex is present. Sensory disturbances usually predominate. The differential diagnosis from truncal sciatica lies in the sensory disturbances since their topography is strictly radicular, *i.e.* is confined to the anatomical distribution of the spinal roots. At the beginning there is hyperesthesia to touch, cold, heat, and pain, later hypoesthesia, and finally anesthesia. Hyperesthesia frequently occupies the external surface of the leg and thigh. Anesthesia may be distributed along the tracts of various lumbar or sacral roots. In the partial or dissociated form the sensory disorders frequently affect or pertain to one root only. In this form there is dissociated atrophic paralysis of the muscles of the anteroexternal region of the leg, while those of the posterior surface of the leg and thigh remain intact. A circumscribed meningitis, Déjerine states, is the most frequent cause of the radiculitis and is usually syphilitic. Déjerine's teaching was confirmed by his pupils and in this country by A. Gordon,[2] who has published several cases illustrating Déjerine's teaching of radicular sciatica.

Some authors, as Bruce,[3] go so far as to place the cause of sciatica in the lesions of the hip-joint only. Bruce interprets the symptoms of sciatica as a referred pain from the diseased hip joint.

Pitfield,[4] in discussing sacroiliac relaxation as a cause of sciatica, quotes a prominent neurologist of the Massachusetts General Hospital whose name he fails to give, who stated that 90 per cent. of sciatica cases are due to sacroiliac relaxations and dislocations. Pitfield, like Goldthwait, emphasizes the close relationship between the sacral plexus and the

sacroiliac synchondrosis. Any disturbance in this relationship is likely to cause symptoms of pain along the sciatic nerve. This sacroiliac etiology of sciatica has been criticized by Lovett.[5]

Whatever the cause of sciatica may be, it is nevertheless frequently located outside the nerve and the roots making up the sciatic nerve. It is obvious that any lesion that may involve the nerve, the roots of the nerve, or the sacral plexus will give symptoms of sciatica. These possible causes have been sought for in the histories of the Cook County Hospital for the past four and one-half years. During this period 400 cases were admitted under the tentative diagnosis of sciatica. All of these patients presented symptoms of sciatica as their chief complaint. It was found that approximately one-half showed definite and various conditions that were not sciatica at all, but in which sciatica was merely a symptom. Of these 400 cases admitted as sciatica during 1916, in 75 per cent. the diagnosis of sciatica was finally modified, while in 1915 it was rejected in 56 per cent., in 1914 in 40 per cent., in 1913 and 1912 also in 40 per cent. In other words, the character of sciatica diagnosis was greatly improved in the past two years, which can be explained by the fact that in the past two years much more attention has been paid to the underlying factors causing sciatica. At present roentgenograms are made in every case and orthopedic considerations are studied more thoroughly. It was found that not only one or two but numerous and variable clinical entities presented sciatic pain as their chief symptom. Of those remaining cases in which an exhaustive study did not reveal anything definite, the diagnosis of sciatica or neuritis was made reluctantly. Many of these cases would probably be classified under sacroiliac disturbances, defective "static balance," etc., by the authorities advocating these respective theories. Since a classification of this nature is still arbitrary, these cases, in which examinations were negative, will not be discussed to any great extent except to state that 79 per cent. were in men and the average age was 39 years. The right side was affected in 42 per cent. of these cases, the left side in 41 per cent., and both sides in 17 per cent. Since 79 per cent. occurred in men, most of whom were doing heavy manual work, it appears plausible that their pains in the lower extremities may have been manifestations of some over-exertion.

Of the other 50 per cent in which a correct diagnosis could be established, 8 cases proved to be purely functional (hysteria and neurasthenia). The rest were organic. In ten cases a diagnosis of lumbago or muscular rheumatism was made. Among other cases to be enumerated below there were three of chronic nephritis and one of pyelonephritis. This etiology, however, is rare, though pointed out in the literature by Lapinsky.[6]

An anatomical classification of other but more frequent causes of sciatica in our series of cases will now be presented.

Cerebrospinal cord lesions have been mistaken for sciatica 13 times; tabes dorsalis, 7 cases; acute pneumococcus meningitis, 2 cases; cerebrospinal lues, 1 case; chronic anterior poliomyelitis, 1 case. In other words, instead of various cerebrospinal cord lesions, a diagnosis of sciatica was made. To illustrate at least one instance we will cite the following case:

C. S., American housewife, age 52, with good habits, entered the service of Dr. Hassin, complaining of an acute pain of four months' duration in the back and down the right thigh and leg, shooting in character, worse on standing and walking. There was a sense of constriction about the waist and urination was frequent. Past history: Rheumatism in right wrist eleven years ago, pneumonia several times, typhoid fever fifteen years ago; denies venereal diseases; has had no miscarriages; one son is living and well; her husband is living and well; menstruation is regular. Mother, aunt, and sister had pulmonary tuberculosis. Physical examination revealed a well-developed woman with normal mentality but with Argyll-Robertson pupils and normal fundi. Positive Kernig and Lasègue signs on the right side; Achilles absent on the right side but present on the left; knee jerks and sensibility were normal; Rhomberg, ataxia, and atrophies were absent. Wassermann on spinal fluid was strongly positive on two occasions. Cell count of 5 lymphocytes per cubic millimeter. Nonne and Noguchi tests were positive. X-ray examinations were negative. The patient improved markedly under treatment with mercury and arsenobenzol. This pâtient did not have sciatica, but tabes, which was shown by the Argyll-Robertson pupils, urinary disturbances, lost Achilles reflex, and spinal fluid findings, and was also confirmed by the results of the antiluetic treatment.

Diseases of the spinal column: Tuberculosis of the spinal column was overlooked in two instances; spondilitis deformans in 11 cases; old fracture of the spine in 1 case; scoliosis in 2 cases, and kyphosis in 1 case. Mild or incipient cases of spondylitis deformans are more numerous than the other members of this group because it is only with the aid of a Roentgenographic examination that a positive diagnosis can be made in some cases. To illustrate:

P. T., single, Italian laborer, 34 years old. Complained of pain in the back and left leg of two years' duration. The present attack began two months ago. The pain is worse on walking. Past history is negative. Physical examination revealed moderate tenderness over the lumbar spines, but the spinal column itself was not very rigid. There was tenderness along the left sciatic nerve. The Lasègue sign was positive on the left side. Reflexes and sensibility were normal. There was no pain on abduction or outward rotation of the thighs. Examination otherwise was negative. The x-ray report by Dr. E. Blaine says: "Left transverse process of fifth lumbar vertebræ is large and of butterfly outline, which articulates with the upper portion of the sacrum and ileum—a case of sacrolization. Shadows indicating spondylitis deformans are also present." The patient left the hospital before any surgical treatment could be carried out, but the case resembles similar conditions described recently by Shackleton[7] and Fassett[8], who have reported the results after excision of these transverse processes.

Conditions of the sacroiliac joint: Tuberculosis of the sacroiliac synchondrosis was discovered in 5 cases, sacroiliac arthritis in 2 cases, sacroiliac strain in 5 cases. Dystocia caused symptoms of sciatica in three instances. A history of trauma or strain was secured in 24 cases in which sciatica pain appeared after heavy lifting, contusions to pelvis or hip, etc.

A. K., American housewife, 28 years old, stated that for the past twelve years, while washing clothes, etc., she had a sharp pain in left hip and difficulty in straightening up. Four months ago, after dancing one evening, the pain became worse. At the time of entrance pain was present mostly on walking and on rotating the body. The obstetrical history showed that her first labor was instrumental; her back was weak after the second labor, which was normal; the history was otherwise negative. Physical examination: The patient was very obese; head, chest, and abdomen normal. Kernig and Lasègue signs were positive on both sides. Any sudden movement of either thigh caused pain in the left hip region, but no pain on abducting the thighs. On compressing the iliac bones or on direct pressure there was pain over the left sacroiliac joint. Pain was present over this region when the patient raised the right leg while standing on the left leg. Reflexes, sensibility tests, and Roentgen examinations were negative. A diagnosis of sacroiliac strain was made. After fixation of pelvis and rest in bed patient improved greatly.

Pelvic lesions comprise the most striking causes of sciatica symptoms of which we can cite the following conditions: blastomycosis combined with pelvic abscess, 1 case; retroperitoneal sarcoma, 1 case; carcinoma of pelvic bones secondary to cancer of breast, 2 cases; carcinoma of uterus and pelvis, 1 case; thrombophlebitis of common iliac vein, 1 case; retroperitoneal abscess, 1 case; ischiorectal abscess, 2 cases; fibroid of uterus, 2 cases; retroversion, 1 case; gonorrheal prostatitis, 1 case. Of these cases which were all admitted as sciatica, the most remarkable and unusual are the cases of blastomycosis and retroperitoneal sarcoma.

P. K., a German laborer, age 32, complained of constant dull, aching pain in right leg of about three weeks' duration, beginning in the right hip and gradually extending down the leg, hoarseness and sensation of dryness in the throat, occasional cough, loss of strength and weight, night sweats, nocturnal urination, and dysuria. His appetite was good and the bowels were regular. Patient came to Chicago eight months ago, previous to which time he had been a farm laborer. The present illness was first noticed three months before entrance. Family and venereal histories were negative. He used tobacco and alcohol moderately. Physical examination revealed evidences of a pulmonary tuberculosis, although tubercle bacilli were not found in the sputum. An ulcer the size of a silver quarter was present on the right forearm and had been there for one year. Temperature fluctuated from normal to 101°; pulse 94 to 130, and was weak; respiration 20 to 32. The patient died after the lapse of a short time in the hospital. Necropsy by Dr. H. G. Wells demonstrated a pulmonary and laryngeal tuberculosis, associated with a systemic oidiomycosis involving especially the lungs, prostrate, and sacroiliac synchondrosis. "In the retroperitoneal tissue of the pelvis there was a fluctuating mass filled with purulent material extending from the promontory of the sacrum down through the right obturator foramen, the anterior surface of the sacrum was eroded, and the periosteum was necrotic. A pocket of soft eroded bone replaced the right sacroiliac joint. The nerve trunks of the plexus were eroded. The process continued through the obturator foramen and about 6 to 8 cm. distally into the thigh, extending upward to the upper margin of the iliac bone. The left sacroiliac articulation was not involved. Microscopic study of the tissues proved that the case, which clinically and at the autopsy appeared to be tuberculosis, was one of generalized oidiomycosis associated with pulmonary and laryngeal tuberculosis."

A complete report of the case was presented to the Chicago Pathological Society by Dr. H. G. Wells. The sciatica symptoms in this case were evidently due to the involvement of the sacral plexus.

J. D., Swiss teamster, 43 years of age, married, complained of a constant aching pain in the left calf of six months' duration; the pain has gradually extended to the left hip in past two months; it keeps the patient awake at night, but is not aggravated by walking. Appetite is good and the bowels are regular. The history is otherwise negative. Upon physical examination a large, firm mass was found on left side of prostate adjacent to rectum. This mass was not tender and was not evident on abdominal palpation. There was marked atrophy of left thigh, which was 10 cm. smaller in circumference than right thigh. Pain in left hip joint on manipulation. Tenderness of calf muscles. Steppage gait with left foot. Reflexes and sensation, urine, and blood examinations were negative. Wassermann was positive on spinal fluid, but the latter was otherwise negative. Roentgen examinations showed bony changes in the left ischium. A diagnosis of retroperitoneal sarcoma was made and confirmed by operation which was done later on to relieve urinary retention and intestinal obstruction which developed subsequently. The sarcoma was found in the left side of the true pelvis pressing upon the rectum and urinary bladder. In this case a "sciatica" was a symptom of a retroperitoneal sarcoma.

Hip-joint lesions may be the cause of sciatica though they are not as frequent in this classification as Bruce[3] intimates. The following pathological conditions of the hip-joint have been registered in the hospital records: Tuberculosis of the hip-joint, 8 cases; chronic arthritis of the hip-joint, 6 cases; arthritis deformans, 6 cases; acute articular rheumatism, 3 cases; subacute articular rheumatism, 3 cases; chronic articular rheumatism, 3 cases; luetic arthritis of hip, 1 case; gonorrheal arthritis of the hip, 2 cases; contusion of the hip, 1 case; relaxation of the ligaments of the hip after an old dislocation, 1 case; old fracture of the neck of the femur, 2 cases.

Diverse conditions affecting the lower extremities and causing sciatica manifestations have been classified in the last group. The records reveal: Intermittent claudication, 1 case; erythromelalgia, 1 case; metastatic carcinoma of the upper femur secondary to breast cancer, 1 case; thrombosis of the femoral vein after typhoid fever, 1 case; acute periostitis of the femur, 1 case; endothelioma of the sciatic nerve, 1 case; bullet wound of the sciatic nerve, 1 case; varicose veins, 3 cases; pes planus, 4 cases.

There were also numerous cases of polyneuritis which were diagnosed primarily as sciatica. Of these, 16 were of alcoholic origin, 1 of diabetic, and 1 of typhoid. One case of traumatic neuritis was recorded. In reference to this group it may be proper to point out that Quénu[9] has stated that sciatica may be due to pressure of varicose veins upon the sciatic nerve in the neighborhood of the sacrosciatic foramen.

From the classification of the groups mentioned above one can see how numerous the causes of so-called sciatica may be and how imperative it is in any case of sciatica to attempt to locate the source of these pains. This is not only absolutely necessary for the sake of a mere diagnosis but, what is more important, for the purpose of making a correct prognosis and of instituting proper treatment. Undoubtedly there are many more etiological factors instrumental in causing what is commonly diagnosed as sciatica, but we have attempted to point out merely those conditions which have occurred in the various services of the Cook County Hospital in the past four and one-half years.

Treatment of Severe Hyperemesis Gravidarum.—Weigh the patient, put her to bed, test urine for acetone, take blood pressure. If she loses flesh, has acetonuria, low blood pressure, or fever proceed at once to abortion. If she is normal, give liquid nourishment in small quantities and often, ice-cold if necessary. Give stomach lavage for the mental effect.—Jung in *Deutsche medizinische Wochenschrift.*

Death Rate in Mexico City.—According to the official bulletin this rate for last March was about 40 per 1,000 inhabitants. The natives suffer at the same period from respiratory and enteric conditions. Typhus is prevalent and violent deaths numerous.—*Boletin del Consejo Superior de Salubridal.*

MEDICAL RECORD.

THE RELATIONSHIP OF THE DUCTLESS GLANDS TO DISTURBANCES OF THE OPTIC NERVE.

OF the ductless glands it is the hypophysis, or pituitary body, which plays a considerable and significant rôle in the genesis of disorders of function of the optic nerve. For this reason a brief review of the optic nerve findings in disease (hypertrophy or tumor formation) of the hypophyseal body is very instructive. The mechanical effect of enlarged hypophysis may result in the production of heteronymous hemianopsia and the hemianopic pupillary syndrome. Complete temporal hemianopsia suggests disease of the hypophysis. But real diagnostic value should also be given to such findings as heteronymous defects of a quadrant or octant or even of the color sense alone, as well as to heteronymous scotomata.

As Schirmer (*Journal of Nervous and Mental Diseases*, October, 1916) mentions, injury to the nerve fibers paralyzes the peripheral fibers first, because they have the poorest function. It is very important to know that the color sense may be disturbed or even lost in many cases before white perception has shown any abnormalities. As a consequence there may be concentric contraction of the visual fields for color without the fields for white perception showing any change from the normal outlines. So great is the power of the nerve fibers to resist destruction and to recover when the pressure is relieved before actual destruction has taken place, that in choked disc, in case decompression has been performed, it is not surprising to find that there is a period of amblyopia for a week or two or more, soon to be followed by useful vision. In these cases, furthermore, it has been discovered that if the hemianopsia is complete or almost complete the hemianopic pupillary reaction is generally found present.

Pressure atrophy of the optic nerve may exist, to be sure, without evidence of hypersecretion or hyposecretion, as frequently occurs in such conditions as pregnancy, extirpation of the thyroid, infectious diseases, and atrophy of the gonadal system. Schirmer observes that the optic nerves may be affected by the direct chemical action of excessive ductless gland secretion, as in excessive secretion of the thyroid in cases of Graves' disease and possibly in some cases of pituitary hypersecretion. In some cases inflammation, in other instances atrophy may result.

Again we must state that in hypophyseal pressure upon the optic chiasm the color fields may be distorted or lost before similar changes have taken place in the white fields, and hence bitemporal hemichromatopsia may occur early in pituitary disease (as in acromegaly). The lesson to be learned from this point is that one should avoid the error of pronouncing the fields of vision normal because the white fields are normal, for, if the color fields be tested first, the abnormality in this connection may be noted and early pressure upon the fibers of the optic nerve thus diagnosed. In all of our examinations of the disc and the surrounding structures we should hold well in mind the fact that from the examination of the eye alone we cannot and need not make a diagnosis of the etiological basis of the condition found in the optic disc. Here the laboratory worker, the neurologist, and the ophthalmologist should co-operate whole-heartedly and for the best interests of the patient.

THE TREATMENT OF GONORRHEA BY ELECTROLYSIS.

SOMETHING over two years ago we called attention to the use of electricity in the abortive treatment of acute gonorrhea, our remarks at that time being based upon an article by G. Li Virghi of Naples, who reported that for about two years he had used the method which he described in his paper and that during that time he had treated 92 cases with 100 per cent. of cures. Some of Li Virghi's results seemed truly remarkable, rapidity of cure being an outstanding feature in most cases; and in our concluding paragraph we said that if his claims were verified by other observers a great step forward would have been made in the treatment of this treacherous disease.

The verification which we considered to be necessary now seems to have been furnished, for Charles Russ of London (*The Practitioner*, September, 1916) reports his results in the treatment by electrolysis of 100 cases of gonorrhea, 69 of which were of the acute and 31 of the chronic variety. His confirmation of the value of electrolysis in the treatment of acute gonorrhea is all the more convincing since it seems certain that these two observers, one in Naples and the other in London, conceived the idea of employing electrotherapeutic measures in the treatment of acute gonorrhea entirely independently of each other. Li Virghi's article was published in Paris, April 15, 1914, but Russ appears to have priority of publication, for he published an article in the *Lancet* of February 14, 1914, referring to his research work from 1909 to 1914 on electrolysis as a means of destroying bacteria and also detailing the results of his treatment by electrolysis of various types of clinical cases, among which were two cases of gonorrhea. In the *British Medical Journal*, June 12, 1915, Russ reported having treated 28 cases of gonorrhea by his method; while in a book entitled, "A New Treatment for Gonorrhea" (Lewis & Co., London, 1916) he gives

his method in detail and refers to the treatment of 70 cases. With the completion of a series of 100 cases Russ feels that he should again bring the subject to the attention of the profession, for on the basis of his experience he considers that his method marks a distinct advance in the treatment of this disease. Further confirmation of the value of electrolysis in the treatment of gonorrhea is furnished by Major E. G. Ffrench in the course of an article entitled "The Treatment of Venereal Disease in the Army" (*The Practitioner*, May, 1916). He states that some ten cases of gonorrhea have been treated by Russ' method at the Military Hospital, Rochester Row, S. W., London, and that the treatment seems worthy of every investigation and will be very thoroughly tested.

In Russ' series of 69 acute cases the average number of treatments required was 16, with a minimum of 5 and a maximum of 34; with 31 chronic cases the average number of treatments was 20, minimum 14, and maximum 35. In Li Virghi's series of 92 cases there were no complications which he thought should be attributed to the method, though there were some which he considered due to forcible injections made by the patients before consulting him. In Russ' series of 100 cases, acute and chronic, complications occurred in six patients as follows: epididymitis, 4; ophthalmia, 1; arthritis, 1. In the latter case the patient's doctor had incised a periurethral abscess the day before sending him for treatment by electrolysis; hence it is a question as to which is responsible for the metastatic infection. No cases of stricture have been known to follow electrolysis in this series.

For details as to the methods of procedure the reader is referred to the various articles by Li Virghi and Russ that have already been quoted. Suffice it to say that there is nothing at all complicated about the treatment, and as the results were so remarkably good it would seem that the time has come when electrolytic treatment should be thoroughly tested in the clinics of some of our own genitourinary specialists.

TYPHUS FEVER.

Typhus fever, one of the oldest diseases of which record can be found, was up to two years ago an almost forgotten malady, at any rate, as an epidemic. True, in many countries, in which sanitation was backward, and especially where domestic hygiene was lacking, typhus was endemic, and, as First Lieut. Horace C. Hall points out in the *Military Surgeon*, November, 1916, in the Balkans, Turkey, Persia, Arabia, China, and in Asia generally typhus has been endemic since the earliest of folk-lore legends. And within the past three centuries, along lines of commercial intercourse and travel, the disease has become largely endemic in Russia, Poland, Austria, Germany, and Latin America. But, as said before, there has been no serious epidemic of typhus fever until war conditions spread the disease through Serbia, and disturbed economic conditions in Mexico disseminated the infection far and wide in that country. It is a disease which is spread by neglect of proper sanitary precautions and conditions favorable to vermin also favor the spread of typhus. In fact, it has been demonstrated that the disease may be transmitted from man to monkey and therefore presumably from man to man by means of the common body louse. While admitting that the body louse does convey the infection and that the head louse and bedbug may be regarded as suspicious conveyers, Hall thinks that it has not been conclusively proven that vermin are the only means of conveying the disease. The predisposing causes of typhus are famine, filth, overcrowding, and conditions favorable for the thriving of vermin.

The main means of prevention are to find and kill the lice and bugs, a difficult task indeed when dealing with a primitive and dirty people such as the Mexican peons, the class of individuals among whom Hall gained his experience.

With regard to treatment it was found that immunizing vaccine, so far available, had not been of any material service. Hall controls the fever with baths, the delirium with bromides and an ice-cap, and gives egg albumin in water, even though it has to be placed in the stomach through a tube passed through the nose. He gives large broken doses of calomel, followed by magnesium sulphate and high enemata which are left in as long as possible. If the urine is scanty, these enemata are of physiological salt solution. He begins the strychnine as a matter of routine, to combat the muscular weakness which is certain to follow. An ice-cap is kept on the patient's head and he is bathed not oftener than four times within the twenty-four hours. When the crisis is approaching Hall gives hypodermic injections of camphor in oil, alternated with spartein sulphate, to tide over the period.

The only specific complication noticed by this observer is that of gangrene of the leg, most commonly the left, below the seat of election for amputation just below the knee. It is a dry gangrene, extremely painful, and slow to show the line of demarcation. In 95 per cent. of such cases it is best to amputate, as soon as the line of demarcation is indicated. Hall remarks that in 25 per cent of the educated, high-strung civilized American patients he has treated for this disease he has observed a form of toxic insanity complicating the final outcome of the cases. This is due, no doubt, to the continued high fever and severe toxic poisoning. This insanity is not transitory, that is to say, that while within a few weeks the reasoning power returns to nearly normal, there remains a mild delusional insanity for a considerable period.

Sublingual Medication.

One method of administering medicines has, rightly or wrongly, received very little attention from the medical profession. This is the practice of placing a dry tablet containing the drug beneath the tongue in the sublingual space and having the patient hold it there without swallowing until the taste disappears. This method is strongly recommended by Paulson (*Practitioner*, 1916, XCVII, 389) and is enthusiastically endorsed by Cooper (*Ibid*, page 493). These writers are apparently of the opinion that absorption from the sublingual space takes

place more quickly than from any other portion of the body, though probably they would admit that medication injected intravenously would exert its action more rapidly. It is difficult to get information on this question. Most of the standard works on physiology either fail to mention the mouth as a place where absorption may occur or else say that its structure is unsuited for absorption. Indeed, when one considers that the submaxillary and sublingual glands both empty their secretions into the sublingual space it is difficuult to see how absorption in this area could be very rapid or complete. It should not be a very difficult matter to investigate this question experimentally both in man and in animals. Only in this way can we obtain exact information. The method offers so many advantages that it would be well worth investigation. The authors claim that it surpasses hypodermic injection in rapidity and effectiveness and it certainly does excel in ease and simplicity. The doing away with the necessity for the sterilization of a hypodermic syringe would be a great help to all of us and we hope that the method will be thoroughly tried out and its usefulness or worthlessness fully demonstrated.

A New Sign of Sciatica.

None of the evidences of sciatica, such as pain over the nerve, Lasègue's sign, muscular atrophy, modifications of electrical reactions, scoliosis, elevation of the heel in walking, fibrillary contractions of the leg muscles, clonus of the glutei, abolition of the Achilles reflex, lessening of the gluteal fold, etc., is in itself pathognomonic of the disease in question, and in a given case some of them will be absent all the time. Hence, a true pathognomonic sign would prove of great value in cases where rapid and certain diagnosis is necessary. Pisani believes that he has discovered such a sign in connection with the behavior of the abdominal reflex on the affected side (*Malpighi*, July 1-15). He has found this to be the predominating symptom in every case thus far examined. It consists in the fact that the reflexes are less pronounced or absent on the sound side. The superior, median, and inferior reflexes should all be tested. The patient lies on his back with his abdominal walls fully relaxed, and the limbs extended symmetrically. The predominance of the reflex on the affected side is not in itself strictly pathognomonic, but is found in over 80 per cent. of all patients examined; while the presence of this phenomenon in non-sciatic cases means some condition which could never be confounded with sciatica, so that the sign has all the force of actual pathognomonic symptoms. As already stated no negative results have yet appeared.

Cerebrospinal Meningitis in Geneva.

Historians teach us that epidemic cerebrospinal meningitis is first known to have occurred in the spring of 1805, when it prevailed to a notable extent in Geneva. In the following year, Vieusseux, a Genoese physician, wrote the first account of the new malady. The number of fatalities inside the city walls was 33. The first cases occurred outside the walls, in one of the forlorn suburbs. According to Mallet there has never been another epidemic of the disease in Geneva up to the present time (*Revue médicale de la Suisse Romande*, July 20.) Sporadic cases occur, but have never shown cumulation, nor could any case be imputed to contagion. The vital statistics go back to 1871, and from that year to 1900 but nine cases were reported, all fatal. From 1900 to 1910 there were 25 cases, the increase having been associated partly with the diagnostic enrichment of lumbar puncture. From 1910 to 1916 the number of cases was 21, and 6 of these occurred last June, while the total for 1915 was 9. In other words, there has been an incidence of 15 cases in the past 18 months. To offset these figures there were no cases in 1911 and 1913. A further analysis showed the existence of maxima in 1904, 1908 and 1914-15, periods which correspond to the great military mobilizations. The great fatality of the disease has abated since 1910, when serotherapy was introduced. Evidence has accumulated that the disease is spread by carriers. It seems extraordinary at first sight that a disease which first appeared in epidemic incidence in a close community, and which has appeared sporadically in the latter for at least 45 years, has never since exhibited epidemicity. The increased incidence of the past 18 months may indicate the approach of an epidemic, but Mallet thinks it more likely that it will be succeeded by a sudden decline.

News of the Week.

The New York Diagnostic Society, having for its object the establishment of institutes for group diagnosis, was recently organized in New York, partly, at least, as the result of a suggestion made by Dr. Charles H. Mayo of Rochester, Minn. Speaking before the Catholic Hospital Society at Milwaukee a short time ago Dr. Mayo expressed the opinion that the one great present day need in hospital advancement was a hospital devoted entirely to diagnosis. The officers of the society are: *President*, Dr. M. Joseph Mandelbaum; *Viee-Presidents*, Dr. De Witt Stetten and Dr. Otto Hensel; *Treasurer*, Dr. Julius Auerbach; *Secretary*, Dr. Monroe Aünstler.

Pasteur Exhibit.—In connection with the meeting of the American Association for the Advancement of Science in New York during Christmas week preparations are being made for an exhibition of objects relating to the work of Louis Pasteur. Letters, manuscripts, pictures, microscopic preparations, and other material are desired by the committee in charge, and it is requested that any one willing to loan such exhibits communicate with Prof. C.-E. A. Winslow, American Museum of National History, Seventy-seventh Street and Central Park West, chairman of the subcommittee, or with Prof. J. G. Hopkins, College of Physicians and Surgeons, 437 West Fifty-ninth Street, New York.

War on Heart Disease.—Following the organization of the Association for the Prevention and Relief of Heart Disease, the New York Post-Graduate Hospital recently announced the formation of a special committee to aid the work of its cardiac department. The committee will assist the visiting nurses and the social service workers, who now visit the heart patients in their homes, see that they are properly cared for and aid them when necessary in finding work suitable to their physical condition.

New Home for Nurses.—Plans have been filed with the New York Building Department for the erection of a seven-story fireproof home for nurses of the New York Eye, Ear, and Throat Hospital. The home will be located in the rear of the hospital building, with a frontage of 125 feet on the north

side of Sixty-third Street. It is estimated that the cost will be $275,000.

Street Accidents.—During the month of November, 1916, there occurred 65 deaths in traffic accidents in New York City, an increase of 19 over the number for November, 1915. Of these, 42 fatalities were due to automobile accidents, as compared with 18 a year ago. Of those killed, 32 were children. In the State outside of New York City, during the month 37 persons were killed by automobiles, 4 by trolleys, and 4 by wagons, a total increase of 14 over the figures for last year. In New Jersey, the figures for the month were 20 persons killed by automobiles and 4 by trolleys and wagons. The Safety First campaign needs reviving.

Personals.—Dr. Abraham Jablons of New York has been commissioned lieutenant-surgeon of the White Cross Hospital and Relief Association.

Dr. M. Joseph Mandelbaum was the guest of honor at a dinner given by the New York Diagnostic Society in the Astor Gallery of the Waldorf-Astoria on Tuesday evening, December 5.

Presentation of Dr. Raymond's Portrait.—On Monday, December 4, the graduating class of the Long Island College Hospital presented to the college a photographic portrait of the late Dr. Joseph H. Raymond, formerly secretary of the Faculty and professor of hygiene. Dr. John D. Rushmore made the address of acceptance.

Southern Medical Association.—At the annual meeting of the association held in Atlanta, Ga., on November 16 and 17, Dr. Duncan Eve, Nashville, Tenn., was elected *President*, and Dr. Stewart R. Roberts, Atlanta, Ga. and Dr. Bransford Lewis, St. Louis, Mo., first and second *Vice-Presidents* respectively. Dr. Searle Harris, Birmingham, Ala., was re-elected *Secretary-Treasurer*, and editor of the *Southern Medical Journal*. Memphis was selected as the next place of meeting. Announcement was made at the closing session that the sum of $10,000 had been subscribed to pay off the indebtedness on the *Journal*.

Penobscot County (Me.) Medical Association.—The sixty-second annual meeting of this society was held at Bangor on November 16, when the following officers were elected: *President*, Dr. William P. McNally, Bangor; *Vice-President*, Dr. J. B. Thompson, Bangor; *Secretary-Treasurer*, Dr. Harris J. Milliken, Bangor.

Obituary Notes.—Dr. CHARLES LOUIS BEIL of New York, a graduate of Bellevue Hospital Medical College, New York, in 1898, and a member of the Medical Society of the State of New York and the New York County Medical Society, died on November 30, aged 40 years.

Dr. HENRY JONATHAN DEARBORN of Mount Sterling, Ill., a graduate of Rush Medical College, Chicago, in 1888, died at his home on October 29, from cerebral hemorrhage, aged 51 years.

Dr. FRANK KERRICK GREEN of Louisville, Ky., a graduate of the Medical Department of the University of Louisville, in 1899, died at Perryville, Ky., on October 26, aged 46 years.

Dr. ROMEO O. KEISER of Columbus, Ohio, a graduate of Ohio Medical University, Columbus, in 1898, and of the Cleveland-Pulte Medical College in 1899, died at his home on November 1, aged 46 years.

Dr. JOHN T. DUNN of Pasadena, Cal., a graduate of the Medical School of the University of Minnesota, Minneapolis, in 1904, died on October 26, aged 37 years.

Dr. JOHN EDWIN WALKER of Thomaston, Me., a graduate of the Medical School of Maine, Portland, in 1884, and a member of the Maine Medical Association and the Knox County Medical Society, died on November 22, aged 58 years. Dr. Walker was State prison physician of Maine for twenty-six years.

Dr. WILLIAM FINDER, JR., of Ballston Spa., N. Y., a graduate of Long Island College Hospital, Brooklyn, in 1882, and of Columbia University College of Physicians and Surgeons, New York, in 1883, died at his home on November 20, aged 61 years.

Dr. HENRY SELDEN NORRIS of New York, a graduate of New York University Medical College in 1876, and a member of the American Medical Association, the Medical Society of the State of New York and the New York County Medical Society, and consulting specialist at Bellevue Hospital, died at his home on November 19, aged 69 years.

Dr. ABNER HAYWARD of Mount Clemens, Mich., a graduate of Cleveland University of Medicine and Surgery in 1866, died at his home on October 28, from cerebral hemorrhage, aged 86 years.

Dr. DAVID JOHNSON CULVER of Harrisville, N. Y., a graduate of the University of Vermont, College of Medicine, Burlington, in 1881, and a member of the American Medical Association, the Medical Society of the State of New York, and the Lewis County Medical Society, died at his home on October 29, from arteriosclerosis, aged 60 years.

Dr. WILLIAM MCMANN of Gardner, Ill., a member of the Illinois State Medical Society and the Grundy County Medical Society, died at his home on October 24, aged 78 years.

Dr. CECIL C. KIMMEL of Fort Wayne, Ind., a graduate of the Indiana Medical College, School of Medicine, of Purdue University, Indianapolis, in 1907, and a member of the American Medical Association, the Indiana State Medical Association and the Allen County Medical Society, died at the Lutheran Hospital, Fort Wayne, on October 18, from pneumonia, aged 34 years.

Dr. JOHN B. ARMSTRONG of Chicago, Ill., a graduate of the New Orleans School of Medicine in 1869, died at his home on November 8, from heart disease, aged 69 years.

Dr. JONATHAN HENRY WOODS of Brookline, Mass., a graduate of the Long Island College Hospital, Brooklyn, in 1880, and of Columbia University, College of Physicians and Surgeons, New York, in 1881, and a member of the American Medical Association, the Massachusetts Medical Society, and the Norfolk District Medical Society, died at his home on November 16, after a short illness, aged 66 years.

Dr. HARRY W. WEYANT of Philadelphia, a graduate of the University of Pennsylvania, School of Medicine, Philadelphia, in 1895, and a member of the Medical Society of the State of Pennsylvania and the Philadelphia County Medical Society, died at his home on November 2, from pneumonia, aged 47 years.

Dr. HIRAM M. WINN of Sterling, Okla., a graduate of the College of Physicians and Surgeons, Keokuk, in 1892, died at his home on October 16, aged 64 years.

Dr. WILLIAM G. DUBOIS of Camden, N. J., a graduate of the Hahnemann Medical College and Hospital of Philadelphia in 1880, died at his home on October 28, aged 59 years.

Dr. ALBERT PHILIP OHLMACHER of Detroit, Mich., a graduate of the Northwestern University Medical School, Chicago, in 180, and a member of American Medical Association, the Michigan State

Medical Society, and the Wayne County Medical Society, died at his home on November 10, aged 51 years.

Dr. Joseph Hammond Huston of Clintondale, Pa., a graduate of Jefferson Medical College of Philadelphia in 1866, and a member of the Medical Society of the State of Pennsylvania and the Clinton County Medical Society, died in the Lock Haven Hospital on October 26, from disease of the bladder, aged 78 years.

Dr. John W. Webster of Siloam Springs, Ark., a graduate of Missouri Medical College, St. Louis, in 1884, and a member of the Arkansas Medical Society and the Benton County Society, died at his home on October 21, aged 69 years.

Dr. Elmer G. Myers of Canton, Ohio, a graduate of Starling Medical College, Columbus, in 1889, died at his home on November 4, from rheumatic endocarditis, aged 53 years.

Dr. Edwin A. Lex of Irvington, Ky., a graduate of the Medical Department of Kentucky University, Louisville, in 1903, died in St. Joseph's Infirmary, Louisville, on October 26, from typhoid fever, aged 40 years.

Dr. Peter J. McCahey of Philadelphia, a graduate of Jefferson Medical College of Philadelphia in 1885, died at his home on October 22, from heart disease, aged 60 years.

Dr. Fenton D. Drewry of Virgilina, Va., a graduate of the Medical College of Virginia, Richmond, in 1898, and a member of the Medical Society of Virginia and the Halifax County Medical Society, died at the Sara Leigh Hospital, Norfolk, following an operation for appendicitis, on October 18, aged 39 years.

Dr. Asa M. Stackhouse of Moorestown, N. J., a graduate of the Hahnemann Medical College and Hospital of Philadelphia in 1868, died at his home on October 6, aged 72 years.

Dr. Richard Frederick Winsor of Omaha, Neb., a graduate of the University of Illinois, college of Medicine, Chicago, in 1906, and a member of the Illinois State Medical Society, the Nebraska State Medical Association, the Douglas County Medical Society, and the American Medical Association, died at his home on October 21, from pneumonia, aged 36 years.

Dr. Gilman Corson Dolley of Manila, P. I., a graduate of the Medico-Chirurgical College of Philadelphia in 1907, a member of the United States Army and resident physician at the United States Leprosarium Culion, Palawan, died in Manila on October 21, from pneumonia, aged 37 years.

Dr. Andrew L. Marugg of Spechts Ferry, Iowa, a graduate of the Northwestern University Medical School, Chicago, in 1898, died in the Mercy Hospital, Dubuque, Iowa, on October 31 from pneumonia, aged 42 years.

Dr. Oliver C. Ormsby of Rexburg, Idaho, a graduate of Rush Medical College, Chicago, in 1870, died at his home on October 26, from cerebral hemorrhage, aged 73 years.

Dr. Marvin Fisher Smith of Hampton, N. H., a graduate of Dartmouth Medical School, Hanover, N. H., in 1883, died at his home on October 31, aged 64 years.

Dr. Wade H. Chase of Rutland, Ohio, a graduate of the Starling Medical College Columbus, Ohio, in 1897, died at his home on October 8, from carcinoma, aged 56 years.

Dr. Louis Edward Gott of Falls Church, Va., a graduate of the University of Maryland, School of Medicine, Baltimore, in 1861, and a member of the Medical Society of Virginia and the Fairfax County Medical Society died in the Georgetown University Hospital, Washington, on October 29, from prostatic disease, aged 76 years.

Dr. Lewis A. Burck of Frederick, Md., a graduate of Atlantic Medical College Baltimore, in 1895, and a member of the Medical and Chirurgical Faculty of Maryland and the Frederick County Medical Society, died in the City Hospital of Frederick on October 16, from cerebral hemorrhage.

Dr. John F. Maddox of Orlando, Fla., a graduate of the Eclectic Medical College, Cincinnati, in 1877, died in Edinburg Ind., on October 18, from cerebral hemorrhage, aged 71 years.

Dr. Henry D. Long of New York, a graduate of Johns Hopkins University Medical Department, Baltimore, in 1903, and a member of the American Medical Association, the New York State and County Medical Societies, and the New York Academy of Medicine, died at his home on October 22, from septicemia, aged 40 years.

Dr. William Lee McKibben of Amaranth, Pa., a graduate of the University of Pennsylvania, School of Medicine, Philadelphia, in 1869, died at his home on October 12, from injuries received by a fall, aged 79 years.

Dr. Horace William Johnson of Little Rock, Ark., a graduate of the Northwestern Medical College, St. Joseph, in 1886, died in a hospital in Little Rock on October 14 aged 64 years.

Dr. Merari B. Stevens of Defiance, Ohio, a graduate of the University of Michigan Medical School, Ann Arbor, in 1869, and a member of the American Medical Association, the Ohio State Medical Association, and the Defiance County Medical Society, died at his home on October 19, from heart disease, aged 73 years.

Dr. P. D. Spiron of Collinsville, Ill., a graduate of the National Medical University, Chicago, in 1898, died in his office on November 4, aged 50 years.

Dr. Henry L. Gosling of Washington, D. C., a graduate of George Washington University Medical School, Washington, in 1886, died at his home on November 1, aged 61 years.

Dr. Harriet D. W. Showers of Meridian, Miss., a graduate of Cornell University Medical College, New York, in 1900, died in Brooklyn, N. Y., on November 29, aged 47 years. Dr. Showers had been resident physician of the Women's College in Meridian for eight years.

Dr. John Halsey Benjamin of Riverhead, L. I., a graduate of Bellevue Hospital Medical College, New York, in 1876, and a member of the Medical Society of the State of New York, the Suffolk County Medical Society, and the Associated Physicians of Long Island, died on November 26, aged 61 years.

Dr. James O. Green of Long Branch, N. J., a graduate of Bellevue Hospital Medical College, New York, in 1866, died recently in Long Branch, aged 76 years.

Dr. George Douglas Ramsay of Newport, R. I., a graduate of Tulane University of Louisiana, School of Medicine, New Orleans, in 1896, and a member of the American Medical Association, the Rhode Island Medical Society, the Newport County Medical Society, and the Medical Reserve Corps, died at his home on November 27, aged 47 years.

Dr. O. J. Shepardson of Chester, Mass., died in the Springfield Hospital on November 24, aged 64 years.

Obituary.

ALICE MITCHELL, M.D.

WOODSTOCK, INDIA.

DR. ALICE MITCHELL, principal of Woodstock College, India, died after an operation for goitre, at the Augustana Hospital, Chicago, Ill., on Tuesday, November 21, aged 54 years. Dr. Mitchell was born in Morristown, N. J., and was graduated from the Woman's Medical College of the New York Infirmary in 1885. She was appointed an interne in the Presbyterian Hospital of Chicago, Ill., and was the first woman in this country, if not in the world, to occupy the position of hospital interne on an equal standing with men physicians. On the maternal side she was the granddaughter of Dr. Charles Alfred Post of New York City, and possessed by inheritance a strong bent toward surgery. From her father, Rev. Arthur Mitchell, she inherited the initiative, executive ability, the strong faith, and zeal for missions which so characterized her work.

Her experience as a surgeon began at the time of the Haymarket riots in 1886, when explosive bullets were a new weapon in warfare, and many victims of these bombs were brought to the Presbyterian Hospital. During her term of service as interne she was admitted by special courtesy of Dr. Malcolm Gunn to his clinics at Rush Medical College, where the pitiable plight of women who were to be operated on with no member of their own sex present excited her sympathies, and she was able to induce the authorities to allow a nurse to accompany women patients to the clinic operating table—a custom since generally adopted. In 1895 she sailed for India as a missionary under the Presbyterian Board of Foreign Missions, and took the position of resident physician as well as that of an instructor at what was then Woodstock School. Besides the development of adequate care of the sick and preventive measures which reduced the sweeping epidemics which had formerly so often more or less disorganized the school work, her judgment and prompt action at one time checked the spread of cholera which had broken out in the adjoining village and threatened the school when a servant brought the infection there and died of it. As the years went on her time was more and more claimed by the educational and executive side of her work, although she never gave up her medical activities entirely, even when she was finally appointed principal of what is now Woodstock College.

Correspondence.

MEDICAL RESERVE CORPS, U. S. A.

TO THE EDITOR OF THE MEDICAL RECORD:

SIR:—In your editorial comment, issue of October 21, 1916 (Vol. 80, No. 17), you take the viewpoint always taken by the Medical Corps in regard to the Medical Reserve Corps, which relates to the large inactive list of those who contemplate service in time of war only, entirely ignoring the small body of Medical Reserve Officers who have devoted their life to the army active service.

For one reason or another, usually the age limit, they come in as contract surgeons for temporary service (some were captains and majors during the Spanish-American War and Philippine Insurrection with volunteer organizations) and preferring the service to civil practice have remained in on active duty in the Medical Reserve Corps. The inefficients have long ago been weeded out or resigned, and those who have continued on duty (liable at any time to be relieved from active duty) have emphatically made good or they would not have been retained. They are and have been used interchangeably on any duty with captains or majors of the Medical Corps, except that their lack of rank has generally given them the more undesirable stations, and at these stations the most undesirable quarters, as they take rank *after* all other first lieutenants in the army, and a second lieutenant is a rare bird at the present time.

They are the only officers in the army who received no benefit whatever from the recent legislation. The Dental Corps were jumped over the Medical Reserve Corps and given proper recognition, promotion, and retirement. The Veterinarians the same, and the Philippine Scout officers have promotion to captaincies with retirement (these were former enlisted men, and compared with the Medical Reserve Corps officers their educational requirements were trivial). Even the non-commissioned officers of the Hospital Corps gained two new grades of hospital sergeant and master hospital sergeant. The only corps absolutely ignored was the active list of the Medical Reserve Corps. That conditions of their service are unsatisfactory is amply testified to by the number of resignations and requests for inactive assignment among the newer men; the older ones with ten or more years of active service behind them have no practice to return to and so continue to render the same service for which their colleagues in the Medical Corps receive major's rank pay, and prospective retirement.

A bill has been introduced to correct this manifest injustice by commissioning the former contract surgeons who have been active Medical Reserve Corps officers since 1908 as captains in the Medical Corps, but unless the American Medical Association takes an interest in the matter as did the Dental Association for the Dental Corps, and the Veterinary Association for their men, nothing will come of it, and these trained officers of long and excellent service will be lost in the new medical section of the Officers Reserve Corps.

ONE OF THEM.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

MEDICAL SOCIETY PRESIDENT'S ADDRESS—ROYAL SOCIETY OF MEDICINE—OBSTETRICAL SECTION—RENAL CALCULI—ACCIDENTAL HEMORRHAGE—ACUTE TOXEMIA OF PREGNANCY—CESAREAN SECTION WITH HYSTERECTOMY.

LONDON, November 4, 1916.

AT the opening meeting of the Medical Society of London's new session, announced in my last, the new president, Lieut.-Col. D'Arcy Power, F.R.C.S., delivered his address, taking as subject "John Ward and His Diary." This Ward was the vicar of Stratford-on-Avon, whose 16 notebooks are one of the prized possessions of the Medical Society. From them Dr. Severn's extracts made in 1839 have so far been the only authority, so that Mr. Power's further notes on them will be welcomed by all interested by our earlier contributions. They are not ordinary diaries, but would be rather classed as commonplace books of an author residing at Oxford from 1652 to 1660, at which time most of the original members of the Royal Society were also there

resident. Ward was intimate with many of them and seems to have assisted several in their work. His notes, therefore, may be regarded as of special interest as those of a resident graduate at a period of great importance in the university's history. William Harvey was there working with Dr. Bathurst on incubation. Dr. Willis was in practice near Christ Church, with his two assistants (Lower and Wren). Dr. Wallis, friend of Pepys, was working at the circulation of the blood. Barlow was studying oriental languages at the Bodleian. Ward went to London and studied medicine for a year or two, but eventually he entered the Church, and in due course became vicar of Stratford-on-Avon.

At the obstetrical section of the Royal Society of Medicine some interesting specimens have been exhibited and three papers read.

A lipoma of the broad ligament was shown by Dr. Griffith which weighed 13 pounds. At the operation it was found to be retroperitoneal and extended from the right broad ligament to the under surface of the liver. The capsule was incised and the tumor gradually enucleated from above downward. The chief vessels were found down in the pelvis, where the tumor had exposed the right side of the cervix and uterus. The cavity left was closed by a purse-string suture and the abdomen closed without drainage. Good recovery followed. The tumor was composed of adipose tissue and fibrous tissue-strands. Only two other specimens of lipoma of the broad ligament seem to have been recorded.

Dr. Hubert Roberts showed a large calculus of the ureter, removed by abdominal section. It weighed 275 grains. The patient, female, aged 30, had been in several hospitals from the age of 17 with symptoms which suggested renal calculus or tubercle. In 1914 patient was pregnant; after delivery she was not seen until June, 1916, when she was admitted to hospital. The stone was felt as a mass to the right of the cervix, painful to the touch, and fixed. Laparotomy was done and the ureter seen, much dilated and thickened. It was incised after temporary clamping, the stone removed, and drainage made by an opening in Douglas' pouch through to the vagina, uninterrupted recovery following.

A large vesical calculus, 3½ oz. in weight, was shown for Mr. Frank Belben. It had formed round a slate pencil, which the patient, a female of 17, had introduced into the urethra on account of irritation, and it had slipped into the bladder two years ago. It was discovered by cystoscopic examination and removed by suprapubic cystotomy. Another smaller stone was also found and removed at the same time. Some difficulty was met with the larger stone as the bladder had contracted round it and the pencil had ulcerated into the vesical wall, but this was overcome, removal completed, and the patient made a good recovery.

Dr. Hubert Roberts showed an instrument, the invention of the late Dr. Wallace, for opening Douglas' pouch per vaginam, during an abdominal operation.

Dr. Cuthbert Lockyer showed a series of calculi removed from four patients: (1) a small one from the upper ureter removed by abdominal section, incising the pelvis of the kidney, pushing the stone up to the incision, and extracting it. (2) Two calculi from lower end of ureter of a woman aged 63, who was under operation for a uterine fibroid and a solid ovarian tumor. The entire ureter was removed after clamping both ends. A perinephric abscess formed, which had to be opened and drained, somewhat prolonging convalescence. (3) A calculus from a patient from whom previously had been removed the uterus, part of the rectum, and part of the vagina. It had formed at the rectovaginal junction in consequence of an uteric fistula and was removed per vaginam. (4) A large calculus, 5½ inches in circumference, from a case of vesico-cervico-vaginal fistula following a difficult labor. It was removed during on operation for closing the fistula.

Some remarks on this case were made by Dr. H. Roberts, Mr. D. Drew, and Dr. Griffith, after which three papers were read: (1) "Concealed Accidental Hemorrhage with Intraperitoneal Bleeding," by Dr. McNair; (2) "Acute Toxemia of Pregnancy," with accidental hemorrhage treated successfully by cesarean hysterectomy, and (3) "Cesarean Section with Hysterectomy for Accidental Hemorrhage," by Drs. Oldfield, Hann, and Fletcher Shaw.

CANADIAN LETTER.

(From Our Special Correspondent.)

POLIOMYELITIS IN CANADA—COLONEL BRUCE'S REPORT ON CANADIAN HOSPITALS IN ENGLAND — NEW MILITARY CONVALESCENT HOSPITAL AT WHITBY, ONTARIO—MEETING OF THE CANADIAN ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS—MEETING OF THE SASKATCHEWAN MEDICAL ASSOCIATION—A CANADIAN SOCIETY IN PARIS—THE PROBLEM OF THE TUBERCULOUS SOLDIER—OPENING OF A CONVALESCENT HOME IN HALIFAX—PROHIBITION IN MANITOBA—OBITUARY.

TORONTO, November 18, 1916

POLIOMYELITIS, although not by any means prevalent in parts of Canada, is not extinct. New cases continue to crop up here and there. In Montreal and in other points in the Province of Quebec there are several cases. Indeed, the Ontario Board of Health have taken drastic steps to prevent the disease from being conveyed into Ontario. Dr. J. W. S. McCullough, Provincial Officer of Health, has sent the following notice to the railway companies: "Please take notice that the Provincial Board of Health of Ontario requires that all persons under sixteen years of age coming from points in the Province of Quebec to points within the Province of Ontario must have a medical certificate dated within 24 hours of the time of departure that they are in good health and have not been exposed to infantile paralysis. In addition to notifying the railway officials, Dr. McCullough has sent to Montreal Dr. P. J. Moloney, District Officer of Health, to make an investigation of conditions. If the situation seems to demand such a procedure, it is likely that special officers will be appointed to see that the railway companies are observing the order. As to the extent of the epidemic, if it may be termed an epidemic, in Montreal there is no very definite evidence. Official reports, however, show but ten cases.

Somewhat interesting testimony has been afforded as to the ignorance which prevails with regard to the manner in which poliomyelitis may be conveyed. It has been suggested that the disease was brought into Montreal by the agency of dogs from New York. This suggestion was rightly flouted by Dr. C. J. O. Hastings, Medical Officer of Health, who said that while the disease might be transmitted by domestic pets, dogs, and particularly big dogs, are not, as a rule, greatly petted by small

children. He pointed out that in taking precautions against the spread of infective poliomyelitis they were acting not so much on what they knew as on what they did not know.

Col. Herbert Bruce, Inspector General of the Canadian Medical Service, in the course of a report he has made recently with respect to the conduct of the Canadian hospitals in Great Britain and the care taken generally of wounded and sick Canadian soldiers in that country, criticizes the system in vogue inasmuch as there has been no medical inspection by the Canadian Army Medical Service of Canadian Soldiers in Imperial hospitals, and no efficient medical inspection of Canadian hospitals. As a consequence of this neglect Canadian soldiers are retained in hospitals in Great Britain, many of whom should have been returned to duty and others should have been returned to Canada, where they could have been more economically and efficiently treated. Other details of the present system are adversely commented on with regard to the question of segregation for Canadian soldiers, a point upon which particular stress has been laid in the report, opinions appear to differ considerably. However, after all it is a matter which rests almost wholly with the Canadian Government and the military authorities. If segregation is deemed to be to the best interests of the soldiers themselves and consequently to those of the country, then segregation should be introduced and established. New brooms sweep clean and perhaps new brooms were needed so far as the management of the Canadian hospitals in Great Britain were concerned.

The arrangement has practically been concluded whereby the extensive buildings and their equipment known as Whitby Institution for the Insane will be turned over to the Canadian Military Hospitals Commission for the treatment and care of returned soldiers during their period of convalescence. By this arrangement, it is understood, the Whitby Institution, as soon as the buildings already erected are ready for occupancy, will become the centralization point within the Province of Ontario for convalescent soldiers. This is in accordance with the policy of the Military Hospitals Commission to concentrate at a certain selected point within each province the work of caring for convalescent men returned from service overseas.

At the Whitby Institution 1,200 convalescents, or men suffering fram physical disabilities, total or partial, excepting, of course, men with tuberculosis, will be accommodated. The buildings, which are several in number, are beautifully situated on high ground overlooking Lake Ontario, and are especially well adapted in all respects to the purpose for which they will be used.

Slight reference was made in a previous letter to the fifteenth annual meeting of the Canadian Association for the Prevention of Tuberculosis which was held in the Hôtel de Ville, Quebec, on September 12 and 13, under the presidency of Senator J. W. Daniel, M.D., of St. John, New Brunswick. The importance of the meeting, however, calls for a more extended account of its doings or rather the fifteenth annual report of the Executive Council is deserving of closer attention. The report was read by its energetic secretary, Dr. G. D. Porter of Toronto, to whose efforts, by the way, the success of the Association is largely due. Among the many statements of interest in the report is that in 1908 there were only 250 special beds for patients suffering from tuberculosis available in the whole of Canada. In 1911 there were 900, while at the present time there are 2,000 among the various special hospitals and sanatoria throughout the Dominion. The report goes on to state that the necessity for this increase, which is as yet far from sufficient, is most apparent and as the number of returned soldiers who have developed tuberculosis at the front are added to the number already in the country, the need for further accommodations will be still greater. The fact must be borne in mind that the strenuous trying life of the trenches, together with the continual nervous and physical strain of this most modern warfare, the prolonged exposure, and the effects of inhaling the German gases will inevitably in many instances bring on tuberculosis to those predisposed. All these untoward happenings will lower vitality and leave the system open to the invasion of the germs of tuberculosis, or what is far more frequent, will arouse and develop latent seeds of the disease. Colonel Primrose has already reported from the front that in a large percentage of the cases examined, which proved to be tuberculous, it was obvious that an active condition had been engrafted upon a healed lesion. Consequently, there is little doubt that the measures of relief for the tuberculous instituted in Canada in the past will be most useful in the future when a larger number of such cases may be looked for.

The ninth annual meeting of the Saskatchewan Medical Association took place at Regina on July 18 and 19. The meeting was very successful. Dr. George P. Bawden of Moose Jaw delivered the presidential address. Dr. Myers of Saskatoon read an instructive paper entitled "The Returned Disabled Soldier," in which, referring to the problem of providing for the disabled soldier on his return to Canada, Dr. Myers expressed the opinion that the solution of this problem should not be left entirely to the Military Hospitals Commission, but that each individual should take his share of the responsibility. Up to July 13, 1916, 236 disabled soldiers had returned to Saskatchewan and of these 150 required further medical treatment. Dr. Myers thought, when feasible, that crippled soldiers should resume their former employment, and should not be segregated or gathered in large colonies. Occupations in the open, such as market gardening and poultry raising, should be made available for those suffering from arrested tuberculosis and nervous diseases, and small sheep ranches might be established on land given by the government, the money for the purchase of the flock being advanced. He further suggested that a census be taken of all employers of labor in the province and of positions that are or could be made available in the various services of the government. The paper met with the approbation of those present at the meeting and at the business session the following resolutions were passed: "Resolved, that it is the sense of the association in session that the government conduct a census of all available positions of employment within its service and among the employers of labor in the province, with a view to the employment of disabled and unfit returned soldiers. Also that the Saskatchewan Medical Association feel constrained to offer their services to the government for use in the solution of these problems in whatever way the government may see fit."

A Canadian society composed of nurses and medical men has been formed in Paris and meets once a month for the discussion of scientific and medical questions. The first meeting took place on Sep-

tember 4, in the great theater of the Sorbonne under the presidency of Professor Landouzy, the dean of the Paris Faculty of Medicine.

Reverting to the question of the tuberculous soldier, it may be said that so far as those of the Canadian force are concerned, it is regarded by the Military Hospitals Commission as serious. On September 15, Dr. Baldwin of Saranac Lake, Drs. Parfitt and Elliott of Muskoka, and Dr. Byers of Ste. Agathe, met some of the Commissioners to discuss the matter. It was reported that there are at present about 397 soldiers under treatment in the various sanatoria for tuberculosis throughout the country. Nearly 60 per cent of these men have never been overseas. Together with those from overseas and cases which develop in the camps here it is computed that in the spring there will be in the neighborhood of 800 cases to be provided for. As mentioned before in this letter, the accommodation for the tuberculous is fairly good in Canada but not adequate for the many extra cases due to the war. Therefore, arrangements must be made at once to provide for the care and treatment of a large number of tuberculous soldiers.

A convalescent home, known as the Clayton Home, presented by Mr. W. J. Clayton of Halifax, has been opened recently in Halifax, N. S. The event is of particular interest as it is the first institution to be established in Canada for the definite and sole purpose of the educational, vocational, and physical training of disabled soldiers. Statistics got together by Mr. J. N. MacLean, chief of the license inspectors in the province of Manitoba, appear to show that the vigorous enforcement of the Temperance Act there is producing splendid results. Drunkenness is said to have been reduced by 80 per cent.

Dr. Gilbert Tweddie of Toronto died on August 23, in the ninetieth year of his age. He was born in Dumfrieshire in Scotland.

Dr. F. D. W. Bates of Hamilton, a well-known specialist in diseases of the eye, ear, nose, and throat, died after a short illness on August 25.

1. The Physically Defective. Edward O. Otis.
2. Fractures in a Base Hospital. Frederick A. Coller.
3. Speculations Regarding the Pancreas and Metabolism in Diabetes. Hugh P. Greeley.
4. A Report of Three Cases of Typhus Fever. M. G. Berlin.

1. The Physically Defective.—Edward O. Otis, like a great many others, wonders whether any of us are mentally perfect, and suggests that most of us have a mental bias. Fortunately, the "weakest spot" in the majority of men does not incapacitate them for a man's career in the world. Only some marked and glaring physical deviation from what is considered the normal places a person in the category of the physically defective, and this class is what Otis now considers. Mind will triumph over matter, and when the will power is intelligently directed and grimly determined it will make a defective body do its bidding. The men and women, however, who have achieved marked distinction in spite of acquired or congenital physical defects are the exception, for besides the will to succeed, and an exceptional mind, they have usually enjoyed exceptional opportunities for education. Not so with the great mass of the physically defective; but granted that they are of sound mind, much is to be hoped for in their care. The majority can be trained to become self-supporting and to employ the faculties that remain to the best advantage, and thus discount their handicaps. The legitimate duty of the State is to provide for the welfare of its people; and each State must decide for itself in what way and how far it will and can do this. Two fundamental objects are the duty of every well-ordered State: First, to protect its citizens from injurious influences, such as contagious diseases, by controlling pure food, factory conditions, and child labor, etc. Second, to afford an opportunity for development, equality, freedom, and the pursuit of happiness, which is supposed to belong to all in this country as a birthright. The public has largely taken this matter in hand and provided in many cities and States proper measures for the supply of these benefits for the defective as well as the normal individual. While discussing the situation with reference to all defectives, Otis is especially interested in the situation with regard to the crippled and deformed, for whom the States do not appear to have made equal or adequate provision, although this class probably largely outnumbers the other two classes. How many crippled children and adults there are in the United States no one knows, for no census of them has ever been taken. Dr. Orr estimates the number as 259,000, many of them growing up illiterate and without training. The State should supply for these defectives schools and industrial training, whereby they could be made self-supporting and independent instead of a burden. There are only five institutions for crippled and deformed children maintained entirely by State appropriations, one each in Massachusetts, New York, and Nebraska, and two in Minnesota. Some of the similar institutions receive public aid but are controlled and administered by private boards. Otis makes mention of several institutions, especially the Massachusetts Hospital School, maintained by an annual State appropriation of $80,000. The crippled children in the rural districts need help in this direction, and the only institutions meeting this demand are the State institutions of Massachusetts, New York, Minnesota, and Nebraska. At present only about 5,000 of these defectives are being cared for. Apparently they do not make the same appeal to one's sympathies as do the blind, or deaf and dumb. Contrary to this state of affairs, more has probably been done for the blind and deaf than for any other one class of persons. Dr. Alexander Bell showed that there was a minimum of 64,763 blind persons in the United States, of which 8,000 were under twenty years of age. There are forty schools for the education of the blind in the States, with a census of 4,720 individuals; while the 43,812 deaf persons, ninety per cent. of whom became deaf before their twentieth year, many through accident and disease, are taken care of in every State except New Hampshire, Nevada, and Wyoming. Otis makes a plea for the care of individuals who have been made physically defective through cardiac, joint, and other infirmities; that public recognition and provision be made for them in order that they may be able to do useful service through efficient and happier lives.

3. Speculations Regarding the Pancreas and Metabolism in Diabetes.—Hugh P. Greeley offers his ideas on this subject in the nature of a preliminary statement. In discussing it he says that the work of the pancreas, or of its internal secretion, is almost as continuous as the heart-beat, and that almost all the organs of the body are provided with great reserve power; experimentally, one-eighth of a pancreas, or less, is usually sufficient to prevent the onset of diabetes. There is undoubtedly a differing pancreatic function in all of us, varying in the same way as our mental capacities vary; our pancreases are "geared" to a certain maxi-

mum metabolic activity and endurance, and the relation of functional capacity to total metabolism is a mathematical one. Supposing the normal figures are represented by 4/4 pancreatic capacity, covering a metabolic activity of 60 kilos body weight: If the body weight is increased by 40 kilos, the total metabolism requirement would be increased and the functional capacity relatively reduced 66 per cent. The amount of reserve power would determine its sufficiency. Failure of compensation would mean diabetes. In obesity, a similar condition is present, since it may be one of abnormal metabolic function, and is closely related to diabetes. An enormous increase in body weight so increases the total metabolism that the pancreas succumbs to the strain and diabetes ensues. In an opposite way, influences which reduce or retard metabolic activity benefit diabetes. In speaking of the relation of age to diabetes, Greeley shows that diabetes is the severest in infancy and youth and mildest in old age. The remarkable variations in sugar tolerance in the same diabetic individual has been suggested to argue the functional character of the disease. It does not necessarily follow, however. Severe organic disease in any organ is capable of the same variation of function under the sole influence of rest. Herein lies the benefit of the Allen fasting treatment. Greeley cites examples of cases of diabetes in connection with obesity in the adult and the curative effect when the fat was reduced; while in the case of a child with diabetes and relatively high sugar tolerance, with the gain in weight and on total sugar-free diet came improvement in diabetic conditions. He concludes by saying that it remains to be proven whether continuous successful management results in actual regeneration of power of the pancreas. The thyroid and liver are regenerative organs, but the pancreas, up to the present time, has seemed not to belong to this group.

5. The Treatment of Infantile Paralysis. Frank E. Peckham.
6. The Speedy Cure of Tuberculosis. J. D. Gibson.
7. Health Insurance from the Viewpoint of the Physician. Ira S. Wile.
8. The Late Dr. Henry L. Elsner. Charles G. Stockton.

1. The After-Treatment of Infantile Paralysis.—Reginald H. Sayre considers that children who recover full or nearly full function of the muscles after an attack of infantile paralysis have, nevertheless, been through a very severe illness, and should be guarded against too much work, either physical or mental, for several months, as careful examination will show hyperexcitability of the nervous system in many who at first glance appear to be normal. Gordon says that the presence of the reaction of degeneration in the affected muscles is no indication, as it was once considered, that treatment should not be continued and persevered for years after the attack, as he has seen improvement in these apparently paralyzed muscles long after the supposed ordinary time for such results. Where the cooperation of the parents can be secured for a sufficient time, often a matter of years, improvement is often possible. Various methods of treatment may have to be resorted to in the same case: medical, electrical, manipulative, instrumental, and surgical. Strychnine is distinctly helpful in these cases, and should be given in increasing doses until some result is produced or the toleration point reached. Opinions now differ as to the benefits derived from electrical treatment. Gordon has obtained good results from the use of faradism and galvanism. There is no question but that cold, blue extremities are rendered warm and pink by the use of electricity, and subsequent improvement in the patient which would not have come without its use. The strength of the current should be just sufficient to produce muscular contraction; painful applications are unnecessary, and frighten the patient. Manipulations of the muscles are absolutely essential in these cases, but they should never be employed as long as tenderness of the peripheral nerves exists, but after the limbs have become tolerant of movement. Manipulations of the muscles, deep kneadings, rubbings, and superficial strokings are some of the most essential parts of treatment. The patient should be encouraged to make voluntary efforts of the paralyzed muscle or muscles. If the muscles are too weak to respond to the will, the masseur should put the limb through the required motions while the child endeavors to make the limb do the work which the masseur is doing for it. Very little exercise should be given, in order not to produce muscle fatigue, and in little children the same result may be obtained by the use of games. Heat applications by the electric light oven, and artificial congestion of the paralyzed extremity by immersion in a vacuum cup, are beneficial. The question of instrumental support comes up in many cases, and while it is of value in the lower extremities it is of comparatively little value in the upper extremities. It should be light, and should girdle the limb as little as possible, as the muscles are weak, and a heavy apparatus weighs them down. Even when the apparatus is employed other treatment must be continued in order to restore as much function as possible. It is essential that these growing bones should be held in as nearly a normal position as can be done, and deformities prevented, so that the skeleton may be straight. In adapting an apparatus to the deformed leg the joints of the apparatus must move in the same axis as the joints of the leg, otherwise twisting of the foot may result. Braces should be discarded as soon as the patient is able to balance and walk without the support. If the lower extremities and spine are both affected, and the paralysis persists, the patient is best treated in a wire cuirass, in which he can be carried about much like an Indian papoose. He considers the number of cases which are amenable to surgical treatment is comparatively small, but wonderful help can be given these few cases. Surgery is useful when tissues which are contracted can be elongated, but not otherwise. Subcutaneous tenotomy may be employed. The results of immediate suture of nerves in infantile paralysis has not been very successful. Bone operations to restore function must be done only on selected cases, as there is much to be taken into account, such as expense, time, and ultimate result in comparison to the relief given by prolonged treatment and braces. Gordon concludes as follows, after thoroughly discussing the different types of deformity which may require bone operation: "Do not do too much at first; give the patient absolute rest for many weeks. Prevent deformities by opposing contracting muscles. Later on use gentle massage movements, active, passive, and restrictive. Endeavor to re-establish the path of nerve control to the muscle. Aid this by electric stimulation in suitable cases. If necessary, employ support to prevent undue stretching of muscles or ligaments, or deformity of bones. Later on, if deformities have developed, do such surgical operation as may be necessary to put the skeleton in a position best to support weight, and to balance the opposing force of muscles so as to preserve equilibrium. By these means many patients who

otherwise would be hopelessly bedridden will be enabled to go about in comparative comfort."

5. Care of Troops on the Mexican Border.—Weston P. Chamberlain gives an account of his four months' medical experience with an army of one hundred and fifty thousand men, otherwise the part of the militia ordered to the Mexican border. He considers that the mobilization clearly demonstrated many of the weak features in all branches of our militia system, but he refers chiefly to the sanitary features, and states some of the lessons learned from the mobilization, as follows: 1. The physical standards of the regular army should be strictly applied to the members of the national guard. 2. All members of the national guard should be immunized against smallpox, typhoid, and perhaps the two paratyphoids, at time of enlistment. The former two procedures should be repeated in three or four years. The length of time the paratyphoid vaccination will protect remains to be worked out. 3. The states should organize sufficient ambulance companies and field hospitals to bring the allowance of each unit up to at least four for every authorized division of state troops. All sanitary equipment should be kept complete, serviceable, and up to date. 4. The medical corps of the regular army (even when it reaches after four years the recently authorized allowance of seven per thousand of strength in the army) will be insufficient to provide adequately for the needs of any such force as would be required in a war of the first magnitude. 5. Consequently, adequate medicomilitary training should be given to the militia sanitary organizations and to the Medical Reserve Corps. 6. The Medical Reserve Corps should be greatly increased in size—to 10,000, or perhaps 20,000. There were approximately 1,600 men in the corps last summer, and from these it has been difficult to get 350 for active service. Few wish to remain long on active duty. 7. Typhoid fever need no longer be dreaded as a scourge to armies. 8. State troops can be maintained indefinitely in camps in the South, and at the same time remain in excellent health, provided certain simple sanitary precautions are continuously and rigidly enforced. These precautions will not be continuously and rigidly enforced unless alert and experienced sanitary inspectors are placed in charge and vested with sufficient powers to enable them to compel the prompt correction of sanitary defects.

9. Bilateral Charcot Hips, Occurring Simultaneously—S. J. Wolfermann reports this case because Charcot's disease in both hips simultaneously is unusual, and to emphasize further the long period of latency of some syphilitic infections. The patient, a mechanic, aged 42, married, had always been healthy, and wife had borne two healthy children. He had had gonorrhea twenty-five years ago, with a nonsuppurative bubo. In 1891 there was a single hard chancre, and he was treated with baths; no secondaries were noticed, and there was no skin or ulcer. During the fall of 1912 he began to have "rheumatic pains," limited to the areas below the knees, these pains occurring only at night and usually along the inner side of the tibia. They occurred intermittently for about one year, and without any other treatment than the baths he became apparently well. Two other attacks about six months apart came on, the second one lasting about a month and the pain extended up the thighs, with a grating in the left hip, which symptom now appeared for the first time. Two months later the left leg felt "asleep" and became useless. The next month, September, the darting pains appeared in the right thigh, which became markedly swollen, but not affecting the right hip, while the right leg became useless. During October he experienced "a feeling of pressure toward the center at the waist." After physical examination the diagnosis formulated itself: "Lightning pains," suggestion of girdle pain, beginning sphincter weakness, hyperesthesia, loss of knee reflexes, Argyll Robertson pupil and bone destruction without pain or temperature was assuredly beginning tabes with two Charcot hips. Wolfermann adds that at this time, after a considerable amount of treatment with mercury, iodid, and arsenic, the grating is practically gone, hyperesthesia is diminished, and there are no bladder symptoms. Treatment is continued in view of later attempting to make new hip joints, if a negative Wassermann reaction can be obtained.

10. Coagulation Time in Lobar Pneumonia.—J. M Anders and George H. Meeker state that it is common knowledge that the time necessary for coagulation to occur is variable and depends on many conditions, and that bacteria and their toxins play a role in the coagulation process is undoubted, but their significance is not definitely known. The subject of the relation of infection to coagulation has been discussed by several modern writers, and, on the whole, the weight of authority is in favor of the view that infectious diseases retard coagulation. When normal blood coagulates, "about 0.1 to 0.4 per cent. of its weight separates as fibrin" (Krehl). In certain diseases, especially those accompanied by inflammatory exudates (as lobar pneumonia and pleurisy), a marked pathologic increase up to 1 per cent. or over may be found. In certain infections, notably typhoid fever, no increase is observed, although intravascular clotting is more common in this disease than in lobar pneumonia, if we except the large so-called marantic thrombi found in the great vessels after death. That the quantity of the fibrin factors has nothing to do with either extravascular or intravascular clotting is further shown by the fact that they are present in normal amount in hemophilia (Litten, Sahli). The coagulation time is found to be shortened after hemorrhage (severe pulmonary hemorrhage, hematuria), in carcinoma of the uterus, in abortion, after transfusion, in endocarditis, in dementia precox, and

after the administration of gelatin. The total number of observations was 138, and the coagulation time ranged from one minute to six minutes and twenty-five seconds. On the other hand, 100 tests on healthy individuals showed the coagulation time as distinctly longer in them than in lobar pneumonia, the mean difference being one minute and fifty-five seconds. They draw the following conclusions from their experiments: 1. The coagulation time is somewhat shortened in lobar pneumonia. 2. The cause or causes of this abbreviation are not definitely known. 3. The influence of a meal on the coagulation time is trivial, but practically constant. 4. The effect of the administration of calcium salts on the coagulative process must be quite inconsiderable. 5. The calcium present in the blood in lobar pneumonia does not exceed the normal amount.

2. Further Cases of Kala-azar in Europeans Successfully Treated by Intravenous Injections of Tartar Emetic.—Rogers, together with Hume, reported last February on six cases of kala-azar in Europeans treated by this method, with recovery in five and death from phthisis in one, after the kala-azar germ had disappeared from the spleen. During the last fourteen months they have treated eighteen new cases with remarkable success, and have been able to shorten considerably the time required for effecting a cure by increasing the doses more rapidly than they ventured to do at first. Reports on twelve cases are given showing the expected results, and in no case that they have been able to follow up from four to twelve months has there been any relapse. With reference to dosage, they now recommend adults to begin with 4 c.c. of the 2 per cent. solution of tartar emetic, to add 2 c.c. at the second injection, and, if no toxic symptoms occur, 1 c.c from that point to 8 or 10 c.c., above which it is not necessary to go. In patients with dropsy or albumin in the urine the dose should be increased cautiously, and in any patient, if toxic symptoms arise, other than cough, immediately after the injection, the dose should be reduced until no sickness or nausea occurs. In the majority of cases the injections have been continued for from several weeks to two or three months after the fever had ceased, and only stopped, as a rule, when signs of full recovery had appeared, such as increase in body weight, reduction in size of the spleen, an approximately normal blood, and when the parasites had disappeared from the spleen. When it is remembered that the most reliable data regarding the mortality of kala-azar under careful and prolonged treatment showed a mortality of 96 per cent. the results now obtained by Rogers and Hume are so remarkable that Rogers suggests that it is difficult to find a parallel case in which such a deadly and lingering disease has been brought under complete control by a simple medicinal remedy. The author further suggests that the use of tartar emetic appears to be worthy of especial study in cases of human trypanosomiasis and of sleeping sickness in Africa.

3. Dental Disease in Nursing Women.—Harold Waller gives a report of a successful outcome in a series of his cases in which deficient lactation in nursing women was due to oral sepsis. This does not mean that dental sepsis is responsible for all cases in which the child fails to thrive on the breast milk. But in the cases to which he has reference dissatisfaction with the breast feeds and vomiting are among the early symptoms, and the vomiting is of an intractable type, occurring at frequent, varying intervals, and is copious and forcible. The child loses weight, and there is a persistent blueness of the extremities quite foreign to one whose diet and digestion are in accord. Where there is a gain in weight it is unsatisfactory. The appearance of the mother may suggest ill health, for she often looks wan and frail, but not in all cases. It will be found upon inquiry that evidences of metastatic effects of oral sepsis will be given unsuspectingly. It is common to be told that the woman is rheumatic and is subject to recurrent sore throat. Attacks of neuralgia, stiff neck, gumboils, indigestion, vomiting, loss of weight and strength are complained of. Inspection ofttimes shows caries of the teeth, broken roots, probably covered with plates, and discharging sinuses, and loose teeth with a copious discharge arising from their alveolar processes. A chronically infected state of the tonsils must be added to the list. For years medicine has been resorted to for the debility and anemia. Cases presenting greater difficulty are those in which elaborate dental work has been done, covering up the true condition of the teeth and gums. The real importance of the question lies in the chance which treatment offers of effecting a sufficiently rapid improvement in a woman's health to raise her powers of lactation from a subnormal to a satisfactory level, and so avoid the need of artificial feeding for the child. The prevalence of this condition must be regarded as a disastrous one, claiming attention on national grounds of the first importance, in view of the interference it produces with the course of infant welfare. Waller found that the results obtained after proper or even inadequate attention had been bestowed upon the dental condition of the mother were (1) the increased rate of gain in the child's weight and (2) the length of time over which nursing can be carried should be prolonged. Also greatly improved health in the mother, with increased flow of good milk; a cessation of dyspeptic symptoms in the child, with general systemic improvement. Three cases are given, one of which describes the condition of the first-born of a woman of 29 years. The mother appeared healthy, but the baby at three and a half weeks of age began to waste away and gave the typical blueness of the extremities. While the mother's milk was copious, the child continued to grow worse. After careful dental treatment had been instituted in the mother the child's skin improved in color, the weight, which had been stationary at five pounds from the third to the tenth week, rose to ten pounds between the tenth and eighteenth week. The particular cases illustrative of this condition were chosen from nearly 200 in which dental sepsis interfered with the power of nursing an infant. Improvement capable of registration was achieved in 80 per cent., the remainder were nearly all lost sight of and did not complete the treatment. Waller suggests that it follows from what has been reported that the earlier treatment is obtained the better. It is difficult to suppose that a condition which can influence a child so profoundly through its parent after birth can fail to exert effects during intrauterine life. Research into the association between dental disease and the occurrence of miscarriage and the birth of premature infants of weakly physique might well produce important results.

1. The Possible Function of the Cerebrospinal Fluid.—W. D. Halliburton, in an address before the Neurological Section of the Royal Society of Medicine, gives the normal characteristics, composition, and fate of this fluid and its pressure. In speaking of the means of communication between the cerebrospinal fluid and other parts of the body, or rather the lack of it, he calls attention to the fact that Dixon and he found that dyes added to the fluid travel along the course of certain cranial nerves, especially the olfactory nerve. Such is not the case with the spinal nerves; no dye can be detected in their sheaths outside the spinal canal, and no dye is discernible in the lymph of the thoracic duct. Clinically the olfactory outlet is important as it affords an opportunity for the entry of infective agents. He draws attention to the apparently analogous relation of the cerebrospinal fluid and lymph, but while the essential feature of a true lymph is the free interchange between it and the blood in both directions, this is lacking in cerebrospinal fluid; at least it appears to be permeable to substances passing from it to the blood, but impermeable (except for oxygen) in the direction from the blood to the fluid. Halliburton says that he has been led to take the following view: The nervous mechanism being so sensitive, so easily influenced by anything unusual, the neurons must be bathed in an ideal physiological saline solution to maintain their osmotic equilibrium; the trace of protein it contains is probably quite sufficient for nutritive processes. The sugar would serve for a supply of energy. The choroidal epithelium is really exercising a protective function by keeping out harmful proteins (toxins, etc.), while some harmless ones are kept back almost completely; all share the same process of exclusion. This protective action also applies in addition to the majority of soluble drugs; this may operate so as to be detrimental in diseased conditions, but one can hardly expect discrimination on the part of the epithelial secreting cells. The nonaccess of metallic and other poisons to the nervous elements is such a *sine qua non* for their health that during those periods when such substances are given for the relief of disease or the slaughtering of parasites the choroidal cells are unable to change their habits, and so do not allow the drugs to get through. Such, Halliburton states, he believes to be the real significance of this remarkable secretion.

5. Note on a Case of Jaundice from Trinitrotoluol Poisoning.—Hugh Thursfield reports a case of a woman thus poisoned, and calls attention to the fact that only since the war have we known of the toxicity existing from the manufacture of explosives belonging to the group of the nitro-derivatives of benzine and toluene. Drowsiness, headache, and nausea, varying degrees of cyanosis, with anemia and jaundice, and in some of the cases of jaundice a proportion have proved fatal. Such was the case Thursfield cited. This young woman, strong and healthy, had been employed in munition work for about six months, and four months before her fatal illness became an examiner in a munition factory. She examined bags filled with the yellow powder, hence the atmosphere was powder laden. She tasted it even in her food. She wore a plate in the upper jaw and always cleaned it after meals, but never before eating. One month before her illness she noticed she was passing dark-colored urine, but did not feel ill until two weeks later. She complained of headache and nausea and loss of appetite. She became worse, and was taken to St. Bartholomew's Hospital. She was deeply jaundiced, and the urine was almost black with pile pigments. Her temperature was normal, and aside from the jaundice and vomiting she did not appear to be very ill. Two days later, however, she became drowsy and vomited excessively, and in two days, after delirium had set in, she gradually sank, and died in the evening. Autopsy showed fatty-degeneration of the liver and kidney tissues, with petechial hemorrhages in the pericardium, viscera, and parietal pleuræ. The history and course of the illness are those of an acute toxemic jaundice, nonobstructive in character, but the blood examination showed a normal condition, with 5,000,000 red cells per c.mm. and hemoglobin 90 per cent. This was rather remarkable in view of the fact that trinitrotoluol frequently causes anemia. Clinically, the most striking feature of the case was the suddenness of the onset of the fatal symptoms, for in less than two days before her death she seemed to be in good condition, without any serious symptoms pointing to a grave prognosis. Yet it was obvious at the time of the autopsy that the toxemia had already robbed her of any chance of survival.

7. A Simple Aseptic Way of Performing Vaccination.—Echlin S. Molyneux offers a method of vaccination which he has employed on recruits with good results. He suggests that while it may appear to seem laborious, with but a little method in handling the individuals, it is not so. He vaccinated 180 men in 231 minutes, or well under two minutes each. Each roll of gauze ten yards long sufficed for from twenty-five to thirty men, so that the expense was not great. Out of this number of vaccinations very few inflamed arms appeared, and the slight inflammation was soon reduced by boric-acid solution applications. The technic is as follows: (1) The patient's arm is first thoroughly rubbed by an orderly with methylated spirit to disinfect the skin. (2) A tube of calf lymph is taken and one end broken off; the broken end is held for a moment in the flame to sterilize it, as it may touch the patient's skin during the operation. A lighted match is then applied to the other end of the tube of lymph, which always contains an air bubble. The heat of this causes the air to expand, and, if held over the patient's arm, it blows the lymph on to the arm. (3) A needle is taken with a point that has been slightly blunted, and held for a moment in the spirit flame to sterilize it. The lymph is spread from the drop on the patient's arm with the sterile needle to as many points as it is desired to vaccinate, usually four. The skin is then scratched by the needle sufficiently to draw a little of the patient's lymph, but not sufficiently to draw blood. (4) A pad of sterile white gauze is immediately and firmly strapped on in the following way: A towel, wrung out in 1 in 40 carbolic, is spread out on a table, and on it is a roll of sterile gauze ten yards long. A piece of gauze is cut off and folded twice or three times and applied to the patient's arm in such a way that the inside of the gauze comes next his skin, and no part which has been touched by the operator's fingers lies near the vaccination wounds. Then a strip of 1-in. adhesive plaster is wound round and round the arm over the dressing to keep it secure. (5) The patient is told on no account to let the dress-

ing get loose, and to have it dressed immediately should it show signs of slipping. He is ordered light work not necessitating using his arm, and he is directed to come up in five days. The second and any subsequent dressings are of boric lint.

Amebic Dysentery.—Mauté has studied this condition as it occurs in Morocco. At Fez it is endemic. Without giving the details of his studies, he proceeds to his results. Intestinal amebiasis is a chronic affection with acute exacerbations. The dysenteric crisis is only an episode in the course of the disease. If after injections of emetine the stools become formed, this does not mean that the bowel has become sterilized. This statement cannot be too strongly emphasized. The usual practice is as follows. When the stools have become normal the emetine injections are renewed (1 to 3 injections) and the patient kept under observation for about a fortnight. If there are no signs of recurrence he is discharged "cured." This custom is very dangerous, not only for the patient himself but for those about him. It has recently been shown that carriers of amebic cysts transmit the disease. In 8 cases out of 10 so-called emetine cures the author has found these cysts in the stools. The latter must be persistently followed up. If finds continue negative, a provocative test should be made. The author has succeeded best with iodized water 1:1000 (1 gm. iodine, 2 gms. iodide per liter of water). The injection should be given in the morning, and two or three hours later the patient will expel amid some gripes a certain amount of mucus filled with cells of all kinds. In rare cases the ameba will be present, both in the cysts and as free bodies, even in cases which have seemed to be cured for weeks and in whose spontaneous stools no parasite can be discovered. From another angle, amebic dysentery may be overlooked because of its mild character. In such cases, hepatic abscesses are more prone to develop than in the more severe forms; in fact, the abscesses may even seem to be spontaneous. In an endemic *milieu*, every intestinal derangement should be suspected and researches instituted. At Fez, in addition to the *Amœba histolytica*, the author found the trichomonas and other protozoans, and intestinal worms (triscephalus, ascaris). As these parasites appear to cause a sort of mixture of infection or symbrosis which is hostile to a good prognosis, santonin should be given as a vermifuge. Turpentine is said to be active against the protozoans. It is impossible to determine the duration of the evolution of intestinal amebiasis. In 22 per cent. of cases the author has seen the cysts disappear by the fifth week, and in 72 per cent. from the fifth to the tenth week. In 6 per cent. the disease was especially refractory, and failed to yield under emetine-arsenic treatment. Chlorhydrate of emetine is a veritable specific against the dysenteric crisis. If the diarrhea persists this is commonly due to the presence of worms or the trichomonas. The post-dysenteric management has already been outlined. Everything depends on a good quality of emetine. In refractory cases neosalvarsan treatment may be added.

Correspondenz-Blat für Schweizer Aerzte.

October 28, 1916.

Sepsis Lenta.—Deus refers to Schotmüller's discovery in 1903 of the activities of the streptococcus viridans. The latter, as is known, can cause either acute or insidious sepsis. In order to account for this twofold pathogenicity, Steinert laid down the law that insidious cases occurred only in rheumatic subjects; in other words, acute viridans sepsis may only attack subjects who have not been partially immunized—for we must look upon the rheumatic subject as enjoying a certain degree of protection. Another theory not involving the presence or absence of immune bodies is the saprophytic, according to which the viridans is essentially harmless but under unknown conditions may be roused to different types of pathogenicity. These two theories do not antagonize each other. The saprophytic view is reasonable and one acute attack of sepsis might well confer some immunity. Still another theory—anaphylaxis—might be called upon to explain why a mild attack of viridans sepsis could be followed by an acute outburst. Acute viridans sepsis usually takes its origin from the female genital. Especially fulminating cases are seen in connection with infected abortion. The viridans has been known to cause erysipelas and may complicate tetanus and diphtheria. The author describes a personal case in a man of 37 who had never suffered a rheumatic attack. About 18 months before consultation his health began to fail without apparent cause. Six months later he developed pleurisy with effusion, which, despite repeated puncture, did not permanently subside. Later ascites followed and dominated the entire disease picture. The general state grew progressively worse, and death ensued with the picture of failing heart and dyspnea. The autopsy finds are given in great detail. The entire picture was due to the lesion of the heart, and this is summed up as follows: An isolated endocarditis limited to the cardiac wall, and covered with organized fibrin, the valves being fully intact. In the right ventricle the process was undergoing resolution, while on the left side, despite evidences of present acute inflammation, a tendency in the same direction was noted. The absence of notable virulence and the consequent slow march of the process goes hand in hand with the progressive fibrous organization of the thrombi. Despite the venous stasis in the viscera the action of the heart was good and could be likened to that seen in well-compensated organic disease. The cardiac finds, while unique in this instance, differed only in degree from those usually encountered, in which valvular endocarditis occurs. In this case the inflamed ventricles presented dense adherent masses of organized fibrin. In various viscera in addition to the phenomena of stasis were found septic emboli. Save for the heart the anatomical picture was typical of sepsis lenta. Clinically the nature of the case was such that a bacteriological test of the blood was omitted. There is no intimation as to the source of the infection.

La Riforma Medica.

October 23, 1916.

Oxaluria Is Not a Disease of Metabolism.—Fittipaldi sums up a study of this subject as follows: Oxaluria as a disease cannot be due to an excess of oxalic acid or the oxalates in the food. There is no relationship between oxaluria and diabetes or between oxaluria and obesity. The coexistence of oxaluria and urticuria is of no significance in connection with the origin of oxalic acid. An excess of the latter, isolated from the blood in oxaluria, does not mean an oxalemia. There is no connection between oxaluria and gout when oxaluria appears because of deficiency in tissue respiration; it means that the sources of the acid have not been sufficiently oxidized in the blood. Oxaluria is not a disease of metabolism. but doubtless results from an enterogenous intoxication due to some specific enzyme as yet unknown.

Lactic Bacteriotherapy of Wounds.—Colombini, in writing on the sterilization of wounds, with special reference to the prophylaxis of tetanus, speaks favorably of the lactic acid bacteriotherapy of wounds as carried out in the Hospital of the Experimental and Bacteriological Agrarian Station at Crema. A liquid previously fermented is employed, consisting of whey and peptone, containing the products of metabolism of the lactic acid bacilli. Lactic acid is formed to the amount of 1 per cent. Owing to temperature conditions, living cultures cannot be used in wounds. This necessitates the practice of fermenting a substratum with cultures. Lactic acid is not the only product of bacillary metabolism. The mixture has striking anti-putrefactive properties and is able to cleanse an infected wound thoroughly in a few days. Whatever the theory may be, the fact remains that infected wounds have later been shown by the microscope to be sterile. A simple 1 per cent. solution of the acid exhibits no such properties. There is nothing which points to commercialism, as the liquid is prepared at a Government Experimental Station for Agriculture, which doubtless supplies details to any one interested.

Alcoholism in Italy.—M. L. reviews Professor Bianchi's recent memorial on this subject. Alcoholism in Italy is a problem in itself. There is an enormous production of wine, consumed mostly at home. Its use is a matter of tradition and custom. It is regarded as food, despite its small nutritive value. The author marshals the leading arguments advanced as to the essential harmfulness of alcohol by writers outside of Italy. In the latter country both acute and chronic alcohol poisoning are seldom met with. The author in thirty years of activity in Palermo and Naples has seldom seen delirium tremens. On the other hand, it is not impossible that a slow, insidious alcoholic intoxication of the Italians has been taking place through the centuries. This is chiefly in evidence in the greatest wine growing countries. It is rather a feeling that this is the case than anything demonstrable. There seems to be a subnormal efficiency in the worker, due to lack of endurance or persistency, and there is an abnormal tendency toward litigation. Alcohol must play a very small role in acute psychoses, but seems in evidence as a casual factor in various affections and attributes—epilepsy, delinquency, idiocy, arthritism, obesity, indolence, indifference, excitability, impulsivity, irascibility, etc. In the Northern countries this problem of racial characteristics does not exist, and is in part replaced by that of the excessive use of alcohol during short periods of time—something unknown in Italy, as is also the use of industrial alcohol as a beverage with the dangers of a methylism. The author from his immense experience with wine drinkers is able to detect much exaggeration in articles which emanate from the North. The amount taken daily and the proof of the wine are of great practical significance, as is also the vocation or absence of one. In other words, there is a utilizable limit. The alcohol percentage of the native wine varies from 10 to 14 (no other kinds are mentioned) and the use of small amounts with meals only is regarded as innocuous. A "small bottle" of wine which contains from 20 to 30 gms. of alcohol answers this requirement. Anywhere from 40 to 70 gms. alcohol daily is regarded as the limit of safety beyond which a definite action on the nervous system may be perceptible. A daily consumption of from 300 to 600 gms. of wine means the same thing. Aside from defending the minimal use of wine as not only innocuous, but even perhaps salutary, Bianchi's conclusions do not differ essentially from those of Northern writers.

La Riforma Medica.

October 30, 1916.

Diagnosis of Malignant Tumors of the Liver.—Ferrannini mentions a number of cases occurring in the past five years in which the diagnosis was made by necropsy, biopsy after exposure of the liver or borings. The necropsy in a woman of 63 showed the pressure of an endothelio-sarcoma. The organ weighed 3,100 grams and before section presented hardly any evidence of tumor formation. Upon section numerous tumor masses were seen. The stomach was normal, but the left kidney was greatly enlarged from the same disease process. Very small metastases were found within the thorax. No primary lesion is mentioned. In a man aged 55 there was ascites of high degree. Instead of a paracentesis laparotomy was at once performed, in order that the liver might be examined. Five liters of fluid escaped, and the liver was found to be the seat of numerous nodules. Attempts at aspiration ended negatively, showing that the latter were solid. There was a history of very severe, painful crises over the liver before the appearance of ascites. The latter by causing dyspnea led the patient to seek relief. The diagnosis of malignancy having been made, a systematic search for lymphnode metastases was begun, with negative results. There was, however, a notable failure of general health, of the type which suggests malignancy. The peculiar tint of the cancerous patient was missing, as was also the yellowish-gray color believed to be common in sarcomatous patients. The blood count was not suggestive of malignancy. Hydatids and tertiary syphilis had been excluded. As between sarcoma and primary cancer the evidence pointed rather toward the former, chiefly because of the absence of regional lymphnode metastases, especially in the left supraclavicular fossa. Sarcoma, so-called, of the liver comprises perithelioma, endothelioma, cylindroma, lymphosarcoma, and other subvarieties. There appears to have been no autopsy on this patient, as the author leaves the exact diagnosis to be worked out by clinical evidences. When the liver was inspected by laparotomy, lymphnodes as large as a walnut were seen in the omentum and retroperitoneal space. The evidence, however, leaned toward sarcoma, because of the absence of external lymphnode metastases and icterus.

Tuberculous Meningitis Simulating the Prodromic Period of Multiple Sclerosis.—Cammarata relates the following case: The patient was a boy aged 3 years, of good family and personal antecedents. Six months before consultation he exhibited a tremor of the right hand, worse in the daytime. Three months later his right leg lost its feeling and he walked with a tremulous, spastic gait. On examination he showed an intention tremor and could not raise a glass to his lips unless aided by the left hand. Meningitis could be excluded completely. Diagnosis, sclerosis *en plaques*. Some weeks later he was attacked by fever, headache, and vomiting, stiff neck, convergent strabismus, terminating after a few days in convulsions. Lumbar puncture was now practised. The fluid emerged under strong pressure and the sediment contained tubercle bacilli. There was some temporary improvement, but death followed an exacerbation. Autopsy was refused. The connection between the early symptoms of sclerosis and the meningitis was obscure. Sachs describes an abortive type of the former, which, however, is extremely rare at so early an age. By exclusion it is quite impossible to reach any other diagnosis. Cammarata suggests that a possible compromise diagnosis would be a focus of tuberculous meningitis behaving like a patch of sclerosis.

Book Reviews.

PYE'S SURGICAL HANDICRAFT: A Manual of Surgical Manipulations, Minor Surgery, and Other Matters Connected with the Work of House Surgeons and Surgical Dressers. Edited and largely rewritten by W. H. CLAYTON-GREENE, B.A., M.B., B.C.(Camb.), F.R.C.S. (Eng.). Surgeon to St. Mary's Hospital; Lecturer on Surgery in the Medical School, etc. Seventh Edition, Fully Revised, With Some Additional Matter and Illustrations. Price $4.50 net. New York: William Wood and Company, 1916.

THIS has ben a standard work for more than a quarter of a century and shows no sign of waning popularity. For this, the seventh, edition the subject matter has been thoroughly revised and considerable portions practically rewritten. While originally designed especially for the instruction of members of house staffs, it has gradually reached a far wider field of usefulness; and while still satisfactorily fulfilling its original design it has been amplified to a degree that renders it a valuable aid to the general practitioner also. This will be appreciated by noting the headings of the various sections. There are 53 chapters embraced in ten sections, the titles of which are: The arrest of hemorrhage; Apparatus for restraint and support (bandages, splints, etc.); Fractures, dislocations, and sprains; Wounds, ulcers, and burns; Cases requiring prolonged or mechanical treatment; Minor surgery and kindred subjects; Special cases connected with the head and throat; Certain emergencies, surgical and general; The administration of anesthetics; Miscellaneous. Under the latter heading there are chapters on the preparation of patients for operation and their after-treatment; the making of poultices, fomentations, etc.; urine testing; *x*-rays in diagnosis and treatment; and surgical history taking.

Upon looking through the work we find that there are many instances where procedures recommended are quite different from customary methods here yet are unquestionably good; and that a knowledge of them, as well as of the more common methods, cannot fail to add to the efficiency of the reader. On the other hand, we occasionally find that American methods are far in advance of those recommended in this work. For example, in the chapter on hemorrhage and transfusion we find the method for continuous saline flow into the rectum far inferior to the technique of the Murphy drip; while the discussion of transfusion itself is quite out of date according to our standards. The discussion of the truss treatment of hernia is generally poor, while we consider the advice given regarding the treatment of undescended testicle to be wrong.

The chapters on surgical emergencies and the treatment of various poisonings contain many valuable suggestions, and the same applies to that on pre- and post-operative treatment and many others too numerous to mention specifically. It is certainly not too much to say that while former editions of this work deserved popularity, the present revision and extensive rewriting should add greatly to its prestige.

THE PROBLEMS OF PHYSIOLOGICAL AND PATHOLOGICAL CHEMISTRY OF METABOLISM. By Dr. OTTO VON FÜRTH, Professor Extraordinary of Applied Medical Chemistry in the University of Vienna. Authorized Translation by ALLEN J. SMITH, Professor of Pathology and of Comparative Pathology in the University of Pennsylvania. Price, $6. Philadelphia and London: J. B. Lippincott Company, 1916.

IN its original form this work of Fürth's has been familiar to many workers in biochemical fields as one of the most satisfying treatises on metabolic chemistry. The subject has become so complex in its ramifications that it is most useful to have a comprehensive summing up of the present state of knowledge in this direction, and the series of lectures here offered in printed form is designed to give a résumé of what may now be considered as fairly definitely established in regard to the underlying reactions of vital processes. Even the most seasoned plodder through scientific literature at times welcomes a journey that leads over less arid regions than usual, and the present volume is decidedly entertaining, as well as instructive, for its lecture character has enabled the author to adopt a somewhat easier style than is customary in purely technical works. The translation is very close, yet its form is admirable, and it is only rarely that some twist of phrase has been allowed to remain as a reminder of the syntactic peculiarities of the original. It was certainly the part of wisdom to choose first the latter of the author's two volumes for presentation to the English reading public, for the former of these, which is devoted to cellular chemistry, is much more technical and of less appeal to the general reader. In the present volume, as its title indicates, the problems of metabolism as a whole are discussed, both in relation to the normal processes, and as encountered in various diseases depending on disturbances of the body's chemistry. While in some instances not all of the latest work is included, as for example under diabetes and proteid metabolism, for the lectures on which the book is founded were delivered at the University of Vienna before 1911, yet there appears to be little of importance that has been omitted, and the book will undoubtedly be found of great value by all who are interested in this fascinating but difficult study. It is to be hoped that the translator will extend his labors also to the production of an English version of the first volume.

NERVOUS DISORDERS OF MEN. The Modern Psychological Conception of Their Causes, Effects, and Rational Treatment. By BERNARD HOLLANDER, M.D., Author of "The Mental Functions of the Brain." Price, $1.25 net. London: Kegan Paul, French, Trubner & Co., Ltd.; New York: E. P. Dutton & Co., 1916.

THE title of this book is somewhat too general, the author modifying it in the preface by limiting himself to functional disorders. It is addressed to the lay public and to the less well-informed members of the medical profession. The first part is largely occupied with an account of "nervousness" somewhat in the vein of Dr. Stephen Crane or Herbert Kaufman. Various neuroses, psychoneuroses, and anxiety states are grouped by the writer under this head. No attempt, of course, is made to explain phobia, obsessions, etc., by any of the newer psychological methods. In fact, the medieval explanation is the one adopted. In a chapter devoted to the "semi-insane," a brief description is given of cyclothymia and hypomania. Galvanism and psychotherapy constitute the author's therapeutic armamentarium. If the patient has pains in the stomach he applies the current to the stomach; if he suffers from any general nervous condition, it is applied to the spine.

NERVOUS DISORDERS OF WOMEN. The Modern Psychological Conception of Their Causes, Effects, and Rational Treatment. By BERNARD HOLLANDER, M. D., Author of "The Mental Functions of the Brain." Price, $1.25 net. London: Kegan Paul, French, Trubner & Co., Lt.; New York: E. P. Dutton & Co., 1916.

THIS book is a companion volume to "Nervous Disorders of Men," elsewhere reviewed, and many of the chapters differ from the first book mainly in a change in gender of the pronoun. Some discussion is given in the introductory chapter to the difference between the nervous systems of men and women. There is a chapter of psychoanalysis which, while superficial and dealing in generalities, is quite readable and probably better for the lay public than much about this subject which is accessible to it.

A MANUAL OF FIRE PREVENTION AND FIRE PROTECTION FOR HOSPITALS. By OTTO R. EICHEL, M.D., Director, Division of Sanitary Supervisors, New York State Department of Health. Price, $1. New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Ltd., 1916.

THE preface states that it is the purpose of this manual to provide in convenient form an outline of the principles of fire prevention and protection with indications for their application in institutions housing the sick. It is planned for use, not only by superintendents and boards of managers, but also by inspectors, architects, builders, and others who have occasion to consider the fire problem in hospitals. It is to be hoped that the book will have wide use, and that further study by those active in hospital management will be stimulated.

COLLECTED STUDIES FROM THE BUREAU OF LABORATORIES, City of New York. Dr. WILLIAM H. PARK, Director. Vol. VIII, 1914-1915.

THIS volume contains sixty-seven reports, of which twenty-three are not reprints. There are several extremely valuable reports having to do with diphtheria, Schick test and toxin, antitoxin activity, scarlet fever, poliomyelitis, and meningitis. Along lines of public hygiene are two good reports, one on public cigar cutters, and the other on the bubble fountain. Numerous other interests of the Bureau are indicated in the reports, and the volume is a great credit to the workers who are represented.

Society Reports.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Forty-Second Annual Meeting, Held at Indianapolis, Ind., October 10, 11, and 12, 1916.

THE PRESIDENT, DR. WILLARD J. STONE OF TOLEDO, OHIO, IN THE CHAIR.

Protozoic Enterocolitis in the Middle West.—Dr. FRANK SMITHIES of Chicago presented the records of the last 100 stool analyses in his clinic at the Augustana Hospital, which indicated that there were 93 instances where protozoa were observed. The patients' ages ranged from 7 years to 82 years. The average age was 39. There were 51 males and 42 females. There was practically no difference noted in the sex age figure. Fifty-two patients were of Scandinavian birth or extraction; the remainder were Americans, Germans, Irish, Russians, Austrians or English. The geographic diversity of patients forming this group was as follows: Illinois 29, Iowa 16, Wisconsin 13, Nebraska 8, Michigan 7, Minnesota 6, Indiana 4, South Dakota 2, Arkansas 2, Ohio 2, Texas 2, Kentucky 1, and North California 1. Of 93 cases 66 were large eaters of fresh garden truck, unwashed fresh raw fruits and bananas. Diarrhea was complained of in 86 cases. The duration of the diarrhea varied greatly. Sixty-seven per cent. of the cases had been affected from one to five years; eight cases had been ill less than one year, while a like number had been ailing for more than ten years, the longest period being 43 years. Constipation occurred in 4 cases. Dyspepsia was prominent in 75 cases. Abdominal pain or discomfort was a complaint in 89 cases. Loss of weight was noted in 75 cases. The loss varied from 5 pounds to 104 pounds. The average loss of 17.3 pounds. Loss of strength was often striking, even though the weight might have decreased comparatively little. Anemia was usually evident, although melancholia was frequently observed. On physical examination these patients generally appeared both starved and toxic. The stools were commonly of a greenish-brown or yellow color and of a puree-like consistency, intermixed with flakes of mucus and food bits. They might be blood-streaked or foamy. The reaction was usually definitely alkaline. In his series there were 40 cases with gastric achylia; 33 cases with subnormal hydrochloric acidity, and 20 cases with normal or increased gastric HCl. In one instance of most pronounced acute infection with cercomonads and trichomonads the free HCl was 86. The gastric motility was normal in 83 cases. In 10 cases there was mild stagnation. In 16 instances albuminuria was noted. His study of specimens of gall bladders and appendices removed at laparotomy indicated that in these parts of the gut cysts of protozoa might lurk for years. Reinfection of the bowel was thus possible.

Treatment of Infected Wounds.—Dr. FREDERICK G. DYAS of Chicago drew these conclusions: (1) The application of voluminous dressing to infected wound surface confines the infective discharges and subjects the tissues to a bath of pus. (2) Exposure of infected wound surfaces to the air causes a rapid drying up of the wound secretion and a desiccation of the tissues by the evaporating action of the atmospheric air, which can be increased by playing a current of air from an electric fan on the exposed area. (3) Infection from the air is negligible. (4) The open method of treatment tends to convert the moist into the dry type of gangrene and produces unfavorable conditions for the growth of anaerobic organisms which are clinically more virulent than aerobic. (5) The period of infection is shortened by the use of certain solutions, as a bath or irrigation, unfavorable to the growth of bacteria, which must be discontinued as soon as the signs of infection subside.

Dr. HENRY T. BYFORD of Chicago said the principle of drying out the wound was the proper one. To do that the wound must be drained, not the surface of the tissue Convert a wound into a dry, cancellous condition and it would get well. In treating wounds he began using the old-fashioned method of dry dressing, for bedsores or where there was a cancellous area which required some time to come off. He used gauze, but he did not have the same result as when he used absorbent cotton. When he began to use absorbent cotton in the proper way he would have a wound dry up in two or three days until finally it needed no dressing at all. But he changed the cotton every hour or two for a few times. After a few hours it would not have to be changed so often, say every three or four hours, then once a day, and then he would leave it on a week or until the slough came off. It was better to use cotton for this than gauze because gauze rubbed off the granulation. In fresh wounds that were not infected he would put on some cotton, change it in a few hours, and after that there would be less serum, and in a day or two the wound would dry up so that he would leave it, and it would heal up dry.

Dr. DANIEL N. EISENDRATH of Chicago said we must change our present method of treating infected wounds. The European War had shown that the battle which had raged between the upholders of the use of antiseptics and the upholders of the Wright theory had been decided in favor of the latter. If we stopped to think how infections were propagated in wounds, there were practically only three methods: (1) By continuity of tissue; (2) by way of the blood vessels, and (3) by way of the lymphatics, and the more he saw of infected wounds the more he was impressed with the fact that the third method was the most important one to combat. An infection by way of the blood vessels only took place in very virulent infection, and the other (by way of continuity of tissue) could be combated by means of the principles Dr. Dyas had laid down. In the lymphatic infection the microorganisms were carried into the lymphatics and from there into the systemic circulation. The principle upon which Dr. Dyas' method depended was first of all to have free drainage, so that there would be no possible absorption through the lymphatics; in other words, that the flow from the lymph vessels carried the organisms away from them instead of allowing the organisms to be sealed up in the wound or be forced into it. The method of treatment which Dr. Dyas had outlined, supplemented by these other practices, to induce constant lymphatic flow, was one of the most important things we had to deal with to-day in surgery.

Dr. F. KREISSL of Chicago stated that about forty years ago Hebra installed in a sanatorium for skin diseases a so-called permanent water bath for burns of the second or third degree and for wounds that did not seem to heal. This bath was arranged so that the water ran constantly at body temperature, the patient being suspended on a bed sheet so that he was not exposed to the pressure of the modern bath. The patients did very well; there was no bad odor, and nearly all of them got well. The same method was applied to the cold water treatment as it was originally introduced by Winternitz, and he supposed those gentlemen who had been in England and Austria had had occasion to observe both methods. These gentlemen advocated it in an empirical way, but the underlying principle was the same as expressed in Dr. Dyas' very able paper.

Dr. WALTER F. MCGAUGHEY of Greencastle, Ind., asked whether in the case of an injured hand the essayist would let a man go without any dressing on it?

Dr. DYAS replied that one man was walking around in the ward with a piece of ordinary window screen to keep the flies off. He had used wire screen very extensively in laparotomies and infected herniotomies.

Secretion of the Mammary Glands; Its Relationship to Albuminuria and Eclampsia.—Dr. W. E. GARY of Louisville drew these conclusions: (1) Eclampsia is a toxemia arising from the accumulation of material in the blood of the mother intended for the nourishment of the fetus in greater quantities than is used by the fetus and greater than can be eliminated by the maternal organism through the ordinary channels. (2) The greater the number of leucocytes in the blood of the mother the greater the toxemia within certain bounds, of course, due to individual maternal resistive ability. (3) The presence of leucocytes in the urine in large quantities is the first symptom of impending danger. (4) Leucocyte count of the blood of the mother may be reduced, albuminuria may be cleared up by the elimination of leucocytes through the secretion of the mammary gland. (5) When the convulsive stage is reached, damage has already been done to the kidney and other organs, so that treatment must be given to overcome this damage. This line of treatment is suggested: Inflate the glands to start secretion. Empty the uterus to get rid of the exciting cause. Eliminate by purgation. Support the kidney elimination by proctoclysis, as the patient cannot drink water. Control blood pressure with veratrum viride. By these

measures you can keep your patient alive until full elimination can be secured through the glands.

Ectopic Pregnancy, Diagnosis and Treatment.—Dr. Richard R. Smith of Grand Rapids, Mich., said the treatment of ectopic pregnancy was the removal of the offending tube with its contents and extravasated blood. This should be done as soon as suitable arrangements could be completed, but it was unnecessary to so hasten matters as to interfere with the operation being properly performed. In the city he preferred to remove patients to the hospital; in the country he preferred to go to them, rather than submit them to a railroad journey unless the case was one of long standing. During severe shock the patient might be removed to the hospital, and then it was merely a matter of judgment as to whether one should watch and wait for a better physical condition or operate at once. If, after say a few hours, the patient showed no improvement, he usually operated; if she did he usually waited six, twelve, twenty-four, or forty-eight hours. Under gas or ether anesthesia a median incision was made, a walling off and scooping out large clots of blood, and a prompt approach to the tubes. Great gentleness was attended with safety. The tube should be gently grasped and gently loosened if it was adherent. Roughness at this point might easily tear the tube from its attachments, and the patient lose further blood. The ovary might ordinarily be preserved, but in old standing cases with dense adhesions the ovary was apt to be so torn in getting the tube into the field that its removal with the tube seemed wiser. It was well to excise the tube well into the cornu of the uterus, as with an infected tube covering the denuded surface might be omitted in critical cases. Attention was then directed to the opposite tube. What should be done with it? If it was adherent, a gentle loosening from adherent structures was good surgery when time permitted. In young women or in those who had had few children, or desired more, the tube, if patulous, should invariably be saved. He thought it well to talk this matter over with the patient and her husband before operation. In older women and those who had already borne children and felt that they were through with child-bearing, it was wiser to remove it, for repeated pregnancies occurred in something like 10 or 15 per cent. of those women in whom a patulous tube was left at the first operation, and normal pregnancies occurred in less than half of those already operated upon for this disease. The removal of the appendix was usually unwise, but when matters were less pressing, and the condition of the patient seemed likely to give rise to future trouble, it might be removed. Usually the less we did in the abdomen of a woman with an ectopic pregnancy the better. The removal of most of the unattached blood clots was necessary, but the removal of partially organized and adherent blood should not be attempted. It was surprising how well everything cleared up after operation, far better than in inflammatory cases. No drainage should be instituted unless, as rarely happened, we were dealing with an infected case. The closing and suturing of the abdominal wall should be well done, since postoperative distention was perhaps more common than following an ordinary laparotomy.

Dr. William M. Harsha of Chicago said he would like to say a word or two about diagnosis. The essayist spoke of the pain usually not reaching throughout the extent of the abdomen. In some cases he had seen the pain had been very severe and very extensive, often reaching up to the sternum. The pain was of that type which had been called an abdominal crisis and it was out of all proportion to the lesion that we recognized as occurring in ectopic pregnancy. Here was a small tube no larger than a rye straw letting out a little blood, which was normal to the human tissue, and that little bit of blood just started a frantic pain. He had never been able to satisfy himself as to the cause of the great pain that occurred in tubular rupture, but the extension of the pain, if we assumed that there was bound to be pain from that little escape of blood, and the explanation of its general character, was to his mind found in the so-called overflow or reflex; for there was the abdominal brain, it was the herald of some great danger and the impression of that pain conveyed to the spinal column and from that point was reflected and overflowed into the adjacent segment, and so we got a pain all over the abdomen.

Dr. Daniel N. Eisendrath of Chicago stated there was one feature in connection with this paper he would like to emphasize, namely, those cases which we did not see at the time of rupture or within a few hours of that time. We were accustomed to see these cases of ectopic pregnancy either with extreme pallor or with moderate pallor. The cases to which he referred were those which we see after twenty-four or forty-eight hours, when the blood in the peritoneal cavity gave rise to symptoms of peritonitis, for the presence of a foreign protein in the peritoneal cavity would cause the same symptoms as a mild degree of peritonitis. We had the tympany, the rigidity, the tenderness on pressure and, above all, there was a very marked leukocytosis. He had seen several of these cases that he thought were typical cases of appendicitis, with a mild form of general peritonitis, but when we entered the abdominal cavity we found the extrauterine pregnancy had ruptured two or three days before.

Dr. J. H. Peak of Louisville, Ky., said that the time when this condition was first noticed was usually dependent upon what was occurring in the tube and how long pregnancy had existed in the tube. If the pregnancy had occurred near the extremity of the tube there was liability of a tubular abortion, and that might occur frequently without many symptoms and the patient might get well because extrusion took place. Operate then before there was much possibility of hemorrhage, and the patient would get well. If the pregnancy took place in the isthmus and further towards the uterus, when labor took place the hemorrhage would be more severe, and the more severe the hemorrhage the greater the amount of shock and tenderness and pain, and the quicker a diagnosis could be made. He had quite a number of specimens in his laboratory in Louisville showing the development in the various locations in ectopic pregnancy.

Is the Genealogy of the Gonococcus the Same as That of the Meningococcus?—Dr. Charles E. Barnett of Fort Wayne, Ind., drew the following conclusions: It is quite desirable to diagnose the meningococcus complication early, because the period of prognosis will be calculated for months rather than weeks. The treatment will also be dissimilar. There is no known method of differentiation except in the treatment of the case with its own manufactured antibodies (antimeningococcus serum), because it has been the writer's experience to have acute gonorrhea cases react to meningococcus vaccine. The laboratory findings for both the meningococcus and Neisser coccus are practically the same. The almost negative findings in the rectal examination and the rapid dilatation of the urethra and bladder following resolution would indicate the inflammatory action superficial rather than deep in the genital tract. Meningococcus infection of the genital tract is rare, or else only the most virulent ones are recognized. The overload of the kidney is quite manifest during the active stage of bacterial body elimination. The continued alkalinity of the urine presents a hazard that requires constant diligence in order to keep it within the bounds of neutrality. The meningococcus in the genital tract simulates the gonococcus in its action, precisely, with the exception of showing a marked increase in virulency and persistency.

Dr. E. O. Smith of Cincinnati stated that he did not catch from the reading of the paper what was probably the source of the meningococcic infection. As he understood, it was a gonococcic infection.

Dr. F. Kreissl of Chicago said that we all saw cases sometimes where the patient presented himself with an actue gonorrheal urethritis, and upon microscopical examination we found the patient had a typical gonococcus, and then when the acute condition subsided suddenly we found on microscopic examination that other microorganisms had appeared which resembled these very closely, and if we sent the specimens to a first-class laboratory man, what did we get? A mixed report. One day they would report to us a diplococcus resembling a gonococcus, Gram positive; the next day it would be Gram negative, and the next day a staphylococcus, and the Lord knows what. If we treated that case, after a time it seemed that the gonorrhea disappeared, and we would not find a trace of diplococcus or gonococcus, and yet the patient kept on having discharges. The patient was not usually prudent, and then all at once the discharge stopped, and then, without provocation, or perhaps with provocation, the discharge reappeared only to disappear with a few treatments. If we made a culture of these discharges we got practically the same answer. He had examined a great many cases carefully for years, and he

had never yet been able to get a report from the laboratory telling him there was a meningococcus, although all the others were fairly represented. No matter what we did for these cases we could not cure them, and he had come to the point where he told his patients their condition and that he did not promise them anything.

Dr. P. E. McCown of Indianapolis believed that in a good many instances from sexual abuses and some other causes we had a prostatitis arise, and following that from some excesses such as drinking the patient would have a urethral discharge. He had felt in a number of instances where men had claimed that they had not been exposed to infection that we were dealing with a staphylococcus, and he believed Dr. Wardle's work in Chicago had shown conclusively that staphylococcus could be a diplococcus many times. He also made the statement that it was more susceptible to leucocytes than the gonococcus itself. He had felt in dealing with these cases, and he had two at the present time, that we were dealing with a staphylococcus which was growing as a result of a prostatitis, there being a lowered resistance of the urinary tract which permitted the staphylococcus to grow. The staphylococcus was in intimate contact with the urethra at all times. We could perhaps get a staphylococcus growth there almost any time. These discharges were sometimes very annoying. Patients believed they had gonorrhea, and where there had been no exposure they could not understand the condition. In two instances these gentlemen accused their wives of infidelity, but after going into the matter thoroughly he had persuaded them that this was not the fact.

Dr. Barnett, in closing, said that Dr. Smith had asked for the source of the meningococcus. One could never tell the source. We might have a hematogenous infection most anywhere. In this case the source was from the girl, and yet the infection of the other thirteen men did not seem to be as virulent as this one. His idea was that, for instance, this was his first infection. This man, in fact, had had very little experience in sexual matters, and the epithelium was quite green, so in this case we had a greater virulence than where the field had been traumatized a good deal. He would say that it came from the girl. In regard to the prostatitis that Dr. McCown had spoken about, the first infection we got was *staphylococcus albus*, and then the whole bacillus, and finally the meningococcus.

Some Clinical Phases of Focal Infection with Especial Reference to Its Location in the Head and a Plea for More Accurate Classifications.—Dr. Joseph D. Heitger of Bedford, Ind., stated that a great field in the treatment of chronic focal infections lay before us, but the still greater field of prevention of a large percentage of these cases lay ahead of us. Childhood was the time to forestall and prevent many of these infections, and there was no knowing how much of the morbidity of later life might be prevented by proper attention to these foci in the head, especially the teeth, tonsils, sinuses and ears. In order that the profession at large might obtain the greatest good from these advances, there must be continual exchange of ideas, not only between the general practitioner and the specialist, but also between the different specialists. The saddest thing about some of these phases of focal infection was that men were classifying patients, putting them into this or that group, who were not studying these patients; who did not understand focal infection in its broadest sense, or at least they were attempting to put the focus where they wanted to place it and the patient learned by sad experience of the mistake in diagnosis. Focal infection, when found and properly diagnosed, offered much that bordered almost on the miraculous. Its treatment should be judged not by the worst that was done by some in falsely interpreting its hiding place, but rather by the best that resulted in those cases which were carefully and accurately diagnosed and classified. A routine method for their diagnosis and classification could be obtained and it was to this work that he would invite all to lend their best efforts.

The Surgical Management of Acute Perforation, Complicating Intraabdominal Infections.—Dr. W. D. Haines of Cincinnati stated that the type of operative procedure would depend upon many factors, chief among which would be the patient's general condition, *i. e.*, his ability to withstand operation. The length of time which had elapsed since perforation took place, the surroundings, the actual findings at operation and the experience of the operator were important factors for consideration in planning the operation. Many of these patients were in such a desperate condition when they were brought to the operating room that locating and closing the perforation and providing drainage as quickly and with as little disturbance to surrounding structures as was consistent with making a watertight joint and placing the drainage would best subserve the interests of the patient. Latterly the tendency on the part of the surgeon had been to liberate adhesions, resect damaged loops of intestines, provide drainage by anastomosis and remove all visible pathology and while ideal when the patient's condition and surroundings would permit of extensive operation, still by far the greater number of patients suffering from gastrointestinal perforation were in such physical condition as to preclude other than the least and quickest surgery which would reach the goal of closure and drainage at the primary operation, leaving the more extensive and technical elements for subsequent operation. A bad surgical risk before perforation took place, was not improved by the incident of perforation and a live patient with his perforation closed and peritoneal cavity drained, although the operation was incomplete, with much pathology in his abdomen, which might be removed later if occasion demanded, was preferable to turning the patient over to the undertaker after a technically perfect operation. Much good might be accomplished in the presence of extensive soiling of the peritoneum by gentle mopping with dry gauze, conversely much harm might be done by flushing the peritoneal sac. Perhaps the most that could be claimed by the followers of this all but obsolete and archaic practice of flushing the peritoneal cavity was that it insured the widest possible distribution of infectious material, destroyed newly formed plastic material and materially increased the mortality.

(*To be continued.*)

NEW YORK ACADEMY OF MEDICINE.

Anniversary Meeting, Held November 16, 1916.

The President, Dr. Walter B. James, in the Chair.

Dr. Walter B. James, in introducing the speaker of the evening, said that the Academy of Medicine had been founded in 1847 for the purpose of advancing the science and art of medicine in the city and the vicinity. Its halls frequently resounded to scientific discussion and to essays of highly technical character, but a very wise provision had been made whereby once every season someone outside the profession of medicine was asked to address them. There was a tendency in every profession to become narrow; one could often learn a great deal about his profession from those who claimed to know nothing about it. It had been said that after a man had reached the age of fifty years he was his own best physician. If that were true, and if it were true that a man grew better as he grew older, they had decided that Mr. Depew was good enough by this time to be accepted by the profession. He had gone away beyond the Scriptural three score and ten years and would tell how he had done it.

The Art of Growing Older, and the Value of an Interest in Public Life.—Mr. Chauncey M. Depew delivered this address in which he said, in part, he feared that if he revealed how often he had had to rely on a physician the old tradition about a man of fifty years being his own best physician would disappear. It was not often he confessed that he felt any trepidation in speaking in public, but he felt that it was dangerous to speak before such a highly specialized group of men. But if age meant experience, and no one could question but that a man past four score had had experience, then he was fitted to speak with authority unless there was some one older to gainsay him. It was true of all professions that their knowledge depended largely on experience (with the exception of the theologians) and that was the reason that they grew and changed and progressed. Seventy-five years ago, say when he was a boy seven and a half years old, his village had any number of old men and women. Every woman past fifty donned a cap which proclaimed her antiquity and wore a gray shawl, which advertised the poverty of her blood. Every man retired at seventy and lounged indolently about the house or sat on a nail keg in the village grocery store and discussed the events of the day. To-day one could not find a woman wearing a cap, and, indeed, it was difficult to distinguish the mother from her daughter. It was equally difficult to

find an elderly statesman on a nail keg, discussing politics. Modern inventions, the telephone, the cable, and easy and luxurious modes of travel had connected a far-spread world and did much to keep alive mental activity. Shakespeare, 350 years ago, applauded rapturously the seven ages of man. He died at the age of fifty-two, having given the world the greatest literature it had ever had, and at that time regarded himself as an old man. In his "Seven Ages of Man" he pictures the boy in the second age, with his satchel on his arm going whining to school. There was no such whining boy to-day; he was now either playing baseball or rooting for his side. In describing the sixth age of man, Shakespeare spoke of the old man as of "slippered pantaloon and shrunken hose" with his "shrill and piping voice"; to-day that man is at the bar—the legal bar, he meant—or in the pulpit giving to a listening world the best of his maturity. He spoke of the seventh age as "sans teeth, sans taste, sans eyes, sans everything"—now there was no such age, the dentist provided teeth, the oculist and optician provided better eyes very often than nature had given, and the housewife had better look out if the old gentleman found something on the table not equal to what he had been accustomed to in the old days. The ancients apologized for their age, and not only the ancients, but others. Cicero, at the age of sixty, wrote "De Senectute," in which he apologized at length for his old age. No one to-day would expect an apology from a man over eighty. To-day no one apologized for his age, but he was exceedingly proud of it. There were many ancient things of which one might well be proud. The oath of Hippocrates had never been improved upon and Hippocrates knew of many things that were still of value to the medical profession. Adam Smith of Edinburgh, the greatest political economist of his day, when an old man wrote the book entitled "Inquiry in the Nature and Causes of the Wealth of Nations." That book was responsible for England's policy of free trade and later for the adoption of a high protective tariff by America.

Mr. Depew declared that he knew of nothing which had had such a tremendous effect on the world as that utterance of David in the Ninetieth Psalm, "The days of our years are three score and ten, or even by reason of strength four score years, yet is their pride but labor and sorrow." No one knew how many untimely deaths this had occasioned. This had been proclaimed from the pulpit as an inspired saying and men and women died because they believed it. That psalm has caused more deaths than the war now raging in Europe. Dr. White, who formerly lectured in anatomy and physiology at Yale, said you could get any disease you wanted if you thought of it hard enough and long enough, and you could die when you wanted to. He spoke of having heard men say, "People in my family never live over seventy years," and they believed they could not live beyond that time. Dr. White said there was such a tradition in his family, so when he reached the age of seventy he decided to retire and to engage in a different occupation; he believed that in this way he could break the record, and he lived to be over four score. Some preachers believed and preached not only that man's allotted time was three score and ten years, but they believed and preached that if the time was extended to four score years it was as an actual punishment for sin. They took this view without taking into consideration the life and character of David. David grew up in poverty, became the leader of the army and then king of a small tribe. He gradually extended his power to the borders of Egypt. He had wealth and power and could enjoy every luxury that money could buy, and "he lived the life." When we take these facts into consideration in connection with his condition and attitude in old age we get a different point of view; the three score and ten years limit loses its power over us.

The speaker related that his great grandfather lived to the age of eighty, lamenting the decadence of his age, and bemoaning the fact that the end of the country was near and he was glad he would never live to see its downfall. The reason of this was because a Federalist (Jefferson) had been elected President. Jefferson had spent some time in Paris and was reported to have imbibed atheism, French culture, and radicalism. To turn to the other side of the picture, during his term as senator, Senator Hoar of Massachusetts, Senator Pettus of Alabama, and Senator Morgan of Alabama, all of them about eighty, were the leaders of the House, because of their wonderful grasp of all questions, their vast knowledge of history and their intellectual vigor and alertness in debate. Their longevity and their vigor of mind and body were due to the fact that they felt their responsibility to one hundred millions of people; they took very seriously their high office. It had been his good fortune to have been in Paris at the time that Michel Chevreuil celebrated the 102nd anniversary of his birth. He had entered the government service when eighteen years of age and had been promoted from time to time until he held a high position in the scientific world. He gave to France the dyeing process that assured to her the supremacy in the silk trade. His birthday was celebrated with great festivities. A gala performance was given at the opera at which he received a great ovation which he met with enthusiasm. He did not leave his box until two o'clock in the morning. The following morning he reviewed a large army of troops; in the afternoon he read a highly scientific paper, and in the evening attended a banquet at which Mr. Depew had the good fortune to be placed beside him. He asked Chevreuil how he had attained his one hundred years. The reply was that he had held a government position with regular salary and periodical increases, so that he had never had any financial worries; he had never used alcohol, but drank only the waters of the Seine (the Seine at that time was a sewer). While this conversation was going on an old man on the other side was filling his glass repeatedly and drinking to the health of every one. This occasioned Chevreuil much anxiety and Mr. Depew asked who the old gentleman was. Chevreuil replied, "that is my son." Mr. Depew asked how old the boy was and received the reply, "seventy-six." This child was the only real care Chevreuil ever had.

Mr. Depew stated that in his own experience and observation the fact that had impressed him most was the absolute control of mind over body. He felt quite sure that there was something in a man's mind which, if he could concentrate and control, would place him where nothing could ever happen to him. When a man lost control over his mind he lost his best asset for attaining longevity. To lose control of one's temper was absolutely destructive to the possibility of longevity, because this used up vitality. When a man carried his business always with him, to church, to the opera, to his home, it was fatiguing to him and he was making a great mistake. It was likewise a mistake to retire from business. The process here was always the same, unless one retired into another vocation in which he was as much interested as he had been in his business. The usual process was to retire to his old home town and settle down expecting to enjoy life with the same vigor that he did when he was a boy working in the village store. It went fairly well the first year; the second year he grew irritable; the third year he began taking medicine; the fourth year he took patent medicine, and fifth year one usually saw his obituary while those younger and better able were enjoying his estate. The question was, "What could man at this age turn to?" "Should it be sport or another occupation?" It was not always possible to engage in another occupation, but sport was always possible. Formerly elderly men turned to horses and took great pride and satisfaction in their paces. A man got a great deal of pleasure in seeing how much speed he could get out of his horses and in watching the superb play of muscles and nerve. This was invigorating and absorbing, but the automobile had destroyed this sport. After the automobile came golf, and now everyone was playing golf. Then there was billiards, but here there was the disadvantage that one must play at the club, and this meant smoking cigars and drinking a few cocktails. But a time came when a man could no longer even play golf or billiards and what was he to do then? There was always one field left and that was service; this would last to the end. There was service for one's country, for the State, for the municipality, for the church, for the hospital, everywhere. This was the one thing that would last for ever. Public life always provided an interest. Every man should be interested in government, for it was a personal matter, determining the conditions that governed his property and the amount of money that he could accumulate. If the methods of government were not what they should be this was the fault of the people. An interest in politics might be aroused just before a presidential election but it was then forgotten for the next four years. The primaries had been devised to overthrow the power of the "political boss," but the people took no interest in them, so the "boss" ran the primaries and he was now greater and more powerful than ever before because he had the sanction of the

people. There was no body of men better fitted to take a part in politics than the doctors, but they had failed in this matter of public service. All lawyers took an interest in politics because there were great prizes to be won, but not so the doctors; nevertheless there was no one of whom men were more afraid than they were of the doctors because of the confidential relation existing between the doctor and the families in which he practised. The doctor should bring the weight of his influence to bear at the caucus and at the primaries and all the way along to the polls. This, however, was not a subject for anyone to take up as a relief from professional duty. In government there were always with us the conservatives and the radicals, the Hamiltons and the Jeffersons, and just as long as one party was about equally balanced against the other we would not go over a precipice nor die of dry rot. Conditions today were parallel to those of the days of Hamilton and Jefferson; Hamilton stood for strong central government, Jefferson thought the central government should place the least restriction possible on the States. From the combination of these two views Washington produced the Constitution of the United States, the first constitution to survive for one hundred years. There was the same struggle between conservatives and radicals today, though perhaps Jefferson would be astonished at some of the things his party was doing. So long as there was this balance of power and people were interested the country would grow and prosper.

But, no doubt, someone was asking, "How about yourself?" For the benefit of that person he might relate that at one time, under the stress of affairs, he had reached a point where it became evident that he must have relief from the strain, and then he made the platform a way of escaping from busines and freshening up his mind. On one occasion he had had a very trying conference and went home completely exhausted. He had promised to make a speech in the evening. He lay down and rested, then prepared his speech, and appeared at a banquet at Delmonico's, where he delivered the speech in due form. He went home at twelve o'clock, slept well, and appeared at the appointed hour for further conference. Another man was there who said he had just seen a column in the newspaper about the speech Mr. Depew had delivered the night before and that he was destroying his reputation as a business man, for no one could see how he could attend to any business and have time left to prepare and deliver so many speeches. This man then told that he had played billiards, smoked, and drank a few cocktails the evening before and did not retire until two o'clock; he confessed that he did not feel good for anything. One must insist on regularity of habits, that a man get up early, and that he give up liquor and tobacco. There was no need for anybody being a mollycoddle or an insipid Pollyanna, but he should keep up an interest in all public questions, do his little charities and acts of kindness, not because he ought to but because he wanted to, and then he might go to eighty, to ninety, to one hundred years of age, feeling that it was a glorious thing to have lived in this beautiful life and to have enjoyed all that there was of it.

Role of the Endocrine Glands in Mental Disease.—Serradell in a recent thesis of Toulouse refers first to the psychic disturbances which accompany menstruation, and which are characterized by irritability, exultion, motor excitability, and also by indifference and apathy; while in certain cases true psychotic states are present. After ovariotomy women show apathy, irritability, sadness, weakening of memory, suicidal ideas, etc.; also psychoses of confusion or melancholia. The mental peculiarities and psychoses of the menopause are well known. But nearly all endocrine organs may play some part in mental troubles. In exophthalmic goiter maniacal states, melancholia and mental confusion have at times been seen. In acromegaly dementia, melancholia, and delirium of persecution may occur. In adrenal insufficiency the syndrome may include slowing up of the intellectual faculties, melancholia, and neurasthenia. Furthermore, in autopsies on the insane alterations of the endocrine glands are often apparent even although certain symptoms may have been absent. The good results of opotherapy on the insane represent further documents, the most striking having been noted in connection with psychic and somatic infantilism. The glands chiefly given are the thyroid, ovary, and adrenals.—*Journal de Médecine et de Chirurgie Pratiques.*

Therapeutic Hints.

Hydrotherapy as an Agent in the Treatment of Convalescents.—Radcliffe offers the various baths as a curative measure for those suffering from nervous disorders due to shock, or in cases of disordered action of the heart, giving defective circulation. In cases of frost-bite the running water bath improves the circulation, and the symptoms disappear after a few immersions. Sprains which present a sodden appearance, under this treatment, become filled with blood and reparation takes place. There are two types of baths—one for arm and one for leg. The running water is kept at a temperature of 105° to 115° F., depending on the susceptibility of the patient to heat. The arm, leg, or foot is placed in this bath for 35 minutes, then light massage and exercises are given. The pool bath for full immersion, in cases of heart and nerves, is given in a large tub with running water at a temperature of 92° F. Immersion lasts for an hour, after which the patient is made to rest. This bath must be given in a quiet room, softly lighted. The treatment usually lasts in all these cases from fourteen to twenty-eight days.—*British Medical Journal.*

Treatment of Tonsillitis.—Bush advocates absolute rest in bed even in light cases of this condition, particularly since the streptococcic type of tonsillitis seems to be gaining in ascendency, and is credited as the cause of certain types of rheumatism. Aside from the use of the salicylates, which is strongly advocated, alkaline or astringent treatment must be given the tonsils. The most rational treatment is the prompt preparation of an opsonic autoserum, and administration in proper doses, thereby affording nature a better opportunity for the production of those antibodies without which a cure is impossible. Antitoxins are nature's treatment for diseases and drugs are either accessories or mayhap impediments. It seems unnecessary to state that a brisk, but light purgative, such as Rochelle salts, should be given at the onset and low, nourishing diet maintained.—*New York Medical Journal.*

Nuts and Fruits in the Diet of Children.—Scott suggests the dietetic and nutritive value of these foods for children because they are palatable and enjoyed. The nutritive value of fruits is found in the salts they contain, and their therapeutic value in their laxative, diuretic, and antiscorbutic actions.—*New York State Journal of Medicine.*

Determination of Sex.—J. S. Freeborn gives a record of a series of 1,000 cases as a basis for his theory of determination of sex, in which a correct diagnosis was made in 97½ per cent. of the cases. Note is made of the occurrence of date of conception in the first or second half of the intermenstrual period. Conception occurred for females usually 5⅗ days after the last menstruation; for males, usually 19 days after the last normal menstruation. He is of the opinion that sex is fixed at time fertilization occurs; the ovum determining the sex independent of any inherent quality of the spermatozoon, and all ova maturing in the first of the intermenstrual period are female-producing ova and the later maturing ones are male-producing ova. Marital relations should be limited to the first ten days after the menses for girls, and to the last ten days of the intermenstrual period for boys.

COMMENTS UPON THE PERSONALITY, BEHAVIOR, AND CONDUCT OF CONVICTS IN SIBERIAN PRISONS, AS TAKEN FROM DOSTOEVSKY'S "HOUSE OF THE DEAD."

BY L. PIERCE CLARK, M.D.

NEW YORK.

MORE than a few workers in psychiatry have wished there were a psychological dictionary of human behavior and conduct, as a normal guide or standard to life reactions, by which they might, within relatively precise limits, judge the degree of variation of mentally abnormal and psychotic individuals. It is precisely the lack of this norm or pattern that brings out the innate defect of case reports in a just estimation of the actual beginning of psychotic reactions. Inasmuch as the new advance in psychiatry, as Hoch justly contends, must be made in gaining a scientific analysis and evaluation of ideational or delusional mechanisms, or mental symptoms of the older psychiatry, in any given psychosis, the need as above outlined becomes the more urgent. Had traditional psychology given us a good account of the emotions, we should not now find ourselves so destitute and in such great need for this aid.

In the absence of a normal psychology of the emotions, one turns to the careful analysis of personalities and characters made in neurotic and psychotic individuals in the newer studies on these subjects. But often enough these individuals have already shown exquisite or pronounced departures from the commonly accepted standards of individual and social conduct, so that almost any one may detect the glaring fault. The psychoanalytic movement in handling the neurotics and psychotics has demonstrated that the future of prevention in mental hygiene must rest largely in the early detection and correction, if possible, of the earliest abnormalities of these persons. Everywhere attention is being paid to the study of human behavior and conduct in the schools, juvenile courts, and in mental clinics. To analyze and give the excellent results already accomplished in this field would carry us too far away from the present purpose of this little essay.

It is not only desirable that the personality, behavior, conduct, and emotional reactions shown therein should be studied in the psychoses, and in so-called normal individuals, but we need equally careful studies on the interned criminals.

I venture to say that there are none so dull of comprehension that they may not find glaring faults in our prison administration, and that all will admit our approach to the problem of its correction must be based not upon a study of the prison inmates *en masse*, but upon an exact study of the individual criminal. Such studies should be made by trained criminologists in laboratories connected with the prisons, just as the insane are observed and studied in psychiatric institutions in our State hospitals. In search for some careful analyses of the personality of criminals, their behavior and conduct in the fine relief of a strict standard of discipline and accountability which close prison surveillance brings out, I came upon a description of the personalities, behavior, and conduct of convicts in Siberian prisons, as revealed in a critical study of Dostoevsky's "House of the Dead," recently translated. In this work I found many points of interest which I have judged of sufficient moment for review and comment.

It must be borne in mind that the prison buildings were dormitories only, and that all the men worked, either in the prison yard, or in the region surrounding the prison. Hence we find no mention of convict's pallor and certain other phenomena associated with prison life. Their faces were branded so they were marked men for life. It is not surprising to learn that prison life teaches the prisoners patience, yet, if one may judge correctly, but few profit from the instruction. We find that the effects of prison life are to age a man greatly, despite freedom from many causes of death and disease. The cause for this would seem to be largely or solely mental—the loss of hope being the greatest factor. The men in prison never fell asleep readily; as they lay thirty on a "bed" it would often take four hours before all were asleep. Therefore, a good night's rest was rarely experienced by any of the prisoners.

As already mentioned, the "branded face" was a constant reminder throughout life that they were outcasts. After the sentences expired they lived near the prison or in some other village as a "settler" and were for the most part considered "broken men."

It was noted that convicts seldom talked of their misdeeds or asked questions of others. It was considered bad form. Those convicts who bragged of hideous crimes were soon silenced, although not from indignation. It would seem to have been motivated from being bored than otherwise.

The chief personal qualities of the convicts were sullenness, envy, vanity, boastfulness, proneness to take offense, and great sticklers for form, all rather childlike traits. They never showed surprise at anything. The great majority were given to constant slander and backbiting. It was "good form" to submit to prison regulations and disciplines.

There was often a peculiar personal dignity about the convicts, although much of it seemed a bit stiff and overemphasized. There was never a sign of repentance or remorse; however, they seemed to

feel that they were there by their own fault, and have many sayings to that effect. But let one fully agree with them, and they often took offense, which makes one doubt their sincerity. When reproached or censured by a non-convict they cursed him terribly, as though the burdens they bore were quite enough without additions being assessed thereto. Often their behavior made one compare them to a lot of old women, so prevalent were backbiting, intrigue, slander, envy, and quarreling. Yet they instinctively respected a strong, dominating fellow prisoner.

They never by any chance brooded over their crimes. They even thought their behavior was ethical, which was no doubt in part due to extreme vanity. In other ways, too, they often exhibited a childlike naïveté.

It would seem that prison confinement and severe labor develop hatred, a lust for forbidden pleasures, and a "fearful levity"; the hatred always extends to society. After his punishment the convict feels purged of his crimes, and that in consequence he can begin again with a clean slate. Only in a prison does a man sometimes own up to most vicious crimes with a light heart.

As an instance of extreme repression of psychiatric interest is the fact that the prisoners almost universally form the habit of raving and talking in their sleep. They say, "we are a beaten lot; our guts have been knocked out, and that is why we shout at night."

Work as prisoners was hateful, but private work for which they received some compensation probably saved them from an increase of viciousness. It was shown here, as elsewhere, that a man must be able to work for himself and own property. This as a rule was not strictly forbidden in the Siberian prison, and there were cases, like that of a convict jeweler, in which a man's services were in demand by the villagers. They sometimes received alms when going to work. On long winter nights men worked with hidden tools, learned trades, etc. The chief proscription was in regard to owning tools. The graft system, in some respects, was like that in our own prisons, but no high officials took part in it.

Now that we have learned that the drug habit is either contracted or greatly augmented in all prisons, it is interesting to note that in Siberian prisons vodka was smuggled into the dormitories and sold, and some prisoners actually grew rich. But as money was of no value in prison—to the long-timers and lifers, at least—the money saved was nearly always spent in gambling, drunkenness, or on prostitutes. (This latter condition was rare, extremely expensive, and involved bribery; the usual substitutes were common.) Every man pilfered from every other man, and was usually thrashed for it.

The subject of a trade or calling pursued in prison, almost always in secret, was very diverse. Nearly every calling was represented, including money lending, teaching, valet work, trading, etc., etc.

Under the system of the prison in question there was much spare time in winter. The men thus thrown together were hopelessly bored. There is something peculiar and trying about life in common. The most energetic men are bound at last to "start something," a row, an intrigue, drinking, card playing—in which latter act a convict often lost his last shirt. About one-third of the convicts, however, worked at something, as already stated.

While real fighting was "bad form," men often "faked" fights for the entertainment of the others. They would insult, threaten, etc. But if they seemed about to fight in earnest they were pulled apart. Real fights are always reported by the guards, and an investigation follows. Swearing was not forbidden, and cursing matches were common. A connoisseur in cursing was respected.

A newcomer was viewed from various angles, one being in regard to the amount of money he might possess. They were anxious to get his money for personal service, tips about prison life, or by theft or fraud. Newcomers who looked like gentlemen were regarded with hostility and dislike. This persisted even after the gentlemen had become inured convicts. While the feeling of the peasant convicts toward the gentlemen convicts was a deep-seated hatred, some of it was from jealousy, as the latter had, as a rule, money, and could buy special privileges.

Convicts like piecework. They work hard until all is finished and they can then return to the prison and have time to themselves. As already stated, the convicts loved to have special work and own property. When this chance was cut off they grew depressed, and stopped at nothing to get money. It never stayed long with them, being either spent or stolen.

All convicts in the prison described seemed to be attached to a religious old man whom they called grandfather. He was free from disagreeable mannerisms, seemed childlike, bore everything bravely, was greatly cast down, but always strove to hide his melancholy, and would laugh in such a way as to compel liking. He was communicative, but never argued. In most ways he was the very opposite of the men in his special church. The convicts honored him by giving him their money to keep. "Grandfather," despite his simplicity, devised a most ingenious hiding place for it, where it was safe from theft.

It is unnecessary to state that a convict is eager for freedom. Yet money is seldom saved. When enough accumulates, his repression breaks forth in various ways. Some spend their savings in new clothing, usually of an assorted lot. Their pleasure in these clothes is quite childlike. They soon go to pawn, or are sold to others. If holidays were near at hand, the new clothes came handy. The clothes might be associated with a feast ending in a debauch. Very seldom indeed was any one asked to share it.

When a convict got drunk on vodka he was always shielded by his fellows—an example of communal action. All Russians, and especially convicts, have sympathy with a man who is helpless or irresponsible from drink. Although great precautions were always taken to prevent the report to the governor, usually the inferior custodians had no mind to interfere.

A talebearer, traitor, or spy among the convicts is never humiliated or shunned, and such a man even makes friends. The convict, as a rule, cannot be made to see anything wrong in treachery.

The prison reaction differs much with the prisoner and his crime. Some convicts enjoy prison life, become criminals in order to be imprisoned. Many find prison life no worse, or even better, than their outside existence. For the educated man, however, if he realizes what his life means, prison is a torture.

Convicts are not dangerous in the sense that they attack innocent people. All who come in business

contact with them fear their treachery; the convicts realize this fear and it makes them conceited. The keepers and higher officials must be firm and fearless to gain their respect, and must at the same time trust them. A high official who visits them unguarded is popular. Had any convict acted in a threatening manner, others would have suppressed him. Many wardens in our own prisons can testify to similar experiences. Nevertheless, one infers that the intense dread universally inspired by convicts must have some reason. Aside from their appearance, numbers, attitude toward society, etc., which give rise to theoretic insecurity, the narrator in the book of "The House of the Dead" knows of but one actual motive which is in evidence but rarely. The man who is to be flogged soon is in a state of fearful apprehension, and will do anything to "change his luck." Such a man may assault a keeper; it will, at most, cause an investigation which will defer the punishment for a short time. In the end the latter will be worse.

The convict has an extraordinary love for physicians, who can sometimes prevent floggings for the time, although he knows that punishment is coming to him as soon as he leaves the hospital.

Any convict, however sturdy, will put off a flogging. The ordeal seems to be too severe for them to want it over at once. Some proud ones try to seem unconcerned before the act, but they deceive no one. The convicts show humane impulses by their failure to make comments on such men.

When the convicts are locked up in their sleeping room with no keepers present, conditions become "homelike." The lights supposed to be doused were at once relighted, for each man had a candle and stick. The workers took up their private labors already mentioned and others played cards. At times card playing never ceased until the doors were unlocked in the morning and never until the great majority were broke.

As regards class spirit in prison, it was shown there was a special type, down and out, and devoid of pride or initiative who were content to wait on the others, run errands, act as sentinels, etc. For a few kopecks a night one will act as outside sentinel and nearly freeze. The free-hearted convict, possessed with money and filled with vodka, is never generous with these fellows, and always beats them down to the lowest figure and insists that they carry out their agreement faithfully.

A convict is sometimes tricked into "changing names" while en route. By impersonating another convict he is sure to have much the worst of it, while the other gets a lighter sentence. The price paid is usually ridiculously small. Such victims always remain objects of derision, which is chiefly because they did not hold out for a large sum of money.

Toadying and spying have been mentioned before. Some of these men were actually admired because of their art in getting around the superintendent and often deceiving him to their own advantage.

A convict without one kopeck in his pocket was tenfold more dejected than one who had a few of them. Had the chance to work for themselves and the possibility of private gains been eliminated, these men would either have gone mad, pined away, or committed some outrage for which death would have been the penalty. No class of men is so greedy for money, none spend it so rapidly or foolishly. To possess it they cheat and rob one another; they will do anything whatever. Yet despite their passion for freedom, they never save up against it, for to be able to spend money, to buy vodka, to meet with women makes him feel that he is of some account for a time even in prison. This harmonizes with the fact that convicts have a tendency to assert their individuality by bragging, bullying, etc., and money alone can make this attitude real.

Of great interest are the occasional instances of running amuck, so to speak, in men who have been model prisoners for years. Their behavior is demoniacal, and they may commit murder or rape; they get drunk and disorderly, play pranks, etc. Their "crushed personality" rises and asserts itself until it reaches a pitch of fury, spite, mental aberration, or fits and convulsions, quite terrible to contemplate.

Every expression of personality on the part of a convict is repressed as criminal by the authorities. Dostoevsky calls the explosions or reaction engendered by continual suppression of his individualistic desires poignant hysterical cravings for self expression. He believes that a man buried alive might act in the same irrational manner when he realized his condition.

Convicts either show scowling brows or overjubilant faces. Volunteer entertainers, buffoons, etc., while they may at times divert the convicts, are despised and abused. This seems to be due to their lack of repose and self control. In a word, it is "bad form," for the convicts wish to be stoical, reserved, and dignified. Occasionally they tolerated this sort of man if he would strike back at them.

Convicts look down on peasants, although half of them are from the peasant class.

When set to a task, convicts are unable to agree among themselves as to how it should be performed. An outside foreman seems necessary. Once they have received their orders, they work with surprising energy, such as breaking up an old barge and saving what was worth while. This speed was due, perhaps, to the piecework concerned. But by working with speed they saved a half hour a day, though they worked very hard.

The prisoner's first dream on entering a prison is always freedom. Hope would seem to be a much stronger feeling in a convict than in a free man. He has an unconquerable feeling that he is merely "on a visit" and must some time return home. When he first enters there is apparently no difference between a two-year and a twenty-year sentence. He pictures himself released with all the qualities of youth unchanged. Even after a long sentence life is still before him.

If a man is fond of ordinary prison labor (perhaps only because the exercise is good for him), the convicts gibe him. Shoveling snow was agreeable to the convicts and they worked in gangs in order to quickly release buildings snowed in. Nearly all became cheerful. Snowballing was frowned on as undignified.

It is interesting to note that convicts perhaps unconsciously demand some respect from others and wish humane treatment. Food and shelter are not enough. Good men with kind words can do much with them. But the convict does not wish his officials to be soft, for then they could not respect them. They have some pride in their governor and wish him to be dignified, with decorations which point to past honors. They like it if he has a "pull." From him they demand strictness with justice.

One man of the "comedian" type whom the convicts call both "foolish and useless," had no use for

the men who despised laughter and because of this resentment was treated with respect.

The convicts appear to have been religious throughout, crossing themselves, praying to ikons, etc., and at Christmas denied themselves in various ways, by avoiding swearing, etc. While in general decidedly unfriendly to one another, on Christmas they at least tried to be friendly, giving Christmas greetings to those whom they had always disliked.

The intense delight of the convicts in the private theatricals given during Christmas week was, of course, natural, relieving the prison monotony. Nearly all wished to help in some way and only the best men were in demand. Even the author, as an educated man, was for once treated with respect by his enemies. Outside the prison some bluffer might have secured prestige but in prison the convicts are not deceived. Under these conditions justice becomes a virtue. The best man for the place will have it whether or not they are on good terms with him. The author comments that no wise man can teach these convicts, but often could learn from them.

At the Christmas entertainment there were not enough seats for the convicts, but there was no scramble. It would have been very bad form to have behaved badly on such an occasion.

The audience at the entertainment was carried away; their faces softened and even seemed childlike. Applause was generous. The music and acting seem to have been superior. The play was one which dealt with a knavish servant, and his pranks were wildly applauded. The convicts were proud that they could turn out such an entertainment.

It seems that the convicts never tired of praising the doctors. They often compared them to fathers.

Some patients in the hospitals were really ill; others were sent by the doctors "to have a rest." If there were plenty of spare beds the doctors filled them with patients who while not really ill were deserving of sympathy.

Some patients were suffering from the effects of flogging. Their reception by the inmates depended on the offense for which punishment was given as well as the extent of the latter. A very bad man who had been beaten hard enjoyed more sympathy than a runaway recruit. No comments of any kind were made. Orderlies' services were not required. The convicts who were able took full charge of the beaten man and better care he could not have had. The author gave one such man a cup of tea. He was too dazed to thank him. After having done all they could the convicts at once ceased to notice him.

The doctors treated every man with kindness and spoke friendly words to all. The convicts knew the physicians were not obliged to do this, and therefore appreciated it. They would not have minded rough treatment. Therefore the doctors were strictly on the level.

It is surprising to learn that no convict, however sick, ever had his fetters removed, they died in them. Even the doctors did not interfere. The weight was ten pounds and they were so little in the way that they did not interfere with escapes. On the other hand, in wasting diseases they became a burden. The author came to regard them as a mere badge of degradation.

The "ward doctor" was so kind as to be looked on as "soft." He could be imposed upon, was also diffident, blushed easily, etc.

A number of the men who rested up were untried prisoners—detained in unsanitary quarters. These men were really much worse off than convicts; as a rule they were pale, thin, and weak. They had no disease, but the sympathetic doctor gave them some imaginary affection, and did not have the heart to mark them "cured" after a long rest. The head physician, however, was just and much respected because he would not stand for malingering.

The men bore no vindictiveness for their beatings, but would goodnaturedly discuss them, the number of them, those who did the beating. The men seemed to realize that, having broken laws, they should be punished. They showed much fatalism here as elsewhere.

It is rather surprising to learn that some floggers compel a certain affection. They do not play tricks, such as pretending to let them off and then suddenly flog them. The popular kind, while they flog hard, speak a kind word, or otherwise inspire a friendly feeling. The man referred to after he left the prison was always remembered as a "jolly good fellow," a "father to us."

Time in the prison hospital was passed in telling stories, looking forward to the doctors' visits, and in eating. Individual feeding was the custom, and the man with scurvy fared best of all—beef with onions or horseradish, vodka now and then. The special diets did not please all and trading rations was common. Some had no desire for food and gave their ration to a neighbor.

Nothing pleased the convicts so much as the admission of an insane man, but the latter soon got on their nerves. Insane recruits had to stay there until other quarters could be secured. Straight jackets were applied but did not help much.

Convicts who were not very ill disliked medicine, and at times would not take it. But a very sick convict liked to be fussed over—bled, cupped, poulticed, etc. Some found cupping painful—men who had lived through the worst beatings.

"Candle light" was the worst time of the day for the prisoners. It is a time for thinking, dreaming, reminiscences, and speculations as to the future, such as what will one do when his time is up.

We note that spring has a peculiar effect upon the convicts. It arouses desires, cravings and a yearning melancholy. They are impatient and restless and more apt to quarrel. There is more noise and shouting at this time of the year.

To "change one's luck" is a characteristic expression. The convicts, despite the impracticability of getting out before their time is up, always have hopes that luck will change. This wish seems to concern only the prison that he is actually in. He might possibly be transferred to another one, and there are other hazy possibilities.

The convicts took the sacrament once a year and had a week to prepare for it. No work was done, and they went to church two or three times a week. They attended a church in the town, but were not allowed to pass beyond the background. The convicts prayed devoutly, put in their penny in the collection. Reference to the thief on the cross was looked upon as personal, and all kneeled in a body at this moment.

When the convicts had time some one subject usually came up for general discussion. These were often rumors. However improbable these were, the convicts showed all the credulity of children—even when the rumor came through a notorious liar.

One of these rumors actually came true. It referred to a tour of inspection by a high official.

Convicts delight in discussing officials, rank and precedence, and who has the most power when a quarrel comes. They almost quarrel in these arguments, one saying a certain general is superior to another. These discussions are regarded as more refined than any others.

There was a regular prison horse and when it died another would have to be supplied. The convicts took the greatest interest in picking the successor. They seemed to be buying him for themselves, and were as delighted as children. A large proportion of the men were "horse jockeys," many lived on horseback when free. Some wonderful "judging" was seen.

The convicts in general were zoöphiles, although for some reason they disliked dogs, regarding them as filthy brutes. They utterly ignored them (this is the peasant idea of dogs). Pets were not allowed, but at different times there were goats, geese, etc., beside the prison horse. Most remarkable was a wounded eagle who would not make friends. When finally they let him go, they sympathized with him. He had never shown the least friendliness. For awhile he was forgotten in the prison ward but someone always fed him.

Convicts, especially lifers, including the most sensible among them, led a strange inward life, a sort of dream existence accompanied outwardly by restlessness. The peculiar facial expression of most convicts, gloomy, sullen, unnatural, was also an index of this dream life. At times the dream was almost a delirium. An illogical sense of hope was part of the mental state. There was also the almost delusion that they were only on a visit, after all. Such men must necessarily dream. Such psychic life is seen outside of prisons only in the psychoses and psychoneuroses.

Convicts always regarded candid, simple, honest people as the worst of fools. The ill-humor, the vanity of the convict would make him antagonistic to such opposite types. The few really good-natured people among the convicts had to dissemble. Sometimes a very religious man got comfort from feeling that he was a martyr.

There was once a complaint by the convicts about the poor quality of the food. A committee waited on the superintendent. The "gentlemen" convicts held aloof. After the strike had ended disastrously, the beaten convicts made no reproaches to the "gentlemen." Neither did any of them take any action against the agitation. The whole matter was definitely dropped.

The convicts actually loved one of the superintendents, although he did not remain long. They spoke of him as their father. He seldom passed a convict without a kind word or humorous remark. He did nothing to bring about want of respect. He was a small, cocky kind of person, looked very dissipated, had no air either of authority or patronage. The convicts actually smiled when he addressed them. He looked absolutely fearless and self-confident.

When a convict actually escaped the men were tremendously excited. Prison monotony vanished. All were joyful. These escaped men had actually "changed their luck." The convicts began to swagger in the presence of the guards. In the interim the escaped convicts were discussed fully. But in a few days they were brought back. The convicts then became angry and depressed and abused the men because they were taken. From then on they had no use for the losers, and ignored them.

Something of humanizing value has been obtained in the reform of the Russian exile system, if various reports are to be believed. Unfortunately, however, the treatment of the criminal class has not been as sharply demarkated from that administered to political offenders as one might wish, as yet. Much of the punitive, instead of the reforming and constructive upbuilding of personal character still obtains.

The modern view of reform treatment in our States' prisons has been on trial among us for several years. It remains to be seen if it is not too late to bring about a great moral regeneration in the confirmed criminal, one in whom the anti-social attitude is so definitely formed that new habits of proper adaptation cannot be instituted. However this may be, I think that most psychiatrists are anxious to see what some real studies in this direction will produce. Undoubtedly a broad and comprehensive study of the various types of criminal behavior and attitude from the first apprehension and infringement against the law and social order to that of final incarceration of the old offender in our States' prisons, will be very useful in determining the correction of much of the new attitude in prison reform and point the way even more closely to sane and safe methods conducive to future progress.

If one were to propose a scientific method of approach to the whole problem it might be formulated as follows:

There should be centers for study of the anti-social or criminal tendencies in the confirmed group as in our States' prisons, in the less severe grades of criminal acts as in our male and female reformatories and in the mildest or most benign offenders as in the juvenile courts and first offenders. Then if these careful case-history studies and the environmental influences in which the criminal acts had their origin could all be assembled for group and mass analysis we might have a fairly comprehensive understanding of just what types of inherent traits in different individuals are likely to be benign and what are malignant. It would then be possible to formulate a diagnostic and prognostic attitude toward the whole problem of criminality, one of the most pressing issues that confronts society to-day.

This hastily sketched scheme would probably require at least several autonomous research groups of workers over a period of several years' study. From time to time, general conferences between the different groups of workers could be held and thus find where their individual studies dovetail together, and also find where they could help each other on methods and material studied. Research of this character would require the very best trained men and would probably be rather costly. It is obvious that from the very nature of the study it should be done under private grant of funds.

Since the foregoing article was written, the Rockefeller Foundation has seen fit to aid in establishing a psychiatric clinic at Sing Sing Prison. The same agency has already undertaken similar research work at the Bedford Reformatory for Women. Both efforts give promise that we may soon be in possession of actual clinical data which will be of the highest value in shaping a more enlightened policy in the care and training treatment of criminals.

128 East Sixty-first Street.

REMARKS ON ANTERIOR POLIOMYELITIS.

WITH REFERENCE TO THE PRINCIPLES OF TREATMENT AND THEIR PRACTICAL APPLICATION.*

By ROYAL WHITMAN, M.D.,

NEW YORK.

THE present epidemic of anterior poliomyelitis has been so thoroughly exploited in the newspapers that it may be the general impression that the disease is a new one, that its characteristics are not well understood, and that novel remedies are now to be employed in its treatment. As a matter of fact, it differs from the epidemic of 1907 only in the greater number of cases, in the higher death rate, and in the larger proportion of complete recoveries.

What is actually new is the general interest that has been aroused in the subject, which will assure better opportunities for the scientific study of the disease that may eventually lead to its prevention, and which will certainly assure more efficient treatment of its effects than in the past. It is with this latter phase of the subject that we are at present concerned, and the most practical development toward efficiency is, it seems to me, the enlistment of the social-service workers; since they will have the opportunity to inspect the conditions of the homes, to send neglected cases to hospitals or to day nurseries, to instruct the parents as to the character of the disability, and to supervise the practical application of the treatment.

This is of the greatest importance for, as has been suggested, the present epidemic has brought out as yet no novelty, and the hope for the future lies in the more efficient and general application of methods which have been tested in the past. Under efficient treatment, by far the larger number of the patients may become, eventually, useful members of society, and the contrast in the final results between the patients who have received such treatment, and those who have been neglected is convincing proof of its value.

Anterior poliomyelitis is an acute infectious disease which involves the central nervous apparatus, and paralysis and deformity are its consequences.

During the early stages of the disease the paralysis is usually widespread, because many centers and conducting tracts are temporarily disabled by congestion and swelling. Others are damaged in a greater or lesser degree, and others are destroyed. At this time, therefore, it is impossible to predict what the area of permanent paralysis is to be. When the acute stage has passed, repair begins and proceeds rapidly at first, indicating that the congestion has subsided, and that motor impulses are again transmitted, and in possibly 20 per cent. of the cases this may go on to complete recovery. In the majority, however, the response in many of the muscles is feeble or absent, indicating that the centers that control them are severely damaged and that the process of repair will be long delayed.

What is called orthopedic treatment consists primarily in keeping the machinery in condition to take up its work, if repair of the nerve centers permits, and to adapt by some means the disabled members to the needs of the individual. In this treatment the prevention of deformity is of the first importance, because deformity throws the machinery out of gear so that it is unable to respond to the impulses that may be transmitted to it. From past experience it may be stated that by far the larger number of patients in all classes of society become deformed to a greater or lesser degree, and therefore unnecessarily disabled, deformity being the inevitable consequence of the disease unless it is prevented.

The causes of deformity may be classified as: (1) The force of gravity. (2) Persistent attitudes. (3) Unbalanced muscular action. (4) Weight bearing and locomotion.

1. The influence of the force of gravity is best illustrated by the hanging downward of a paralyzed foot when the patient is sitting or recumbent. After a time the habitual attitude becomes fixed by contraction. Thus the hanging foot or what is called equinus, is the most common of deformities.

2. Certain attitudes are often induced by discomfort, or they may be simply accommodative, as the sitting posture, in which the limbs are bent at the hips and knees. Thus flexion contraction at these joints is very common among patients who are unable to stand.

3. The muscles in health vary in strength according to their function, and are arranged to support and balance one another. The calf muscle, for instance, is large and strong, because it lifts and propels the body, while the smaller muscles balance the foot. Paralysis of the calf muscle causes great disability with but little immediate tendency to distortion, because it is opposed by the force of gravity; while paralysis of lateral muscles of comparatively slight importance will induce deformity, because the foot is drawn to one side by those of the opposite group.

4. Locomotion and weight bearing upon a weak and unbalanced extremity exaggerate existing deformity, and increase the resistance to correction. Deformity develops, therefore, more rapidly and to a more extreme degree in early childhood than in later years.

Prevention of deformity is the most important part of the treatment from first to last, since if it is present, it is impossible for normal muscles to act effectively, and for weak muscles to respond to impulses and to regain their strength. It develops insidiously and far more rapidly than is generally believed. More rapidly in the partly paralyzed cases than in those of complete paralysis, because the influences of the force of gravity and accommodative posture are increased by unopposed muscular action and by retraction of active muscles that are never as in health stretched to their normal limit.

The first indication of deformity is the evidence of discomfort when an habitual attitude is changed. When, for example, a hanging foot is pushed upward. And, in cases in which the muscles of the front of the leg are paralyzed and the calf muscles are active, this discomfort is often apparent within a few days of the paralysis. In fact, much of the pain supposed to be symptomatic of the disease is actually induced by tension on contracted tissues.

Preventive treatment consists in moving the joints of the affected part through their full range of motion at least twice daily in order that all the muscles may be extended to the normal limit. Postures should be alternated, and attitudes that lead to deformity should be restrained. If, for example, the trunk muscles are so weak that the body is bent forward or to one side in the sitting posture, the child should not be permitted to sit unless it is properly supported, nor to stand or walk on weak and uncontrolled limbs.

*Read before the New York Conference on Hospital Social Service at the Academy of Medicine, November 1, 1916.

The secondary part of the treatment is directed to the preservation of nutrition of the paralyzed parts. Nutrition depends upon the circulation of the blood, and the supply of blood is regulated by the work performed by the muscles. Paralyzed muscles do not work, consequently, they receive less blood. Paralyzed limbs become, therefore eventually shrunken, cold, and discolored; the capacity of the blood-vessels having been lessened because no demand has been made upon them. These changes are far more noticeable in deformed and unused limbs than in those which, although equally disabled, have by treatment been forced to carry out as far as may be their normal functions.

Massage.—Nutrition may be improved and in some degree preserved by local treatment. That which is usually applied is rubbing and friction, under which warmth and color may be restored to the paralyzed part. Parents do not understand the objects of so-called massage, but look upon it as a direct treatment of the disease, and what they rub in is of greater importance than the rubbing. Oily substances are supposed to feed the weak tissues; actually they only serve to lessen friction, which in these cases is desirable since only gentle rubbing should be permitted.

Baths.—Baths, to which in health parents are unaccustomed, are thought to possess mysterious virtues, and this belief may be encouraged. A warm bath in which the child may lie extended stimulates the circulation and assures the most favorable opportunity to demonstrate muscular activity in the floating limbs, because it is not opposed by friction and gravity.

Electricity.—The most impressive of all remedial agents is electricity, because the paralyzed muscles may, for a time, respond to its stimulation. It has been employed for many years in the treatment of all forms of paralysis, but no positive evidence has been presented that it has any effect other than as a local stimulant of nutrition. It is far better adapted to the treatment of older patients than of young children, who are usually frightened by even the slight discomfort attending its application.

Muscle Training.—The treatment that is in the air at present is muscle training. Just as strong muscles may be made stronger by systematic exercise, so weak muscles may be made stronger by exercises adapted to their weakness. This is, of course, self evident. There are very decided limitations to the method. Paralyzed muscles cannot be trained, and young children are usually poor subjects either for muscle training or muscle testing. The treatment is of great value in suitable cases. If properly applied it should lessen the tendency to deformity and aid the restoration of power in muscles in which such restoration is possible. If all the muscles are equally weak any improvement in strength is so much gain, particularly in an upper extremity. If, on the other hand, the weak muscles are capable of recovering but a fraction of their strength in opposition to the full power of an opposing group, deformity cannot be prevented in a weight-bearing extremity, except by mechanical or operative treatment.

Braces.—Braces are used to prevent deformity and to permit locomotion. If the paralysis is general of the trunk and limbs, the child may be placed on a recumbent frame, on which it may be carried about, because if permitted to sit, deformities of the trunk would develop, which are progressive and intractable. Or, as a temporary treatment, a plaster support may be applied, which, by fixing the spine, assures the rest that favors the repair of the inflamed spinal cord, and holds the uncontrolled and often sensitive limbs in proper position. Plaster supports are of value, also, as temporary braces during the early stages of the disease, before the extent of the persistent paralysis can be determined.

The chief value of braces is as aids in locomotion; for as soon as the discomfort has subsided a child will insist on moving about, if this is possible. Braces are employed to protect the weak muscles and to lessen the strain upon the joints which would otherwise induce deformity.

Functional Use.—Functional use, if properly regulated, is the most powerful of all the stimulants toward recovery, as contrasted with purely local treatment. For the muscles and the nerve centers are interdependent and if a limb is permitted to become deformed and shrunken from disuse, the nerve centers, although capable of transmitting impulses, may atrophy for want of practice, while those upon which constant demands are made should develop their capacity to the highest degree. Functional use is often impossible without support, and the character of this support is, therefore, of greatest importance in treatment, since it must be often changed in adaptation to the needs of the patient.

Prognosis.—It has been stated that it is impossible to predict the degree of final paralysis in any case, since improvement may continue for many years. There are, however, certain very definite indications on which to base the prognosis. In favorable cases there is evidence of returning power in certain muscles throughout the paralyzed limb, indicating repair through a corresponding area of the cord. The instances of practical recovery after many years of helplessness are cases of this type, in which restoration of function has been prevented by deformity, although the nerve centers have been repaired. The unfavorable cases are those in which, in spite of protection, certain groups of muscles in a definite area show no sign of power, while in other parts recovery has been partial or complete.

Operative Treatment.—When the area of permanent paralysis can be accurately determined, usually after an interval of several years from the onset of the disease, operative treatment may be indicated, and this is, from the positive standpoint, the most effective of all remedies. It consists essentially in transferring active muscles from their original insertions to points where they may work to best advantage, and thus to restore the muscular balance; and in operations on the bones and joints to assure stability, so that braces may be less burdensome or discarded altogether.

Having reviewed the principles of treatment, one may now consider their practical application.

It may be a general impression that the solution of the problem is hospital care, but this is as undesirable as it is impracticable, since we are dealing with a disability of indefinite duration, and not with a disease that will run its course in a few weeks. In many instances the disability is slight and even in the cases that might be benefited by hospital care the consent of the parents cannot be readily obtained, since no definite statement as to the time of separation, or the outcome of the treatment can be made. A large proportion of the patients are so young that they need a mother's care, and in the majority of cases home treatment is to

be preferred. We may conclude, therefore, that treatment must be adapted to patients of what is called the ambulatory class.*

In the present stage of enthusiasm, I am inclined to think that there is more danger of over treatment than of neglect, and that as far as young children are concerned, the possible benefits of massage, electricity, and muscle training in a crowded clinic are more than offset by exposure, fatigue, and excitement, not to mention the time consumed by the mother.

The clinic should be the central point for observation, supervision, and teaching, while the mother, properly instructed and aided, if necessary by the visiting nurses, must be depended upon to carry out the supplementary treatment. Muscle training, for example, however difficult in its adaptation to many patients, is very simple in its application to a single case; although it requires art, patience, time, and opportunity, qualities and conditions hardly available in a large clinic.

In conclusion, it seems to me that the contributions of those who are interested in this subject may be used to best advantage by increasing the facilities of the hospitals and clinics already equipped for the work, and by providing a larger number of social workers and visiting nurses, with adequate means of transportation, all under central control, than by establishing new clinics in more convenient localities, on the supposition that daily treatment is essential. In other words, that the best results from the educational, scientific and humanitarian standpoints may be obtained by a concentration, rather than by a diffusion of energy.

283 Lexington Avenue.

SOME ASPECTS OF THE TREATMENT OF INFANTILE PARALYSIS.†

By HAROLD W. WRIGHT, M.D.,

SAN FRANCISCO.

The general principles regarding the treatment of the effects of anterior poliomyelitis are now quite generally understood and agreed upon; but the practical application of these is often neglected and the little details of treatment which count for so much are many times overlooked or but vaguely comprehended by both general practitioner and orthopedic surgeon. Were conditions otherwise we would not see so many preventable deformities in the clinics nor so many badly functionating limbs in faulty apparatus. However, another explanation of the large number of deformities seen on the streets of cities and in rural districts may be the still prevalent attitude of the laity and also of many general practitioners toward the treatment of crippling diseases, an attitude characterized by passive pessimism. Anyone who has worked in orthopedic dispensaries can recall numerous instances of preventable deformity in which the patients had been told that nothing could be done for them when most could have been done toward preventing deformity and thus ultimately securing good function.

Treatment of the Acute Stage.—Have we any therapy at hand which is in any way efficacious for preventing the extension of the acute process in the spinal cord or for hastening the resolution of this inflammation?

No statistics are available to decide this point. We can only speculate about it. Theoretically we can apply the ordinary principles of counter-irritation, elimination, and supportive treatment to the initial stage of poliomyelitis; these principles embrace such measures as cupping the spine, catharsis, diuresis and diaphoresis, and special attention to the proper nutrition of the little patient. Unfortunately, the disease does its damage so quickly and without premonition that these measures can avail little in most cases. There is one other principle which we are accustomed to apply to the subacute stage of this disorder which is even more in order during the acute phase; namely, efforts to secure complete rest of the voluntary and reflex mechanism of the motor part of the central nervous system. This principle of rest is a cardinal one in the treatment of inflammation in any part of the body; that it is not more definitely applied to cases of poliomyelitis is because of the inaccessibility of the parts involved. However, it would seem rational to attempt to cut off as much as we safely can do the afferent and efferent stimuli to the anterior horn-cells and to do this we might make more use than is generally done of plaster of Paris as a means of immobilizing the entire body during the very acute stage, *i.e.* for the first week, in order to lessen the irritation of the nerve-cell protoplasm which is already in an abnormal condition. Other measures directed to the same end would be the administration of chloral and bromides in sufficient dosage to keep the patient quiescent. The body should be well padded and the limbs placed so as to prevent the stretching of any muscle, *i. e.* placed in balance, before the plaster bandages harden.

We do not know how long the inflammatory reaction in the spinal cord is of an acute character, nor how long it will be before the tissues of the cord become normal or as normal as they ever will be. We need more data upon this aspect of the pathology. We therefore need to be conservative in discontinuing the measures which enforce complete rest of the central nervous system; certainly they should be carried out for the first ten days or two weeks, no matter how small an area of the cord we may presume to be involved, for all parts of the nervous system are very intimately connected.

Lumbar puncture is worth while in the beginning of the disease, especially if there are any meningeal symptoms;it may relieve congestion and certainly can do no harm.

The Subacute Stage.—After the first ten days or two weeks the therapy of this disease ceases to be a medical problem and becomes primarily an orthopedic problem. We can now estimate the amount of damage done to the cord and the nature of the mechanical defects to be remedied. Our efforts should be directed first of all and all the time to the preventing of the stretching of weakened muscles either by gravity or the pull of their antagonists, *i. e.* the maintaining of all muscle forces in equilibrium. This can be done by plaster splints most readily and efficiently during the first few weeks of the subacute stage; the foot and leg should be held in the position most favorable for later standing

*The Social Service Workers have analyzed for me 200 consecutive cases treated at the Hospital for Ruptured and Crippled.

Age: 20 of the patients were under one year; 76 were from 1 to 2 years; 54 from 2 to 3 years. (75 per cent three years or less.)

Size of family: In 54 instances the patient was an only child; in fifty-two there was one other; in forty-three there were two other children in the family. (72 per cent. of the mothers not overburdened with children.)

†Read before the San Francisco County Medical Society, May 2, 1916.

and walking as a general rule, but the factor of stretch upon weakened muscles must constantly be borne in mind. In the case of the upper extremity we must take care that a weakened deltoid or other muscles which hold the humerus in place are not stretched by the weight of the arm. The foot should be in dorsal flexion to ninety degrees with enough inversion and adduction to maintain the normal plantar arch; the knee should have about ten degrees of flexion, the thigh flexed about ten degrees with the hip and abducted and externally rotated about fifteen degrees. When the more unusual paralysis, such as that of the calf or gluteal muscles, is present this posture may have to be modified to avoid stretching these groups. If we are sure that the lower leg only is affected we may dispense with the splinting of the thigh, but we cannot be positive of this at this stage unless we test the muscles very carefully with the electric current.

During this stage of plaster splinting the apparatus should be so made as to allow of removal daily for the purpose of gentle massage and bathing; otherwise the weakened muscles will rapidly atrophy. This brings up the subject of braces *versus* plaster-of-Paris splints.

When should braces be ordered? The writer believes that they should be ordered and under construction just as soon as the attendant can determine the extent of the primary paralysis. By the term "primary paralysis" is meant the amount of paralysis resulting after the very acute stage is past, that is, after the second week from the onset of the disease until about the twelfth month, to put it arbitrarily; the "secondary" paralysis being that resulting finally after the period of probable recuperation has passed. There is now a tendency on the part of orthopedic men to regard the period during which more recovery of power may occur as longer than formerly was thought to be and that it is to a great extent dependent upon the care of the case during the first two or three months and also upon the overcoming of contracture; even as late as two years after the onset of the disease improvement in power may occur if contractures are overcome.

Anyone who has seen the atrophic effect upon the limbs of a little patient who has been encased in plaster of Paris for many weeks should be reluctant to use plaster in preference to removable and less constricting apparatus. Aside from the benefits of easy removal for purposes of bathing, massage, and muscle training which braces give, they also permit the patient to get about without detriment to the paralyzed part and with benefit to the general health and the nerve-centers by reason of the stimulation which comes from voluntary activity. These statements presuppose that the apparatus is made of as light material as possible and with proper attention to joints to prevent stretching of weak muscles. Unfortunately, braces are frequently ordered and constructed without due supervision on the part of the attending surgeon and are made much too heavy. The simpler the brace the better; all unnecessary leather work and straps should be avoided, as they add to the weight and also to the expense, which latter is an important consideration with dispensary patients. We will not get the results which are possible in these cases until our orthopedic clinics are equipped with an experienced mechanic and an up-to-date workshop.

In connection with the subject of braces, attention should be called to two conditions sometimes inadequately met because the brace is of the wrong type. The first condition is that of paralysis of the tibialis anticus muscle alone with good power in the calf group, common extensors, and the peroneals. Not infrequently one comes across such patients wearing a steel arch support and they have been told that this is all that is necessary. But an arch support cannot take the place of the tibialis anticus, nor will it prevent pronation and abduction of the foot, with ultimate breaking down of the arch of the foot from strain in the abducted position. The tibialis anticus not only helps very much to hold up the plantar arch, it also adducts the foot at the mediotarsal joint and dorsally flexes it as the tibio-astragaloid joint. An arch support can do neither, it can only invert the foot and so will not prevent the action of the peroneal and calf groups. What is needed in such a case is a brace for the lower leg with a bar on the outside attached to a foot plate and a catch in the joint to prevent plantar flexion beyond ninety degrees, full dorsal flexion being allowed as a rule.

Another condition to which a faulty brace is sometimes applied is that form of paralysis in which the tensor fascia femoris, as well as the quadriceps and the lower part of the great adductor are involved, while the sartorius, the gluteii and obturator muscles which rotate the thigh outward and abduct it are strong. In such a case a brace going only to the upper fourth of the thigh or even to the groin with a padded ring under the ischium is not sufficient to control the comparative overactivity of the sartorius, the gluteii and the other external rotators of the thigh; consequently the child walks with leg abducted and externally rotated, causing a dragging limp and a list of the pelvis which may ultimately produce scoliosis. This form of paralysis should be treated with a long brace having one outside bar or two lateral bars, the outside one running up as far as a point between the anterior superior spine and the trochanter, where it should be movably jointed with a steel pelvic band and leather strap, the band having peroneal straps attached to it. When the back and abdominal muscles are affected this sort of brace can easily have attached to it a light back brace, *e. g.* "Taylor assistant," at the pelvic band.

Electricity and Muscle Training.—How soon should these measures be instituted? Certainly not in the acute stage, and in the subacute stage they should be carried out very cautiously, the duration of the electrical stimulation or the muscle exercise being very brief and very gradually increased according to the type of response to these stimuli; this can be observed and estimated by watching the character of the contraction of the muscle during the course of the treatment. As soon as the response in the muscle-fiber requires more current or the contraction wave becomes more sluggish or the patient less keen in the voluntary movements, the exercise should be discontinued. Lovett advises such treatment only three times a week. He has also contrived an apparatus for estimating the strength of the muscle accurately and regulates the exercises according to the degree of response thus measured from day to day.

Electricity has no effect upon the anterior horn-cells or nerve-trunks so far as we know. It is simply a convenient means of exercising muscle-fibers. Electricity and muscle training undoubtedly have a valuable place in the treatment of infantile paralysis during the subacute and chronic stages and should be more often used, especially muscle training. There is less danger of doing harm by fatigue

of the muscles with muscle training than in the use of electricity, because a child will usually cease to react spontaneously at the point of beginning fatigue, whereas a muscle can be stimulated by the electrical current beyond this point. Muscle training also introduces the element of control by the higher centers and is therefore, I believe, a more rational and efficient form of stimulation; a good thing in spastic cases also.

In dispensary work the electrical treatments are often delegated to a nurse and not supervised by a competent attendant familiar with the case. Thus harm rather than good is done, either because of overstimulation or because of stimulating the wrong muscles, thus increasing the tendency of deformity, mechanical treatment being overlooked because the case is not entirely in the hands of the orthopedic man.

Fatigue may also be brought about by too much voluntary activity of the child. Frequent periods of absolute rest and relaxation should be enforced, especially in the subacute stage. Anything which overstimulates and exhausts the nervous system is detrimental to the recuperation of the local centers involved in this disease.

Treatment of Deformities.—What has already been said comprehends the prevention of deformity. There remains to be considered the correction of deformities which have occurred from inadequate treatment or neglect. Deformity is primarily due to muscle contractures, and secondarily to ligamentous strains and bony distortions from postural strain. To remove the former cause we may resort either to forcible manipulations with plaster dressings or to tenotomy and tendon lengthening. It would seem to the writer that forcible manipulation is bad treatment, and that gradual stretchings are an unnecessary waste of time. These procedures involve the return to plaster-of-Paris dressings for prolonged periods, thus hindering activity and the nutrition of muscles and bones which might be properly exercised in braces. Furthermore, forcible manipulation produces tear of muscle fiber and tendon, and this trauma results in connective-tissue formation which produces a less normal tendon or muscle than before. On the other hand, tendon lengthening, or tenotomy by an open operation within the tendon sheath, has the advantage of promptness in correction of deformity, requires no more than ten days of plaster dressing, and results in as good a tendon and muscle as before. Wherever tendons can be lengthened within their sheaths this should be done in preference to closed tenotomy, and it can always be done with the tendon achilles and the peroneals; also with the tibialis posticus, which, by the way, is frequently almost as potent a cause of deformity as the tendon achilles.

Arthrodeses and Tendon Transplantations.—Whenever a healthy muscle can be transplanted wholly or in part without weakening the most important function of the limb and the period of possible recovery from paralysis has passed, such an operation is worth trying, leaving as a second resource the operation of arthrodesis. Thus a healthy extensor longus hallucis, if successfully implanted beneath the periosteum at the points of insertion of the paralyzed tibialis anticus, will partly replace the latter without spoiling the most essential function of the foot; a peroneus longus tendon may do the same. A peroneus tertius may be inserted in the heel to add power to a weakened calf group, or the tendon achilles may be split and the proximal end of the slip can be inserted into the posterior surface of the tibia beneath the periosteum after the method of Gallie, this serving as a check ligament to dorsal flexion, in calcaneous deformity. Several other examples of the application of tension transplantation might be mentioned.

In deciding upon tendon transplantation, the age and probable occupation of the patient should be considered, also whether or not the ligaments have been so stretched or the bones so distorted that the transplanted muscle will be unable to hold the part in the position best for locomotion. This is apt to be an objection to tendon transplants in long standing or neglected cases of paralysis, for in these cases, in spite of the operation, the patient will require braces.

Arthrodesis has the advantage of doing away with apparatus, of giving a more stable position to the weakened limb, and of permanently correcting a disadvantageous deformity. Its adaptation is more useful in the foot than in the knee or hip. An arthrodesis between the head of the astragalus and the navicular, and between the articular surfaces of the calcis and astragalus is a useful procedure even in cases where a muscle is transplanted at the same time, *e. g.* in talipes valgus, for this operation prevents the lateral mobility of the foot at the mediotarsal joint, doing away with the chance of the valgus deformity recurring even if the transplant fails. To overcome a flail ankle joint, the Whitman operation of astragalectomy is valuable. At the knee, arthrodesis has been done, particularly by Hibbs, but has of late been given up. Most people prefer a movable knee, with a brace, to a permanently stiff one. Davis of Philadelphia has done an osteotomy on the lower end of the femur above the epiphyseal line, setting back the lower fragment and producing a more stable knee for weight bearing in cases of quadriceps paralysis.

The field for plastic surgery in infantile paralysis is still a green one, and full of possibilities. Neuroplastic operations are, as yet, in the experimental stage. The success of these operations depends upon the improvement in technique of the surgeon; to attain this, more opportunities for dissection and animal experiments are greatly needed. But in spite of surgical advances, the after-care will continue to be the important element in success, *i. e.* close supervision and constant vigilance to prevent the recurrence of deformity; the treatment of this disorder will, therefore, continue to be slow, painstaking and conservative, as indeed is true of all orthopedic work, and especially when the nervous system is involved.

PHYSICIANS' BUILDING.

AFTER-CARE OF INFANTILE PARALYSIS CASES.

BY OLIVER H. BARTINE,

NEW YORK.

SUPERINTENDENT, HOSPITAL OF THE NEW YORK SOCIETY FOR THE RELIEF OF RUPTURED AND CRIPPLED; VICE-CHAIRMAN, NEW YORK COMMITTEE ON AFTER-CARE OF INFANTILE PARALYSIS CASES.

THE after-care problem of the cases of poliomyelitis that have had their onset during the past summer has been met in a very able manner by those responsible for it. By the establishment of the New York committee upon the after-care and the many associations cooperating with the orthopedic hos-

pitals and clinics as well as the old-established organizations (some with specially trained nures, social workers, and teachers) that have done excellent service for many years, much benefit will be derived by the victims of our recent epidemic. Many poor and afflicted cripples who would otherwise be neglected and delayed in reaching the hospitals will now be treated and if not cured will at least be so improved that they may later become useful members of society.

It has been a pleasure to see the excellent cooperation between the orthopedic hospitals, general hospitals, and the Department of Health, as well as between the doctors associated in this work. The sacrifices which many hospitals, doctors, nurses, social workers, committees, and contributors have made in this cause are great, but great in return is the good that is being accomplished.

The subject before us presents so many problems, and there are so many social service activities of vital importance that to discuss each of them at length would be impossible within the limits of a short paper. It therefore seems best to dwell briefly upon a number of issues of fundamental importance.

During the active stages of all epidemics the hospitals, physicians, and health authorities devote their full time in combating and controlling the disease. It is not until a later date that they are able to give the time and attention to a thorough and comprehensive study of the problem.

In the early stages of this epidemic, having in mind the inadequate histories of past epidemics of various diseases, especially that of 1907, I advocated, at a meeting called by the Commissioner of Health, Dr. Haven Emerson, the founder of the committee, and later at a meeting called by the Rockefeller Foundation, in which representative orthopedic surgeons of the East were present, that better clinical and social histories of cases of poliomyelitis occurring in this epidemic be made, not only in the Indoor department, but also in the outdoor department. Now that this policy has been adopted by our committee and the hospitals here as well as those in other States and communities, it is felt that within given periods reports upon all or groups of cases of poliomyelitis will be made, that will astonish the most optimistic and will be invaluable to those who are scientifically studying the problem. The medical profession and laity will unquestionably have the most valuable data upon the past epidemic and the after-care treatment.

The many policies as adopted by the committee, if properly carried out, should set a standard and obviate the inadequate facilities of many institutions, their varied fee systems, and their neglectful method of caring for dispensary cases, and their lack of identification of patients roaming from one hospital to another, thus causing a great amount of duplication of work and changes perhaps in the mode of treatment. Possibly the number of patients attending more than one institution is not so great as is commonly supposed and it is also possible that the amount of hospital and dispensary abuse is greatly over-estimated; nevertheless, such information will be available and the foundation erected for a central bureau or clearing house for the supervision of all dispensary cases in the five boroughs of New York.

Too little progress, however, is being made to provide facilities for treatment and care for people of moderate circumstances. Those who are striving in this direction have met with many stumbling blocks. We should give our united support to such a movement, but by so doing we should not overlook the private practitioner, at the same time the private practitioner should not overlook or underestimate the wonderful advantages of this movement for the ill and afflicted, many of whom eventually become crippled financially and their families impoverished as well as in many cases becoming a burden upon the community.

It is well to caution the many enthusiasts who are desirous of opening orthopedic clinics and braceshops to give the matter very careful consideration before their establishment, to discuss the problem with those who are qualified to speak upon the subject, and also to present their needs and facilities to the After-Care Committee. Otherwise they may find ultimately that they are carrying an inadequate and unnecessarily expensive burden.

From the time of the inception of our committee I have advocated that a general appeal for funds should be made by the committee in place of a multiplicity of appeals that would unquestionably be confusing to the public. The After-Care Committee upon recommendation of the Public Health Committee of the New York Academy of Medicine have now adopted this plan. It is now believed that the funds that we hope to raise will be distributed in a manner that will be most beneficial to the associated hospitals and organizations and to the patients.

To provide fresh air or convalescent home care and treatment for these children during a number of summers to come is one of the great problems that will soon be before us. With present and added facilities we shall no doubt be able to meet the situation in an efficient manner. However, we should not delay in giving this matter serious thought and consideration, for it may involve a change of policy in the management of some of the country homes or institutions.

In an address of mine, made previous to this epidemic, upon the history of the Hospital for the Relief of the Ruptured and Crippled, the following statement was made, and this is equally true today: "The work done in improving the condition of patients suffering from paralysis is remarkable; unfortunately in this branch of the work a cure is rarely possible, but by judicious and skillful treatment the condition of practically every paralyzed patient can be improved. It is no uncommon sight to see a child who was carried into the hospital in a totally helpless condition, or who got about only with the assistance of crutches, walk out of the hospital, after some months' treatment, wearing a light steel brace and able again to take an active part in the struggle of life."

Children suffering from paralysis under four years of age, when recommended, are now admitted to our wards, and our Board of Trustees have also made a special ruling that cases that cannot be properly cared for in their own homes can be admitted to our wards until proper provision is made for their care.

It is quite essential that hospitals caring for these cases should have an adequate social service in an endeavor to follow the patient's progress, to study his home conditions, and to see that the physician's directions are followed. Many patients will not return to a dispensary as often as their needs require unless encouraged to do so.

Each institution assuming the burden and re-

sponsibility in the care and treatment of infantile paralysis cases should consider this one of the most important phases of their work, otherwise the patient's progressive improvement may be retarded.

It is my belief that the Social Service should be an integral department of the hospital and, if thought advisable, there should be an auxiliary committee for the purpose of advice, consultation, and other assistance usually rendered by such a committee.

The present epidemic has added materially to the work of our Social Service Department. When the new cases come into the clinic, they are seen by the registrar, who issues them their cards. They are then taken to the department especially prepared for them, and are placed in charge of the Social Service worker. She interviews the parent and secures the social history and any interesting data to be had. Then the child is thoroughly examined by the doctor in charge, who dictates the notes to a stenographer, who later makes the necessary record on the medical history sheet. After the doctor prescribes for the child, the social worker is sure to see that the parent has thoroughly understood directions. She finds very frequently, when they speak little English, that these directions must be repeated several times before they grasp it. They are also impressed with the importance of returning upon the dates stated by the doctor. If they cannot afford the carfare, many coming from great distances, it is provided. The patients are visited in their homes, so the worker may have a good picture of the patient in home surroundings. Sometimes she finds these little patients need extra nourishment or warm clothing, or a pair of orthopedic shoes, which her fund, provided by a generous committee, permits her to secure. She also sees that treatments prescribed by the doctors are followed out.

THE FALLACY OF INTESTINAL STASIS.*

By MARTIN J. SYNNOTT, A.M., M.D.,

MONTCLAIR, N. J.

"Intestinal stasis," so called, was discovered by Sir Arbuthnot Lane of London. I have watched Lane operate during each of three visits to London. He is a very clever and skillful surgeon, and a kind, courteous gentleman. But I don't believe his "short circuiting" operation should be recommended as routine treatment for tuberculosis, gout, diabetes, etc., as I have heard him advise. I know he has not the confidence of his colleagues in England, and in this country his abdominal operations for stasis are rapidly falling into disrepute. A prominent medical authority of Boston regards Lane as the most dangerous man in the medical profession to-day, because he is sincere, and sincere men of strong personalities readily secure followers for unsound theories.

It must not be forgotten that the stomach and intestines functionate perfectly well even when the *x*-ray shows what appear to be marked abnormalities in position.

So-called remodeling operations on the abdominal organs for the relief of such *x*-ray abnormalities will, I believe, soon be given up. Attempts at such remodeling of the human body have not given satisfactory results. Failures have been more numerous than successes, and radical procedures of this nature are, I think justifiable only in desperate cases as a last resort where all other remedial measures have failed and where the patient would prefer death to continued suffering.

At the Massachusetts General Hospital in Boston, by the way, bismuth residue in the intestines up to seventy-two hours is considered perfectly normal, and they have a very active *x*-ray service there, keeping four machines going pretty constantly the greater part of the day.

The best thing Lane has done, in my opinion, is that he has called attention so forcibly to the value of Russian oil in the treatment of constipation. The Curtis belt which he recommends is of very doubtful value. I have had a good deal of experience with it and prescribed it rather often for a time after seeing Lane demonstrate it several years ago in London; but I have long ago lost my enthusiasm for it, and am not satisfied it has produced good results in a single case. Women will not wear it, as it is clumsy and bulky and does nothing that a properly fitting and properly applied corset will not do. Men find it uncomfortable and soon discard it.

As to medical stasis, as ordinarily understood, I am sure in many, if not the vast majority of cases, it seldom exists as anything else than constipation. I have seen this demonstrated over and over again. Patients diagnosed as "stasis" cases have been cured by measures adapted to the treatment of ordinary chronic constipation. Quite recently a patient of mine, suffering from a well-marked case of vagotonia, but also constipated, during a brief absence of mine from home, was advised by a friend to consult a prominent surgeon, who after *x*-ray and bismuth examinations, told her all her symptoms came from intestinal stasis, and that the Lane operation would cure her. She had made arrangements to have this done when I returned and promptly persuaded her otherwise, with the result that she is now well without operation.

The treatment of the symptoms of autointoxication sometimes met with in severe constipation should be by diet, exercises, and medical treatment without recourse to surgery.

We occasionally see stasis cases of the pronounced neurasthenic type which are undoubtedly chemical diseases due to autointoxication from internal glandular starvation, or excess. For some of these patients, gland extract therapy holds out hope of benefit.

The study of intestinal stasis is, I think, a phase of medical evolution brought about by an honest effort of sincere but mistaken men to solve the problems of old age, and to find a remedy for chronic incurable ailments.

Years ago it was the tonsils; when these were removed the arteriosclerosis would be relieved, the rheumatism cured, the arthritis deformans checked. Now we know that the tonsils may be organs of elimination of bacteria and toxins as well as foci of infection and that their indiscriminate removal is not to be advised. As good a man and experienced an observer as the clinical professor of pathology in one of our largest medical schools states that the worst cases of chronic rheumatism and its sequelæ he has seen, have occurred in individuals who had had their tonsils removed in youth; and he unqualifiedly condemns this procedure as lessening one's immunity to infection.

*Discussion of a paper on Intestinal Stasis read at a meeting of the Orange Mountain Medical Society, September 22, 1916.

Next came Metchnikoff with his elixir of life in the form of the culture of *Bacillus bulgaricus*, which was going to cure all human ills. But our present knowledge tells us that the only positive benefit derived from it is the production of Eiweiss milk and lactic acid milk for the treatment of the infectious diarrheas. Then came Lane. But Lane's stasis is rapidly becoming *passé*.

Now it is the blind dental abscess. The chronic patient, no matter what his history or ailment, must have his teeth *x*-rayed. If a shadow is seen, the tooth, even though apparently sound and giving no symptoms, must be extracted. An autogenous vaccine, usually of the *Streptococcus viridans*, which is the fashionable microbe at present, is prepared, and the patient inoculated with this. What could be more simple or scientific!

But this theory loses sight of the fact that most dentists use very crude technique in making their cultures, that special media are necessary for the growth of certain organisms. that the viridans is often found in healthy mouths, that dental pathology is very uncertain; that an encapsulated dental abscess may do no harm, but breaking into it may cause a general septicemia (I have recently seen a case of this kind); that bacterial vaccines do not eliminate toxins; and finally that autogenous vaccines have no special advantage over other kinds, as the most recent immunological research tends to show that vaccines are not specific in disease, and that a colon vaccine may be used successfully in treating typhoid, etc. Thus phylacogens are rapidly coming into their own.

To quote the German cynical philosopher, in spite of all our best efforts, life continues to be at best, a dangerous thing, and very few of us get out of it alive.

Of course, in what I have said, I do not refer to surgical stasis caused by some distinctly pathological process such as bands, kinks, adhesions, cancer, ulcer, etc. Only surgery can, of course, relieve a mechanical obstruction.

34 South Fullerton Avenue.

THE PRESENT TREATMENT OF DIABETES MELLITUS*

By HENRY MONROE MOSES, B.S., M.A., M.D.,

BROOKLYN, NEW YORK.

ASSISTANT ATTENDING PHYSICIAN TO THE KINGS COUNTY HOSPITAL AND THE NORWEGIAN HOSPITAL.

In diabetes mellitus we have primarily a disturbance of nutrition in which the ability of the organism to utilize carbohydrates as it normally does is more or less impaired while in the more severe cases there is added to this a disturbance in the utilization of fats by the body. Treatment is directed toward the making of the urine sugar-free, and toward the prevention or control of acidosis.

To treat successfully any case of diabetes we must give the patient a thorough course of instruction in the nature of the disease, in the differences in foods, the carbohydrates, fats, and proteins; something of the food and the caloric values of these substances; in the effects of breaking the diet rules, and in the examination of the urine for sugar. We must not assume that the patient knows anything about the condition. He must be told that in diabetes he fails to get the full benefit of the starch and sugar eaten, due, we believe to impaired function of the pancreas—that it is frequently observed in people who are obese, or who have gained weight rapidly, and that it sometimes follows intense or long-continued nervous excitement. He must know and realize that faithful treatment accomplishes wonderful results, but half-hearted treatment avails little.

*Read at a meeting of the Brooklyn Medical Association, October 11, 1916.

Naunyn, who is perhaps the leading authority on diabetes now living, says: "From my experience, I consider it highly probable that among the early strictly treated cases which were originally considered severe, but later ran a favorable course, there is many a case for which one must thank this early strict treatment; while, on the other hand, there can be no doubt that the cases which run ultimately a severe course underwent little or no care."

The patient should be taught that as the urine becomes sugar-free the power of the body to utilize carbohydrates improves. If it is not sugar-free, the patient is only holding his own, or more likely growing worse. Attention to diet renders the urine more nearly normal, and this, the patient should understand, is why so much attention is paid to his diet.

Dr. Elliott P. Joslin gives his patients cards on which is a table of the carbohydrate content of many of the commoner vegetables and fruits, together with the protein and fat content of some of the commoner foods. They are advised to obtain for reference the United States Government bulletin on Principles of Nutrition and Nutritive Value of Food, by Atwater, and the bulletin of the Connecticut Agricultural Experiment Station on Food Products.

The diet of a patient is most readily determined by testing the effects of weighed quantities of various foods, and each patient is taught to do this weighing for himself, and should know the quantities of carbohydrate, protein, and fat he is taking daily and whether he keeps sugar-free on it. He knows that he is expected to become sugar-free during the early part of his treatment, and should observe and record how this is done, so that if sugar later reappears in the urine he can follow the same method and again become sugar-free. For this reason it is desirable for sugar to return while the patient is under immediate observation. He is told to eat too little rather than too much, and that all food must be eaten slowly. Especial attenion should be taken in the care of the teeth and gums. Care should be taken in avoiding injuries to the skin, and the body should be kept clean with warm baths. The bowels should move daily, but not be purged. If diarrhea occurs, the patient is instructed to go to bed at once, to apply external heat to the body, and to drink hot water, but not necessarily to stop food. He should exercise freely at short periods daily, never get overtired, and avoid athletic contests and all sources of anxiety and worry. He is told to sleep nine hours or more during the twenty-four.

The patient is taught to use Benedict's test for glucose in the urine, so that a daily examination can be made by him. A notebook is kept in which he records all questions for the doctor. The patients under hospital observation are allowed to mingle freely with one another and to compare conditions and results. Here they see the improvement in the more severe cases and are encouraged about their own condition.

These careful instructions to the patient may

seem too much in detail, but only by getting him interested can results be obtained. He must realize that extreme care is essential to recovery. This is just as important a part of the treatment as any dietary restrictions.

Can we accomplish anything in the prevention of diabetes? We know that in some families there seems to be a tendency to the development of the disease. We should urge all patients to have an examination of the urine at least once a year. This will sometimes allow us to detect the condition early. All the members of a family of a diabetic patient should have frequent urinary examinations. An early diagnosis allows time for much to be done toward the prevention of the development of the disease in those susceptible to it. Instruct the individuals of such a family about the evils of excessive eating, obesity, mental anxiety, nervous tension, and excessive physical strain. Every agency which promotes health and physical development tends to prevent an outbreak of diabetes in those with a tendency to the disease.

The employment of drugs as specifics in diabetes has been common. Many drugs have been used and benefit has been attributed to the use of these. Opium, or one of its derivatives, has been used, perhaps, more than any other drug. It may reduce the quantity of sugar in the urine in a small amount, but it has to be given in large doses, and when we consider the probable duration of life for the individual patient under dietetic treatment we are not justified in giving opium. Aspirin has been used much, but it eventually disturbs the digestion and the benefit of its use does not continue after the drug is stopped. Preparations of the pancreas have not given the results expected and are not used as much as formerly. The *bacillus bulgaricus* has been advocated, but has been found of no advantage in treatment. Calcium in the form of the chloride or lactate has been proposed and used by some of our own members, who report success in keeping the patient sugar-free on an unrestricted diet.

The alkalis have been used in diabetes, not for the glycosuria, but for the threatened coma. In beginning diabetic coma large doses of alkali, well diluted, will frequently change the drowsiness and exaggerated respiration to a more normal condition and apparently work wonders, but the use of the alkalis should not continue over a long period of time. In the ordinary case, however, it is seldom necessary to use the alkalis, as it is safer, more agreeable to the patient, and easier to bring about the disappearance of a slight or moderate acid intoxication by the omission of fat, followed by fasting, than to attempt to neutralize acid intoxication with an alkali.

Joslin says in reference to the use of drug medication: "Drugs may be very beneficial in the course of treatment of a diabetic case, as in any chronic disease, but this is not because of any specific action upon the diabetes. Nevertheless, scores of drugs have been employed with such a purpose. I use none of them, and I think the same custom is followed by those who have had a greater series of cases. If the patient is properly instructed and his interest in his own case sufficiently aroused it will not be necessary to give any drug to retain his confidence."

The Present Dietetic Treatment.—The present dietetic treatment had its beginning at the time of Rollo, an English army surgeon, who in 1796 limited his diabetic patients to a diet of animal food. Various modifications have been made at times by different workers, and our ideas at the present time are the results of the experiences of these men. Bouchardat and Cantani restricted the harmful excess of protein suggested by Rollo and employed green vegetables. Naunyn has wielded a powerful influence in favor of the restriction of protein and also occasional fast days. A number of years ago he called attention to the advantages derived from these fast days and said that one should not fear temporary undernutrition if thereby it were possible to remove the sugar from the urine. In his severe cases it not only made the patient sugar-free, but seemed to increase the carbohydrate tolerance and diminish the acidosis.

Van Noorden agreed with Naunyn that these days were never disadvantageous, and writes: "I make use of these, especially where there is a high acetonuria. It is astonishing how strikingly the acetone falls on a hunger day. Its effect stretches out for a number of days later. In numerous severe cases a hunger day has been instituted every week with excellent results."

In 1911 Hodgson emphasized the necessity of a low caloric intake for diabetics, commenting on the fact that it was not the amount of food that *should* be metabolized, but the amount that *can* be, which determines the amount necessary.

Guelpa of Paris, in 1909 and 1910, reported a series of patients treated by several fast days, combined with purgation, and his method has been followed by many.

With these clinical observations in mind. Dr. Frederick M. Allen experimented extensively on animals, principally dogs, and placed these observations on a proved experimental basis. His treatment consisted of a vigorous fast with black coffee and whiskey until sugar-free; then after 24 or 48 hours begin to feed slowly and cautiously. Any trace of sugar is a signal for a fast day. He published his suggestions for treatment in December, 1914, and since then there have been changes in our ideas of (1) the initial fast, (2) in the necessity for the use of alcohol, (3) in relation of the protein-fat diet in the production of acidosis, and (4) in the use of exercise as a therapeutic agent.

No two cases can be treated exactly alike. Hospital treatment is desired. It is surprising how benign severe cases of diabetes become when under constant supervision. Even in hospitals, however, we have to use constant care to keep some well-intentioned wardmate from giving a hungry diabetic a couple of slices of bread. In long-continued, untreated, severe cases caution is necessary in the first few days of treatment. The sudden breaking of habits of life and diet, together with the excitement of entering a hospital, should make us careful in the radical elimination of carbohydrate and the change to an excessive protein-fat diet. The ease of digestion, as well as the palatability of the changed diet, must be carefully studied, so as not to cause too much effort to the system.

In severe, long-standing, complicated, obese, and elderly cases, as well as in all cases with acidosis, without otherwise changing habits or diet, omit the fat. After two days omit the protein, and then halve the carbohydrates daily until the patient is taking only ten grams; then fast. In simple cases begin fasting at once. Fast four days, unless sugar-free earlier. During the fast the patient is allowed water freely, tea, coffee, and clear meat broths as desired.

Intermittent Fasting. If glycosuria persists at the end of four days, give one gram of protein and one-half gram of carbohydrate per kilo body weight for two days; then fast again for three days unless sugar-free. If glycosuria remains, give the protein as above, with no carbohydrate, for three days, and then fast one or two days, as necessary. This will usually clear up the glycosuria.

To learn the carbohydrate tolerance—when the 24-hour urine is free from sugar add 5 grams of carbohydrate to the diet. Continue to add 5 grams of carbohydrate daily up to 20 grams; then add 5 grams every other day until glycosuria appears.

Protein Tolerance. When the urine has been sugar-free for two days add about 20 grams of protein (3 eggs), and thereafter 15 grams protein daily in the form of meat until the patient is receiving at least 1 gram of protein per kilo body weight.

Fat Tolerance. While testing the protein tolerance a small quantity of fat is included in eggs and meat. Add no more fat until the protein reaches 1 gram per kilo body weight, then add 5 to 25 grams daily until the patient ceases to lose weight or receives 30 to 40 calories per kilo body weight.

The return of sugar demands fasting for twenty-four hours, or until sugar-free. Resume the former diet, except that the carbohydrate is diminished one-half, until the urine has been sugar-free for one month, and it should not be increased more than 5 grams a month. Whenever the tolerance is less than 20 grams carbohydrate fasting should be practised one day in seven. When the tolerance is between 20 and 50 grams carbohydrate, upon the weekly fast day 10 grams carbohydrate and one-half the usual quantity of protein and fat are allowed. These, therefore, are not strict fast days When the tolerance is between 50 and 100 grams carbohydrate 20 grams of carbohydrate are given with the one-half quantity of protein and fat. This outline has to be modified for the individual—the weight, age, digestion, tastes of the individual, and duration of the disease have to be considered.

The preparation for fasting is to prevent acidosis, as it is easier to prevent than to treat. While it is true that few diabetics develop acidosis on fasting, it is impossible to predict what will occur. Patients who have lived in a fairly comfortable condition, untreated for years, are predisposed to acidosis and frequently succumb to too active treatment within a few days of its commencement. The critical period in the management of diabetes, so far as acid poisoning is concerned, is that in which rapid changes in the diet are being made. All complicated cases, especially those in which the complication involves the kidneys, heart, thyroid, the obese, the arteriosclerotic, and patients about to undergo an operation, demand preparatory treatment, which, as we see, excludes the chief source of acid poisoning—the fats.

Any occurrence in a patient out of the ordinary should arouse suspicion, and we should immediately investigate any of the following symptoms: Anorexia, nausea, vomiting, restlessness, unusual fatigue, excitement, vertigo, tinnitus aurum, drowsiness, listlessness, discomfort, painful or deep breathing. The recognition of these premonitory symptoms of diabetic coma is of the greatest importance, for it is astonishing how insidiously coma steals over a patient. The treatment of threatened coma should be prompt. If this prompt treatment can be carried out without awakening the suspicion of the patient it avoids excitement, which is bad for him. Rest in bed at once is necessary, and warmth should be furnished to the body. The bowels should be emptied by an enema.

In threatened coma fasting is efficacious, due, probably, to sparing the patient's digestion, thus preventing vomiting. It also allows the patient fluids. It improves the tolerance for carbohydrates and thereby tends to overcome the acidosis.

If the alkalis are to be given at this time, give them freely and in generous doses at first. Fifty grams of sodium bicarbonate given within five or six hours at the approach of threatened coma are more efficient than double the quantity six hours later. Alcohol apparently does not reduce the acidosis and its usefulness seems slight in this condition. The patient's heart and circulation should be sustained during this condition with cardiac medication.

The question of surgery and diabetes is of considerable importance. In the last few years the mortality following surgical intervention has decreased, until now there is less need for conservatism. But whenever delay is not dangerous the rule still holds to defer surgical interference. Before undertaking an operation upon a diabetic the surgeon should thoroughly understand the dangers with which the patient has to contend and the elements which favor surgical success. The dangers are four—acid intoxication, slow healing of wounds, exhaustion, and lack of exercise.

The elements favoring surgical success are:

1. Good medical care before and after the operation, which should render the urine sugar and acid free, and keep it so.

2. The method of anesthesia. Every effort should be made to shorten the period of anesthesia and to avoid apprehension and excitement on the part of the patient. Chloroform is contraindicated. Ether has been used with success, but is dangerous. Nitrous oxide or nitrous oxide and oxygen appear to be the best anesthetics. Local anesthesia may be used, but allows of nervous excitement.

3. The employment of asepsis rather than antisepsis accounts for many improved results.

4. The avoidance of trauma is especially urged in diabetics. The greatest care should be used in handling the tissues.

Pregnancy in Diabetics.—A small quantity of sugar in the urine during pregnancy is not uncommon. As a rule in such cases the sugar permanently disappears after confinement, although it may recur with succeeding pregnancies, and untimately a severe form of diabetes may develop. In pregnant diabetics there is during the pregnancy an increased carbohydrate tolerance. Pregnancy is not looked forward to by the physician or obstetrician with much pleasure, although recent treatment is more encouraging in its results.

Joslin, who has followed several cases through pregnancy, has arrived at the following conclusions:

1. It is necessary to have the patient under constant supervision through the course of the pregnancy and for months and years after confinement, because it is not uncommon for the sugar to return.

2. Treatment should follow exactly the same methods which are employed in the treatment of the usual case of diabetes, with special care in regard to the fat in the diet.

3. Even when sugar appears to a slight extent in pregnant women it should be carefully watched and controlled by diet.

4. The advantages of a cesarean section should be borne in mind.

5. Ether anesthesia is not so safe as gas and oxygen. If ether should be used, as brief an anesthesia and as little ether as possible should be used. Local anesthesia should be considered.

6. Many statements occurring in the literature of pregnancy and diabetes must be revised. Pregnancy in diabetes does not demand immediate abortion, even if acidosis is present. If pregnant diabetic cases are suitably managed they will very likely abort less frequently. Nursing is not contraindicated following confinement, for the diversion which it affords the patient may offset the extra demands thrown upon the metabolism. The next few years may show that pregnancy may take place in diabetic patients far more readily than has been supposed.

I wish to take this opportunity to thank Dr. Elliott P. Joslin for his courtesy to me in allowing me to see some of his patients during the past summer. The above treatment follows his present method of caring for his patients. Acknowledgment is made also of the use of the writings of those who are doing research and clinical work in diabetes mellitus.

4 Lefferts Place.

THE RÔLE PLAYED BY FEAR IN DISEASES OF THE STOMACH AND INTESTINES.

By LOUIS HENRY LEVY, M.S., M.D.,

NEW HAVEN, CONN.

The relationship of the element of fear to disease is well recognized and has an important bearing from the standpoint of diagnosis and proper treatment. Patrick (*Jour. Amer. Med. Assn.*, 1916, LXVII, 180) has described the rôle played by fear in nervous diseases and the case records of almost every physician contain other instances.

In the consideration of the part played by fear in the production of disease there must not be confused the symptoms of the various ailments as described by the neurasthenic or hysterical individual. These form a series of cases by themselves in which the phobia factor is a minor one. The cases in question are those in which the patient, always normal and well, seems suddenly to have become obsessed with the idea that he is the possessor of some kind of a pathological process. It is because of the fact that these individuals have always been free from symptoms that their complaints are carefully listened to and a suspicion aroused in the mind of the physician that there exists some definite organic cause. It is on this account that the fears of the patient are often increased, especially when he has been informed that from the symptoms there exists a possibility of the lesion in question.

The patient who acquires such a phobia is often of an intelligent type, one who more than the average individual is conversant with medical terms and phrases. As a rule it is an individual who either, through the perusal of medical literature or in the course of conversation, becomes acquainted with some of the symptoms characteristic of organic conditions. It is the case of a little knowledge producing considerable harm.

The public, as a whole, at the present time is better acquainted with medical matters than it has been at any previous time. This is due to the greater publicity given by hygienists and public health officials to the preventable diseases. Education, such as this, of the public is without doubt of inestimable value and has been the means of decreasing the death rate in several of the infectious diseases. It will also in the near future by the earlier recognition of symptoms produce almost as good results in other conditions, such as carcinoma. However, with the repeated precautions to watch out for certain symptoms there has been aroused in many an overcautiousness with the result that some of the ordinary minor ailments are often magnified to unusual proportions and interpreted wrongly by the person possessing them.

Another means of creating such a phobia is contact with a patient who has had symptoms of an incurable or serious condition resulting in death. Even knowledge of such a patient may result in producing fear in another person in whom one or more symptoms may arise. The process of reasoning is a simple one. It is well known that the deceased had definite symptoms of a certain kind and that after a varying period death ensued. Hence it is assumed that, one or more of the same symptoms being present, a similar condition prevails and may lead to a fatal issue.

As has been stated, the individual is usually one who has always been well. As a result of indiscretion or exposure an unfamiliar and disagreeable sensation will arise in some part of the body. Should this symptom recur or persist for any length of time the mind becomes focused on it. Attempts at removal by wrong methods resulting in failure initiate the fear and should these symptoms simulate those of some other case known by the patient, the fear is strengthened. With the increase of the fear new symptoms of psychic origin will arise and the symptom complex will be complete. Sleeplessness will result; the appetite will be lost; less food will be consumed, and following this there will be a marked decrease in weight—all tending to substantiate in the mind of the patient the fear of the presence of some malignant or hopeless disease.

Perhaps no field offers a better opportunity for the display of fear than the gastrointestinal tract. This is due to the ease with which the different parts may be disturbed. The slightest divergence from the regular daily routine of living, particularly in diet, will often produce untoward symptoms that may persist for several days and form the basis of an imagined organic lesion. Even the loss of appetite will predispose to other symptoms resulting in a phobia. Abdominal pains either gastric or intestinal, if persistent, have been the means of arousing unnecessary fears. The frequent belching of large amounts of gas in one who always has been free from this annoying symptom will give rise to apprehensions that there is present a serious gastric condition. Regurgitation of sour fluid, nausea, vomiting with or without bile, all have tended, when occurring at frequent intervals, to arouse fear in the mind of the patient of the presence of an illness of a serious nature.

With the intestinal tract, the occasional pain in the atonic intestine often present in constipation, the rumbling or gurgling sound of gas within the large intestine, distention of the abdomen in tympanites, these also have in many cases resulted in the phobia that some malignant disease was present. The presence of blood in the stools due, as a rule, to hemorrhoids, has from its unusual occurrence filled the mind of the patient with thoughts of ulcerations and even cancer, especially when associated with pain.

The treatment of such phobias is not always a

simple one. It is based first of all on the absolute proof that the condition is a phobia and not a true pathological condition. On this account it is often necessary to try every known test. It is only when these prove negative that the patient's confidence should be obtained and there should be described to him the reasons for the absence of any lesion. He should be convinced absolutely and often conviction is obtained only after the various tests have all been demonstrated and clearly explained. The cause for any abnormal symptom should also be removed and conditions brought to normal by both medical treatment and assurances. Each case offers a problem in itself, and hence the mode of treatment depends mainly on the individuality of the patient himself.

The following cases are selected from a large number seen in the private practice of the writer:

CASE I.—B. G., female, age 22. The original complaint was belching of gas which had first appeared two weeks previously, following the overeating of candy and pastry. Up to this time of her life, she had always been well and had never had any symptoms of any illness. With the appearance of the belching she was reminded of a friend of her family who had died following an operation for perforated gastric ulcer. The deceased had had as a prominent symptom, belching of gas. Miss G. became possessed with the idea that she also had a gastric ulcer. She consulted a physician who very indiscreetly suggested the possibility of such a diagnosis. Following this there occurred in rapid succession a feeling of pressure in the epigastrium with a burning sensation of the skin over this area. She also read a household medical advisor on ulcer of the stomach, and the fear that she had an ulcer became more firmly fixed in her mind. The constant worry resulted in insomnia. The administration of large doses of bromide produced a bromide rash which added further fear. Her bowels which previously had always been regular became constipated and could be moved only by the use of very active cathartics. At no time had she had pain, nausea, or vomiting.

Such was the picture when I was consulted. The patient had lost 14 pounds in two weeks, and was in a weakened condition. She came with the main purpose of having her stomach contents examined. The analysis following a test breakfast showed a well digested meal with free acid of 40 and total acidity of 80. Chemically tested there was no blood. The stool was negative for blood and the urine showed no abnormal substances. She was put on antacid treatment. Simultaneously with the medical treatment there was demonstrated to the patient in several ways the impossibility of the presence of ulcer. This required several visits and patience before she was finally convinced that her fears were groundless. One month after her last visit she was married and there has been no recurrence of symptoms after eighteen months.

CASE II.—D. A., age 42, male. His complaint was dull pain, irregular in time of occurrence, in the left hypochondrium radiating around the side to the back. This pain was independent of the time of eating his meals and never lasted over fifteen minutes. There were days when he was free from pain. He was constipated and felt relieved from pain after his bowels had moved. This was the only symptom at the onset. The patient first became conscious of these pains eighteen months previously, immediately following the death of his wife, who had died from carcinoma of the stomach. The fear that he had carcinoma of the intestine became strongly fixed in his mind and he was insistent that this diagnosis be verified and if necessary operative interference be resorted to. During the eighteen months he had made the rounds of several physicians and also a chiropractor and osteopath. He had lost weight, was very nervous, and could not sleep nights. His friends commented on his change in appearance and also suggested to him the possibility of carcinoma. This strengthened his fears.

It was at this time that I was consulted. The duration of the illness without a corresponding increase in the severity of the symptoms almost at once ruled against malignancy. In this case, however, before the patient could be convinced, it was necessary to examine his stomach contents on different occasions and stool examinations were also made. The urine was also examined. *X*-ray pictures of the left kidney and ureter and also of the entire gastrointestinal tract were made. He even insisted on a blood examination which included a complement fixation test for syphilis and a full blood count. All of the tests and examinations were negative. The *x*-ray photograph of the intestines showed an unusual acute bend with a slight twist of the gut at the splenic flexure. The stools had always been very hard, and it seemed plausible to conclude that the pains were caused by the hard stools passing over the sharp bend at the splenic flexure. This diagnosis did not satisfy the patient, and he visited a consultant in another city. Nothing new was learned and a probable diagnosis of appendicitis was made and laparotomy suggested. He visited me again and there was advised the use of an abdominal belt with a pad fitted over the splenic area, regulation of the diet and bowels. These were all tried. The pains gradually disappeared; the patient gained in weight, and after one year there were no further pains. With this change, the fear of carcinoma has entirely disappeared.

Perhaps as good an aid as anything in this case in removing the fear was the fact that the patient was accepted by two insurance companies for large policies after having told them in detail all his fears concerning the presence of carcinoma.

CASE III.—T. S., age 40, male. This patient had firmly instilled into his mind the fear that there was something fundamentally wrong with his stomach. This fear had been present for six years, during which time he had been treated by several men for various gastric disturbances. His only symptom was water brash which occurred at irregular intervals and seemed to come on when he wanted it to occur. At times, after severe retching the water brash contained bile. During the six-year interval every possible test and examination had been made, including several test meals, *x*-ray examinations, stool, urine, and blood examinations, all of which were negative. For an interval of over three months his stomach had been washed daily. At no time had he been placed on a normal diet and his caloric intake was always less than that required for a man of his occupation. As a result he lost in weight and this with the continued treatment strengthened his fear of some serious gastric condition.

When I first saw him I found him to be a very restless, active, and energetic individual. Physical examination was entirely negative. The irregularity of the occurrence of the water brash and his ability to produce it at will, together with the absence of other symptoms ruled against any organic lesion. A test meal examination showed a slight hyperacidity. The possibility that his condition was based on fear, and that the water brash and hyperchlorhydria were part of a nervous manifestation secondary to the fear, was explained to him and he was encouraged to increase the amount of food and gradually to change his diet. When he found that he could tolerate foods that he had been forbidden to eat and had not eaten for several years, his fear gradually subsided until at the end of two months after treatment, his diet was a regular normal diet. The water brash had ceased to occur and he had gained 10 pounds in weight. After an interval of eight months the symptoms have not recurred and he seems perfectly well.

CASE IV.—E. R., aged 50, female. In this case very little progress has been made, due mainly to lack of intelligence on the part of the patient and her unwillingness to cooperate. Two brothers of the patient had died of carcinoma of the stomach, and this had upset her to such an extent that she lost her appetite and would not eat. The color of her skin, which, normally had a slight sallow appearance, became more so. Her change in appearance attracted the attention of her acquaintances who insisted that she, too, might have carcinoma, and advised her to consult a physician. The fear was started in this way, and all attempts to convince her otherwise have resulted in failure. The usual examinations have been made and all have been negative. She has firmly fixed in her mind the fear that she has carcinoma and is going to die as a result of it. Due to this she will eat but little food and has become emaciated and weak and there is little doubt but that the prognosis will be as she has feared. In a case such as this there has come up the question as to whether there exists true fear or whether some form of dementia has not arisen due probably to the death of

the brothers. The idea of the presence of carcinoma is fixed and nothing seems to be able to remove it. Such a case is as much in the domain of the psychiatrist as it is in that of the internist.

1172 Chapel Street.

A PLEA FOR THE PREVENTION AND THE TREATMENT OF WEAK FEET OCCURRING DURING PREGNANCY AND THE PUERPERIUM.*

By JACOB GROSSMAN, M.D.,

NEW YORK.

ALTHOUGH much has been written about the hygiene of pregnancy and the puerperium, in which proper clothing and belts have been described and recommended, very little stress, if any, has been laid upon proper foot wear. Many authorities in referring to the subject, simply recommend a low-heel shoe. Others overlook the topic entirely. It is true that the weak feet occurring during these periods do not differ materially from weak feet in general, still the presence of pregnancy seems to distract attention from the feet, and one is very apt to believe that the various symptoms complained of are the result of pregnancy rather than those of existing weak feet.

That weak feet may be present for a long time without producing symptoms has been demonstrated time and again. It requires in such cases but a little added strain or perhaps a lowering of the general resistance of the patient, such as one would expect to occur during pregnancy, to produce symptoms. The symptoms rarely depend upon the amount of deformity present. A very slight eversion of the heels and heel cords may produce severe suffering and on the other hand a severe pes planus may produce very mild suffering. The relief of symptoms which occurs in the vast majority of the former type of cases, by the institution of proper treatment of the existing weak feet, proves beyond a doubt that the weak feet are responsible for these symptoms.

Many pregnant women, on reporting to their physicians the pain which they experience in the back, thighs, or legs, are dismissed with the statement that this pain is the result of pressure of the presenting part of the child upon the nerves and will disappear after labor. It is true that in a certain percentage of cases of pregnancy, pressure of the presenting part may produce various neuralgic pains referable to the thighs and back, which will disappear upon the termination of labor. In a vast majority of cases, these pains are the result of weak feet. In my observations of a series of 700 cases of weak feet, there were 400 in whom the pain was referable to the back and thighs and not to the feet (*Interstate Medical Journal*, May, 1916). From this one can readily appreciate that weak feet can be present even though the patient does not refer symptoms to the feet.

The mere recommendation to wear low heels is not sufficient, as many of these patients are accustomed to wear high heels and when they attempt to wear low heels they experience a sensation of falling backwards. To compensate for this they must assume an unnatural and tiresome posture forwards so as to balance themselves properly. This type of patient can wear a high heel with comfort and without serious consequence, provided the heel is square.

*Read at a meeting of the Lebanon Hospital Alumni Society, Oct. 3, 1916.

When one considers how important it is for pregnant women to obtain proper exercise, among which walking is the best, one would appreciate the importance of recognizing the presence of weak feet in these cases, so as to institute proper treatment and in that way encourage walking and other exercises. Walking for patients with weak feet is torture, hence they avoid as much as possible this beneficial and necessary exercise. As a result of this, weakness, nervousness, loss of appetite, and many other conditions may arise from the sedentary life which they are compelled to live.

Accidents such as falls resulting in fractures, sprains of the ankle, and miscarriages are not at all uncommon during pregnancy. These are usually associated with weak feet, and very often with improper foot wear.

Some of the patients experience very little or no discomfort during pregnancy and complain of pain during the puerperium. The following is a brief history of this type of case.

Mrs L., twenty-four years of age, primipara. Past history: No complaint referable to weak feet. Present history: Began four days postpartum, when she experienced a severe cramplike pain referable to the right calf. This pain was not relieved by local treatment, such as hot applications, massage, etc. Examination: Disclosed weak feet. There was no sign of inflammation. Treatment: Strapping, which at first only partially relieved the pain. Persistent strapping, however, finally overcame this distressing symptom. Later, when the patient left her bed, proper shoes were preseribed and to date, almost two years after the onset, she has been free from pain.

Pathology.—The pathology of the weak foot of pregnancy does not vary from that of the weak foot we ordinarily meet with. The early and moderately advanced cases usually show eversion of the heels and heel cords and a lowering of the arch as a whole. This eversion varies in degree from a mild to a very marked rolling out of the heels and heel cords.

In the advanced cases the head of the astragalus becomes partially dislocated inwards and downwards from the scaphoid and at times it may articulate only with the latter at the extreme outer part of the head; in consequence, the cartilage disappears from the portion of the bone that is thus exposed and the head forms a marked prominence beneath the skin on the inner border of the foot. The arch of the foot gradually diminishes, until finally the sole is applied flat to the ground. In well marked cases, the anterior part of the foot becomes abducted, and in very severe cases the inner border of the foot may be convex and the outer concave, so that the patient walks more on the inner side of the foot than on the outer.

In very severe cases the peronei tendons may be dislocated from their groove and lie upon or anterior to the external malleolus. In cases of long standing marked changes also occur in the bones; the uncovered portion of the head of the astragalus becomes enlarged, so that it cannot be replaced in position. Sometimes actual bony ankylosis may take place. There may be effusion into the sheaths behind the tendons and in the tarsal joints.

Symptoms.—The symptoms of weak feet rarely depend upon the amount of deformity present; cases with just a slight eversion of the heels and heel cords may suffer severely and on the other hand cases with a severe pes planus may suffer very mildly.

The subjective symptoms are: (*a*) Pain, present in the vast majority of cases, usually varies

from a severe cramplike shooting pain to a dull ache. In a number of cases the pain is not referred to the feet alone, but to points distant, *i.e.* back, hip, knees, thighs, and calves. The pain may be unilateral or bilateral; in some cases when both feet are weak, patients complain of unilateral pain. (*b*) Another group of symptoms which occur quite frequently includes weakness, discomfort, and tired sensation. These are especially evident after prolonged standing or walking. (*c*) Many cases complain of numbness and coldness in the feet. This is usually the result of the impairment of the circulation which is commonly associated with weak feet. (*d*) As a result of all these symptoms there may be mental depression, nervous symptoms, and loss of appetite.

The objective symptoms are: (*a*) The most constant, one can almost say the diagnostic sign of weak feet, is eversion of the heels and heel cords. This may vary from a very mild to a very marked degree. (*b*) In some cases, especially in fleshy patients, there may be a swelling at the outer side of the ankle. (*c*) Muscular spasm or rigidity is very common in the advanced cases. The spasm is due to the shortened and contracted muscles on the outer and upper surface of the feet, the result of the persistent attitude of valgus.

Treatment.—In general we can consider the treatment of weak feet or rather the feet during pregnancy and the puerperium under prophylactic and curative.

A. Prophylactic: (1) Proper footwear. Before describing in detail the shoe which has proven very satisfactory in pregnancy and the puerperium, a brief review of some of the possible conditions which may arise during these periods would not be out of place. We know that the circumference of the legs of many pregnant women vary from one part of the day to the other. Women will arise in the morning with very little or no swelling of the legs and as the day advances swelling appears. Very often associated with weak feet is a breaking down of the anterior arch. At times patients slip and fall, sustaining sprains and fractures; again they may trip because their heel catches in carpet, rug or their dress when they ascend or descend stairs. The added strain of pregnancy may aggravate an existing valgus of the feet, or if one is not present, produce one in a foot which has already been abused by improper foot wear. A proper shoe to obviate these conditions and accidents should be constructed as follows:

(*a*) There should be an expansion top to compensate for any degree of edema. (*b*) An eighth of an inch elevation in the inner border of the sole and heel to overcome the valgus or prevent one. (*c*) A cross bar of an eighth of an inch in the anterior metatarsal transverse arch to relieve and prevent metatarsalgia. (*d*) A cushion rubber lift in the heel between the top lifts and the under lifts to give soft and jar-relieving steps when walking. (*e*) A special anti-slip finish to the bottom of the sole and heel so as to prevent slipping and subsequent injuries (*f*) Rounded heel edges to prevent catching in carpet, rug or dress in ascending or descending the stairs. (*g*) Must be built on anatomical principles so that the body weight bearing is evenly distributed on the feet. (*h*) The heels must be of the height most comfortable to the patient. (*i*) Should be built so that they can be worn all day without requiring a change to low cut shoes or slippers.

The shoes which we prescribe and recommend, fulfill these requirements and have proven very satisfactory. They are designed for us by Mr. Max Deutsch of this city.

2. Exercises. Exercises should be practised twice daily and should not be carried to the extent of tiring the patient. Walking should be encouraged as much as possible.

Tiptoe exercises: The patient places the limbs in the attitude of moderate inward rotation, raises the body on the toes to the extreme limit, the legs being fully extended at the knees, then sinking slowly, resting the weight on the outer borders of the feet in marked varus, repeating about twenty to thirty times. This exercise if practised faithfully is all that is required.

B. Curative: The two types of weak feet which we commonly meet with in pregnancy and the puerperium are the spastic and the nonspastic. In the nonspastic passive motion of the foot is painless and free to the normal limit. In the spastic type passive motion is painful and restricted. The treatment of the nonspastic type consists of proper shoes and exercises. As a rule these suffice; at times it is necessary to supplement these with Whitman's braces.

In the spastic type of weak feet strapping, shoes, and Whitman's braces are necessary. A very good method of strapping follows; one end of a strip of adhesive plaster, about 15 inches long and 3 inches wide is applied to the outer side of the ankle just below the external malleolus; the foot is then adducted as far as possible and the plaster is drawn tightly beneath the sole up the inner side of the arch and the leg; it is kept in this position by one or two plaster strips about the calf. Narrow strips are then applied about the arch and ankle in a figure of eight manner. Strapping should be done twice a week and continued until the spasm and rigidity have been overcome. When this has been accomplished the brace and proper shoes should then be prescribed.

Conclusions: 1. All cases of pregnancy should be instructed as to the proper care of the feet.

2. Prophylactic measures should be instituted, regardless of the presence or absence of weak feet.

3. Where neuralgic pains in the limbs, back, sciatic region, edema about the ankles are complained of, the presence of weak feet should be eliminated.

4. Only by the institution of prophylactic and early active treatment can we hope to prevent untold suffering in one of the most trying periods in the woman's life.

1051 Boston Road.

REPORT ON AN OLD CASE OF PARENCHYMATOUS NEPHRITIS.

By FRANK MACKIE JOHNSON, M.D.,

Boston, Mass.

In the Medical Record of May 20, 1905, I published an article entitled "Cystoscopy and Renal Lavage," citing the following case:

Mr. E. H., age 61. History of illness of more than two years. Principal symptoms had been headache, nausea, indigestion, weak heart, dropsy, partial inability to walk, loss of flesh and strength. Had received treatment from many physicians and had been told when he was in some hospital that he had but a short time to live. There was a disfiguring skin eruption on his face. He had taken large quantities of digitalis and iron. On examination, a stricture of the urethra was

found. This was dilated. The prostate was enlarged. Urine examination showed the case to be one of chronic parenchymatous nephritis, chronic catarrhal cystitis, and chronic prostatitis. There was a fairly large amount of albumin present.

The bladder was treated by boracic acid washes and injections of protargol, mild solutions of silver nitrate, argyrol, etc., then cystoscopy was performed. The examination of the left and right urines showed chronic parenchymatous nephritis. Both kidneys were in about the same condition. After lavage, ½ to 1 per cent. of protargol was injected slowly. In all there were some eighteen cystoscopies and in the interim bladder washes of boracic acid, silver nitrate 1/5000, etc. Salol, alkalies, urotropin, piperazin, *et al.* constituted the internal medication. Digitalis I did not use. The patient showed marked improvement, was able to resume work, had a good appetite and gained sixteen pounds. His flesh became firmer, right and left urines showed less albumin, and casts almost disappeared.

Eleven years have passed, and it is now 1916. During this time he has been up and about, and feeling quite well. At different times I have given him bladder and renal lavage. The stricture has entirely disappeared, so cystoscopy is not difficult. Soothing diuretics, tonics, urotropin have been more or less continued.

Four years ago he had a hard attack of grippe. This caused an added irritation of both bladder and kidneys, and affected the heart's action. Small doses of strophantus eliminated this new feature. He is now 73 years old; his urine shows more albumin than when I was treating him constantly, and casts have appeared again. Realizing that his condition is a serious one, in spite of his assertion that he feels well, I advised him to resume the bladder and renal lavage. For some time past I have obtained remarkably good results in chronic cystitis, pyelitis, pyelonephritis, etc., from bladder washes of warmed mild solutions of boracic acid, followed by injections into the bladder of 2 to 4 c.c. of colloidal iodine. I gave these treatments every day, at first, and then three times a week; also capsules of this iodine internally, one t.i.d. Up to this time I have believed that the improvement of condition after lavage was due to the better drainage rather than to the medicament used. I am now giving him bladder washes of boracic acid, followed by injections of the iodine—about 4 c.c. After lavage of the kidneys I inject this colloidal iodine very slowly and carefully, a little at a time, using in all 1 to 2 c.c. Internally, he is taking the iodine capsules and nothing else.

Both urines have cleared and the albumin has decreased. Also the good after-effects of the lavage are more lasting. While I do not expect to make a cure, I am more than pleased with the results obtained. And these results have been obtained quickly. It is my firm conviction that if I had been able to use colloidal iodine years ago my report of to-day would fully demonstrate that in iodine we have an agent of real and positive value.

In the light of a newer experience, with cases that show real improvement and many that have been cured, I advise the employment of iodine locally and internally in diseases of the bladder and kidneys, when lavage can be given. The treatment should be begun as early as possible.

A few suggestions in the use of this medicament: The iodine used locally should be warmed; catheters and syringes being dry and sterile. The bladder and urethra should be made dry so far as this is possible. Lubricants should contain no water.

One case, however, does not prove a theory. The object of this paper is to report a case watched and treated for eleven years—one looked upon as incurable; also to emphasize the remarkable results obtained with colloidal iodine. May I make a request that some of my readers test the method mentioned, and give to the profession the result of their experiences?

43 Tremont Street.

Medicolegal Notes.

Offenses Involving Moral Turpitude.—In proceedings to revoke a license to practise medicine as an osteopath in the State of Washington, it appeared that the defendant was charged with having been convicted of an offense involving moral turpitude by using the mails to give notice to cetrain persons named when, how, and by whom and by what means an abortion could be performed. The Washington Supreme Court held that the statute providing for revocation of a physician's license for unprofessional conduct and including conviction of an offense involving moral turpitude, in which case the record of conviction shall be conclusive evidence, is a valid enactment. If conviction of an offense involving moral turpitude is shown there is no discretion in the board of medical examiners. The term "moral turpitude" is not so vague and uncertain as to render the act unreasonable and void.—State Board v. Harrison (Wash.) 159 Pac. 769.

Identification of X-Ray Photographs.—The admission of *x*-ray plates in evidence rests fundamentally on the theory that they are the pictorial communication of a qualified witness who uses this method of conveying to the jury a reproduction of the object of which he is testifying. This being true the *x*-ray plates must be made a part of some qualified witness's testimony, and the witness should qualify himself by showing that the process is known to himself to give correct representations, and that it is a true representation of such object.—Bartlesville Zinc Co. v. Fisher, Oklahoma Supreme Court, 159 Pac. 476.

Privileged Communications—Mental Capacity.—In a suit to set aside a will because of the testator's mental incapacity the California Supreme Court holds that a hypothetical question to the testator's family physician calling for an opinion regarding the testator's mental capacity was correctly excluded under the California statute providing that a physician cannot, without the patient's consent, be examined as to information acquired while treating the patient.—*In re* Ross's Estate, 159 Pac. 603.

Father's Liability for Operation on Partially Emancipated Child.—In an action by a physician and surgeon to recover for a surgical operation and attendance on the seventeen-year-old daughter of the defendant, Cox, it appeared that the latter formerly lived at Chattanooga, but about three years before the occurrence involved he had removed to the adjoining county of Bradley. Two of his daughters remained in Chattanooga to earn their own living. This they continued to do without aid from their father. They were boarding at the Y. W. C. A. building when the younger became ill. The plaintiff was called in by the matron, and, after prescribing for her for a time, decided that an operation was necessary to remove an ovarian tumor. The patient's sister telephoned the father that the doctor advised an operation. The doctor had stated that the operation would be a slight one, and when the father inquired whether an incision would have to be made the daughter replied that it would not, and that the operation would be a slight one. The father replied, "Well, then, if it must be done, it must be done." The daughter responded that her sister would go for the operation the next day. This assent of the father over the telephone was not communicated to the doctor until after the operation. It was held that there was only a partial emancipation of the sick daughter, and a promise on the part of the father to pay for the operation was implied by law. "Emancipation" of a child is the relinquishment by a parent of control or authority over the child, conferring on the latter the right to his or her own earnings and terminating the parent's legal duty to support. It may be express, as by voluntary agreement of parent and child, or implied from such acts and conduct as impart consent, and it may be conditional or absolute, complete or partial.—Wallace v. Cox, Tennessee Supreme Court, 188 S. W. 611.

LESSENING THE DIFFICULTY OF CARING FOR DIPHTHERIA CASES.

CONTAGIOUS diseases always have been, and probably always will be, the *bêtes noirs* of the general practitioner. In the first place, there is the difficulty of diagnosis. The average medical school curriculum, admirably planned and balanced as it is nowadays, must necessarily, in its crowded four years, offer scant time to be spent on this particular subject. Cases may be very scarce in the hospital connected with the medical school at the particular time when the student is attending clinics. He goes then into the arena of active practice often poorly equipped to differentiate diphtheria from quinsy, chickenpox from smallpox, and scarlatina from a digestive erythema. In the second place, there is the difficulty of the family. The diagnosis of a contagious disease means excessive inconvenience to the household and the young practitioner holds his perilous course between the Scylla of losing the family practice forever with a wrong diagnosis and the Charybdis of delaying the report of the case too long, subjecting others to the disease and perhaps coming himself into serious conflict with the health authorities. In the third place, there is the diplomacy amounting almost to equivocation necessary if the physician would keep such cases on his daily visiting list and still retain the rest of his practice, particularly the children. In the fourth place, there is the difficulty of preserving quarantine; and in the fifth place, not to be too prolix, there is the problem of discharging the case from quarantine, not too soon from the view-point of the health officer and not too late from that of the family.

Let us consider briefly a case of diphtheria. In addition to all the drawbacks just mentioned the doctor hesitates, in the case of a family in poor circumstances, to make the diagnosis of diphtheria too readily on account of the cost of antitoxin. The family in question may be so poor that such an expense would be ruinous, especially should the case turn out not to be diphtheria after all, and yet too proud to accept the antitoxin from a charitable organization. Leaving out of consideration such a situation, however, in diphtheria we have, besides the ordinary disadvantages of contagious disease, the presence of what might be called a laboratory form of the disease. The health regulations of nearly all cities require the submission of cultures from the throats of diphtheria cases and one or more of these must be negative before the case can be discharged from quarantine. We are all familiar with the discouraging case which goes along showing plus culture after plus culture long after the clinical signs of the disease have disappeared.

In Public Health Reports for November 10, Assistant Surgeon Newton E. Wayson has reported a study of two diphtheria epidemics, one in West Virginia and one in Washington, D. C., with especial reference to the relation between morphology and virulence, in other words, to see how far a laboratory diagnosis of diphtheria could be relied upon in endeavoring to ascertain whether or not an individual was actually harboring germs capable of producing diphtheria. Thirty-seven cases were studied, the virulence being tested on guinea-pigs of from 200 to 400 grams in weight by injecting with pure broth culture of the organism, after two days growth at body temperature.

Not to go too much into detail regarding the various laboratory methods used by Dr. Wayson, his conclusions are well worth reporting. He decided that a test of virulence by injection into guinea pigs was a more practicable way of controlling diphtheria carriers than the method commonly in use in that it was more reliable and required less time. He also found that the solid-staining types of the diphtheria bacillus are usually avirulent, and that morphology alone is an insufficient index of the virulence of the organism. It is hardly necessary to point out the application of these results. They mean that the method commonly used by health departments in determining whether or not a case should be retained in quarantine is longer than is really necessary and furthermore that a case may show the organisms in the nose and throat and still be perfectly harmless. Surely the adoption of the guinea-pig method would result in pleasing our patients and their families by avoiding in many instances long isolation of children who feel perfectly well and who have long since ceased to show any clinical signs of diphtheria. Then too we would be able to deal in a more intelligent manner with so-called "carriers" when such occur in our practice. It is always irksome to an individual to be shut up for periods of time varying from a few days to many weeks merely because he happens to have germs in his nasopharynx. With this newer method we shall be able to tell quickly whether or not such germs are virulent and if they are not the alleged carrier can go on his way rejoicing.

FATIGUE, AND ITS EFFECTS ON EFFICIENCY.

A MALE or female of the human species, of youthful or adult age, is capable of working efficiently only for a certain length of time. Work done when a person is physically or mentally tired is not effective, and is often worse than useless. However, the fact must be taken into account that different individuals have varying degrees of endurance. Some can continue to labor effectively for a far greater length of time than others. It is a ques-

tion largely of mental and physical virility, and also, to some extent, an acquired habit. But there is a limit to the power for doing efficient work of every one, and, speaking generally, long hours of work are not conducive to good results, from whatever aspect the matter may be regarded. Physical work which calls for little or no skill can be persisted in without detriment to the quality of the work done for a much longer period than skilled work, and this result obtains, of course, more surely if such work is performed in the open air or under favorable sanitary conditions. Work which for its effective performance requires concentration of brain power is doubtless the most severe tax upon the resources of both mind and body.

According to Professor William Stirling, who has recently been giving a series of addresses on the subject, published in the *Medical Press* of Nov. 6 and 8, fatigue expresses itself in a loss of excitability, a diminished capacity for work or "output." The sense of fatigue, however, may not run parallel with the diminution of output. In mental work, decided sensations of fatigue may be experienced when the objective record shows that increasing amounts of work are being done. The output may be falling and there may be absence of the sensations of fatigue. Overactivity without sufficient and timely periods of rest leads to fatigue, but fatigue sensations are not to be taken as a direct index of the nature of fatigue. These sensations are Nature's warning signals, fatigue itself being a complex of sensations. Stirling puts fatigue down as due to two causes: (1) The using up of organic force or energy, and (2) The wear and tear of the organs which are overworked. Matter and energy are used up, restitution does not keep pace with waste, and there is a run on capital.

Perhaps the most instructive and valuable part of Stirling's paper is that which deals with industrial fatigue, and he points out the very obvious truth that in many factories the environment of the workers leaves much to be desired. It stands to reason that those who work in an overheated and moist atmosphere are far more apt to become fatigued than workers in healthy surroundings. In fact, such conditions lead to a disinclination or actual inability to perform effectively active muscular or mental work. The mental activities, indeed, are kept at a high pitch and both muscular and nervous activity are largely governed by the speed of the machine which the worker has to tend, while the noise is a most disturbing factor.

In Great Britain, at the present time, the question of fatigue in relation to efficiency is prominently brought to the front in regard to the manufacture of munitions. It is of the utmost moment to the successful prosecution of the war that munitions be turned out quickly, and in the endeavor to effect the object on an immense scale there has been a tendency to overwork. As said before, a fatigued person is incapable of doing good work, and good work is essential, quite as essential as speed, in the manufacture of munitions. The question of munition workers has been probed of late and it is found that hours of even moderate labor incontestably lead to fatigue, and consequently to lowering of output. The daily cumulative strain gradually but surely tells, the mill grinds slowly but effectively, the machine employed in many cases setting the pace, and in the "speeding-up" process the worker must draw more and more on his energies to keep up with the rhythm of the untiring machine.

But working at high pressure for some length of time produces not only fatigue but sickness. As Miss Hutchins has pointed out in her work, "Women and the Industrial Revolution," there is a close connection between working overtime, fatigue, and certain types of nervous diseases. Fatigue both causes disease directly and predisposes to disease in general. Stirling quotes Miss Goldmark to the effect that in the blast furnace industry of the United States, 88 per cent. of the 31,321 employees are regularly kept at work seven days a week, and young boys of fourteen may still be employed all night long in Pennsylvania.

With respect to the employment of girls and women, the British Munitions Commission are satisfied that the strain of long hours is serious, and are of the opinion that work in excess of sixty hours per week ought to be discontinued as soon as practicable. It has been proved that youths working for 70 hours a week turn out less work by 40 per cent. than when their working time has been reduced to 57 hours a week. The problem to be solved is to insure the maximum of output with the minimum of fatigue. This is from the economic standpoint. The problem from the public health point of view is even more important, for it concerns intimately the health of the race and the welfare of the nation. Overwork brings an over-fatigue which induces disease and which tends to the degeneration and deterioration of a population. Moreover, fatigue is an incentive to the use of alcoholic stimulants, another potent cause of race degeneration. Thus it would seem that from all standpoints overwork is a colossal blunder but one into which all industrial nations have fallen. Proper periods of rest and repose, especially in the case of the young and of women, are physiological and economical necessities, and the country that lavishly and extravagantly uses up her human material with the sole object of attaining industrial supremacy is doomed to decay. After all, it is upon a healthy stock that a nation mainly depends, and therefore it behooves us to see to it that men and women are not broken upon the wheel of commercialism.

TOXEMIA OF PREGNANCY.

When toxemia of pregnancy was first described it was thought to belong to the first seven months of gestation. In the latter months, and especially at or soon after labor it would have been hardly possible to think of any toxic process but eclampsia. To-day it is recognized that toxemia, in the sense of an acute lesion of the liver, may appear in close connection with labor, so that we are justified in calling it puerperal toxemia. It is also evident that several quite different conditions may be comprised under this one term. Neither eclampsia nor toxemia in the original comprehension was looked

upon as an infection, but of recent years the possibility that hepatic toxemia could be due to an ascending infection of the gall ducts by *Bacillus coli* has received consideration. In its mildest form it is perhaps expressed as a simple benign catarrhal jaundice, but in other cases the latter is a mere symptom of a much graver condition, a severe lesion of the liver which may be regarded as the preliminary stage of acute yellow atrophy. Aside from the rapidly fatal form there is another in which recovery takes place, yet the patients show notable symptoms of cholemia. In some cases the child is born jaundiced. Also of great interest is the fact that so-called "delayed chloroform poisoning" may readily be confused with post partum toxemia; so that if much chloroform has been given, a diagnosis of the latter would be impossible. To come back to eclampsia, it must be confessed that it is very difficult to distinguish the rare non-convulsive form from toxemia, and the latter is probably the better designation.

At the session last June of the Royal Society of Medicine Phillips described five cases of acute hepatic toxemia, all he had witnessed in 2,000 confinements. All the cases were in primigravidæ, and two ended fatally. In the first, labor was induced when the patient was near term and toxemia appeared 18 hours after delivery (jaundice, vomiting of blood, high temperature). Death 30 hours later. Autopsy showed some biliary obstruction suggesting an enteric infection. The precise lesion of the liver was not determined, but there was beginning acute yellow atrophy. The second patient became jaundiced on the second day post partum. She was almost unconscious—drowsy and apathetic; the liver was sensitive to percussion. Temperature subfebrile. Death occurred in 48 hours, no autopsy. In the third patient labor was induced in the thirty-fifth week. During this period the motions were clay like, and the temperature rose to 102° Fahr. The child was delivered by forceps. Within 24 hours jaundice appeared with subfebrile temperature but no evidences of sepsis. Not for more than two weeks did bile reappear in the stools, the temperature then becoming normal. The other cases were similar to the latter. The author regards the evidence of a mild ascending cholangitis as suggestive. He was in fact so convinced of this that he treated one patient with autogenous coli vaccine. In all the recovered cases the urine was loaded with *Bacillus coli*. To eliminate the possibility of chloroform poisoning as a factor some other analgesic should be used in suspicious labors, such as those in elderly primigravidæ, when there is absence of bile in the stools, etc.

The Height of Specialism.

There is an alleged joke which we have seen in various vestments in divers of the lay periodicals. A patient with an injured middle finger is shown into Dr. X's office. The latter, after a casual glance at the injured digit, says, "I shall have to refer you to Dr. Y, in the next block, who specializes in such cases. My specialty is wounds of the ring finger." We must confess that this burlesque of the present-day tendency of the profession is sufficiently near the truth to register a hit. Many of our conservative members are of the opinion that we will eventually carry our refinements to such an extent that each doctor will become something resembling a skilled mechanic, proficient enough in the details pertaining to that little section of the human economy which he has claimed for his own, but lacking the broader outlook, the comprehensive grasp of the organism as a whole, its material and spiritual needs, which the physician of the old school had. Too bad that Oliver Wendell Holmes is not living to express himself in this matter. The appearance of a large volume* dealing with the umbilicus and urachus has given us pause. We remember the awe with which our textbook on anatomy was regarded in our freshman year at college and it was of approximately the same proportions as the present tome. If we are to be governed by the relative importance of the subjects in question, we shall await a publication dealing with diseases of the stomach about the size of the Encyclopedia Britannica and if some enterprising writer should attempt a work on the nervous system he could fill about a dozen sections of bookcases. Seriously, the monumental work of Dr. Cullen on the umbilicus is excellent and since the stars ordained that it be written it is fortunate that it was undertaken by so able a scholar and surgeon. The subject has been so thoroughly handled as to discourage any one else from treading the same path for many years to come. Surgeons having to deal with hernias of this region or with the annoying infections which prove so difficult to handle will be grateful to the author for his painstaking researches which have been carried on for twelve years, and for the admirable illustrations with which he has illuminated his subject.

Hypertrophy of the Prostate and Senile Involution.

The question of the interdependence of prostatic hypertrophy and senile involution has often been raised and usually answered in the negative, and the counter claim is made that the senile prostate is an atrophic prostate. Leaving out of question the high incidence of hypertrophy in aged men, we may discuss the subject of the "youthful" prostatic, and it may be possible to show that hypertrophy in advanced age represents only a very slow, insidious evolution of a disease originating a score of years earlier. Well developed prostatism may be seen to occur before the age of 40—dysuria, tumefaction, and all. It is a disease of middle life, perhaps of early middle life, which may not become apparent until there is some senile involutional change in the bladder. The disease prevails very largely in the Anglo-Saxon race, with a history of long latency, and in hale and hearty old men, and the tumors removed by Freyer and others are often very voluminous. In an article in the *Gazette hebdomadaire des science médicales* for September 10, Loumeau reports two cases of early prostatic hypertrophy. The first was in a clergyman aged 41, general history negative. Slow urination at times in boyhood was attributed to cold, to which he was very sensitive; but seven or eight years ago and again three

*Embryology, Anatomy and Diseases of the Umbilicus, together with Diseases of the Urachus. By Thomas Stephen Cullen, M.D. Price, $7.50. Philadelphia and London: W. B. Saunders, 1916.

years ago, he noted some aggravation of this symptom until at present he was a marked sufferer from dysuria. There was no residual urine in the bladder, no urethral obstruction, but rectal exploration showed a bilobar enlargement of the organ which was also exquisitely sensitive to the sound. The prostatic urethra was very slightly retracted, enough to cause severe pain and tenderness, but not enough to cause obstruction. Here we have a "young" prostatic in which the hypertrophy must have appeared at least at the age of 38, and perhaps even as far back as 33. The second patient was 44 when first seen. For five years preceding he had suffered from nocturnal erections not relieved by sexual intercourse—in other words, priapism, for which he had come for relief. There had been no history of dysuria, and both urethra and bladder were intact. The priapism was relieved by treatment, but dysuria at once succeeded it. The two affections continued to alternate under the treatment proper for each. As in the first case the prostatic urethra was sensitive and slightly constricted. Rectal touch revealed a small unilateral adenoma of the prostate. This second patient should have been not over 39 years old when his troubles began. Nothing in the least to suggest presenile conditions was present.

Eclampsia and Fractured Basis Cranii.

One of the most extraordinary associations of disease ever recorded recently occurred in Switzerland. We are familiar enough with types of disease or injury which go to show that certain individuals can withstand almost anything, but cases like the one to be related go even further. The case was reported by Schweizer in the *Correspondenz Blatt für Schweizer Aerzte*. The woman after complaining of slight headache, was heard to fall heavily. A large, powerful woman, she lay unconscious for several hours before reaching the hospital with diagnosis of fracture of the base of the skull. No fetus could be mapped out as a condition of hydramnios was evidently present. The os was intact. The possibility of a twin pregnancy was borne in mind. The full bladder was evacuated and the urine contained albumin and casts. To account for so severe a fall in a woman who was simply clearing the breakfast table it was assumed that it had occurred as part of a general convulsion. Several tonic-clonic seizures had happened while the patient was on the examining table. These were mild, but were soon succeeded by others of greater severity. The woman had rallied from her coma, but was confused and restless and high temperature supervened. Cesarean section was elected because of the fracture and to give the child or children a chance of survival. Two children were removed; they were mature, not asphyctic, and both have thrived. Despite the difficulties of examination fetal heart sounds and movements could be perceived. The operation at once terminated the convulsions, and the woman made a good puerperal recovery. Mischief in the brain soon became evident. There were convulsive movements of cortical origin, almost total aphasia, total alexia, and agraphia. She was kept in bed a month and slowly improved, until she was able to leave for home. Seven and a half months after the injury but a single sequel persisted, a cloudiness of the vitreous in the left eye, not noticeable in binocular vision. It had been an early symptom and was evidently posttraumatic. On account of the patient's almost complete recovery much of the case remains obscure. Was there a causal relationship between the eclampsia and the focal symptoms, aside from the results of the accident? This is answerable in the negative. The author believes that in addition to fracture of the base and its immediate consequences there was more or less contusion of the brain substance due to the same violence. The author finds little help from the literature either of epilepsy or of eclampsia. The pregnant woman is almost always recumbent when the first eclamptic seizure appears. The case must remain largely a puzzle, but one thing seems certain, viz., cesarean section has a new indication in eclampsia.

The Milk Supply of London.

The milk supply of London has been unsatisfactory always, and while some progress has been made in recent years in remedying its defects, it is still a very long way from perfect. Some few years ago one of the *Lancet's* Commissioners investigated the matter and pointed out that the milk supply of London was carelessly handled, that the transportation was defective, that it was often sold in small stores in which it was subjected to contamination, and that, on the whole, the system required complete and thorough revision. It was pointed out too that the manner in which the milk supply of New York was handled was superior by far and that especially was this observed in the means of transportation, milk cans in America being refrigerated, a method unknown in Great Britain. Again, milk is not carried in sealed bottles in England, nor is the supervision of the milk in stores in that country strict. The question had been tinkered with by the British local Government Board but no really effective steps have been taken in the direction of improvement. In the London *Times* of September 25 it is stated that the Clean Milk Society of Great Britain is endeavoring to arouse the public to the menace of an impure milk supply. It is demonstrated that, as pointed out by the *Lancet* years ago, the milk supply of London is notoriously dirty from the bacteriological point of view, and the Society has recommended that the New York system of transporting milk in refrigerated cars and of bottling some of it in sealed bottles should be adopted. The whole of the London supply is carried in bulk. The charges brought against the London milk supply are that it is uncertified, there is no standard of quality, nor careful inspection by means of a score-card system as in America. The Society draws attention to the fact that such negligent methods are bad enough in times of peace, but in times of war they may be no less than disastrous when infant life is so precious.

News of the Week

Smallpox Prevalent.—The United States Public Health Service reports an alarming spread of smallpox through nineteen States, during the last week of November 58 new cases being reported in Connecticut, 125 in Cleveland, 87 in North Dakota, 67 in Washington, and 25 each in Virginia and Texas. The unusually large number of cases in Connecticut has caused some apprehension in New York City,

and the Health Department is urging the vaccination of every one in the city. The last outbreak in New York occurred in 1902, and past experience has shown that a return of the disease may be expected in seven to fourteen years, probably because of the neglect during the subsidence of the disease of the precaution of vaccination.

Openings for Psychiatrist.—The Municipal Civil Service Commission will hold an examination, open to both men and women, for the position of physician for the inspection of mentally defective children. Applications will be received up to 4 P. M. on December 16. From the eligible list resulting the Board of Education will fill a vacancy in the position of senior physician at a salary of $2,520 per annum, and the Department of Public Charities three positions of resident physician, at $1,500 per annum and full maintenance, at Randall's Island Hospital and Schools for Children.

Straus Milk Depots.—The report of the work of the Nathan Straus pasteurized milk depots states that during the year 2,000 babies were cared for, and during the summer 2,500 babies received milk.

Manufacture of Radium.—The Federal Bureau of Mines, according to the annual report of its director, manufactured during the year more than one million dollars' worth of radium. This was accomplished through the cooperation of the National Radium Institute, which furnished capital of $300,000 necessary to develop an economical method of extracting the radium from the carnotite ores.

Drug Traffic in New York.—At the hearings in New York last week of the joint legislative committee appointed last spring to investigate the drug-forming habit with a view to proposing remedial legislation, the estimate was made that the number of drug addicts in the city had increased to 200,000. The present law, it was asserted, acts as a bulwark and protection for unscrupulous druggists and physicians, and the committee was told that there was urgent need for new laws as well as for additional institutions where drug users can be properly treated. It is believed that American manufactured drugs are now being sold into Canada and Mexico and then smuggled back into the United States.

Bar Narcotic Drugs.—The New England Association of Boards of Pharmacy, in session in Boston the first week of December, adopted resolutions announcing a determination to suppress illegal sales of drugs in stores within its jurisdiction and to close stores that refused to comply with the State laws and regulations.

Good Health on Border.—"Above the average" is the report made by Col. W. D. McCaw, chief surgeon of the Southern Department, on the health of the troops at the border. Five base hospitals—at San Antonio, El Paso, Brownsville, and Eagle Pass, Tex., and Nogales, Ariz.—reported less than 2,500 beds occupied, and over 2,000 beds empty. The army usually, it is said, considers 33 1/3 per cent. of empty beds a good record.

Sugar Shortage and Infant Mortality.—A dispatch from Berlin states that it has been decided that the increasing mortality among babies in that city is due to an insufficient allowance of sugar, and it has been ordered that every child born after December 1 shall receive an additional half pound of sugar monthly. The allowance up to this time had been 750 grams monthly for each child.

Fake Paralysis Cure.—Upon a plea of guilty to having sold a fake cure for infantile paralysis, a baker of this city was sentenced recently to serve thirty days in the penitentiary. When examined the promised "sure cure" was found to contain the drugs usually put into the proprietary rheumatism remedies, and the seller confessed that until the outbreak of the paralysis epidemic it has been offered as a cure for rheumatism, but that he had decided he could increase his sales by increasing his claims.

Christian Science Sanatorium.—In furtherance of their purpose to maintain a sanatorium where treatment can be administered according to Christian Science theories, the Board of Directors of the Christian Science Church announces that they will establish a fund for $1,000,000 to be used for building, equipment, and maintenance. The sanatorium will be placed in Brookline, Mass., and will be under the immediate supervision of the Christian Science Benevolent Association.

Tuberculosis Day.—By proclamation of the Governor of the State, Sunday, December 10, was named as Tuberculosis Day in New Jersey. The Governor requested that public attention be called at that time to investigations made by the health authorities for the prevention of the disease.

Fresh Air Work.—The Association for Improving the Condition of the Poor reports that owing to increased contributions during the past season it was able to maintain its fresh air work in New York despite the increased expenditures for equipment and nursing made necessary by the quarantines against poliomyelitis. From June 1 to November 1 all the fresh air headquarters of the association were kept open continuously, including three not before used. Altogether 52,017 days of outings were given to 4,428 families.

Personals.—Dr. Carlos Chagas of the Institute for Experimental Pathology at Rio de Janeiro has been invited to conduct a course on tropical medicine at Harvard University.

A correspondent of *Science* states that Dr. H. B. Fantham of the Liverpool School of Tropical Medicine, who has been serving as chief protozoologist of the Allied forces at Salonica, has been seriously ill with amebic dysentery, but is now convalescing, and is again on duty at Malta.

The University of Illinois, College of Medicine, Chicago, announces the appointment of Dr. L. V. Heilbrun as instructor in microscopic anatomy.

Dr. Joseph M. Thuringer of Boston has been appointed professor of anatomy at the University of Alabama, School of Medicine, Mobile, and Dr. Claude W. Mitchell has been made head of the department of physiology and pharmacology.

The Long Island State Hospital of Brooklyn, N. Y., has recently changed its name to the Brooklyn State Hospital, the change being made to avoid confusion of the institution with the Long Island College Hospital. The similarity in the names of the two hospitals has been the cause of much trouble heretofore, in the misdirection of patients as well as of mail, etc.

Home for Nurses.—Announcement has been made of the gift to the New York Skin and Cancer Hospital of the four-story building at 338 Second Avenue, adjoining the hospital, to be used as a home for the hospital nurses. The giver is Mr. W. C. Van Antwerp, one of the governors of the hospital, and the gift is made in memory of his mother. The house will be remodeled to fit it for a home.

Belgian Contributions.—The Treasurer of the Committee of American Physicians for the Aid of

the Belgian Profession reports that the receipts during the quarter ending November 30, 1916, were $11.40, making the total receipts $7,958.26. The total disbursements, including 1,625 standard boxes of food at $2.20, 1,274 boxes at $2.30, and 353 boxes at $2.28, have amounted to $7,310.04, leaving a balance on hand of $648.22. Contributions may be sent to Dr. F. F. Simpson, treasurer, 7048 Jenkins Arcade Building, Pittsburgh, Penn.

Gifts to Charities.—By the will of the late Mrs. Josephine H. Dickman of New York, the sum of $5,000 is left to Dr. Benjamin Tenney of Boston, to be used for such charity or medical purposes as he may select.

The Goshen Emergency Hospital of Goshen, N. Y., receives a bequest of $10,000 by the will of the late H. W. Van Cortland of that city.

The University of Chicago has received from Mr. Frederick H. Rawson a gift of $300,000 for the medical school. The money will be used to erect a new laboratory building.

By the will of the late Col. W. G. Vincent, a bequest of $60,000 made to his wife, becomes available after her death for the uses of the School of Tropical Medicine of Tulane University.

By the will of the late Mr. Jacques Halle of New York, Mt. Sinai Hospital receives a bequest of $5,000, while bequests of $2,500 each are made to the Montefiore Home and the Beth Israel Hospital Association.

Medical Journal Changes.—We regret to learn that the Cincinnati *Lancet-Clinic* has ceased publication. The *Lancet-Clinic* was the product of the consolidation of the *Lancet and Observer* and the *Clinic*, the latter being the first medical weekly issued west of the Alleghenies, and was for many years a journal of high standing and authority.

The Louisville Monthly Journal of Medicine and Surgery has become the official organ of the Mississippi Valley Medical Association and has taken the name of the *Mississippi Valley Medical Journal.*

The *Texas Medical News* has died and been reincarnated as *Medical Insurance and Health Conservation.*

Medical Society Elections.—Tri-State Medical Association of Arkansas, Mississippi, and Tennessee: Thirty-third annual meeting at Memphis, Tenn., on November 23. Officers elected: *President*, Dr. James W. Gray, Clarksville, Miss.; *Vice-presidents*, Dr. H. Rogers Hays, North Carrollton, Miss., Dr. R. W. Griffin, Tiptonville, Tenn., and Dr. Floyd Webb, Turrell, Ark.; *Secretary*, Dr. J. L. Andrews, Memphis; *Treasurer*, Dr. J .A. Vaughan, Memphis.

Eastern Medical Society of New York City: At the annual meeting on December 8, 1916, the following officers were elected: *President*, Dr. I. Seth Hirsch; *Vice-Presidents*, Drs. H. E. Isaacs and G. G. Fischlowitz; *Recording Secretary*, Dr. J. F. Saphir; *Treasurer*, Dr. A. A. Hilkowich.

Ohio Valley Medical Association: Annual meeting at Evansville, Ind., on November 23. Officers elected: *President*, Dr. William Shimer, Indianapolis, Ind.; *Vice-presidents*, Dr. J. Rawson Pennington, Chicago, Dr. W. F. Boggess, Louisville, Ky., and Dr. Meyer L. Heidingsfeld, Cincinnati, Ohio; *Secretary-Treasurer*, Dr. Benjamin L. W. Floyd.

The Harvey Society.—The fourth lecture of the series will be held at the New York Academy of Medicine on Saturday evening, December 16, 1916, at 8.30 P. M., by Prof. Henry H. Donaldson of the Wistar Institute of Anatomy and Biology; subject, "Growth Changes in the Mammalian Nervous System."

Obituary Notes.—Dr. Ivory Lowe of Canaan, Me., a graduate of Albany Medical College in 1862, died at his home on November 26, after a short illness, aged 80 years.

Dr. Philip Mills Jones of San Francisco, Cal., a graduate of Long Island College Hospital, Brooklyn, in 1891, and a member of the American Medical Association, the Medical Society of the State of California, and the San Francisco County Medical Society, died suddenly on November 27, aged 46 years. Dr. Jones was secretary of the Medical Society of the State of California.

Dr. Jacob Brill Peters of Walden, N. Y., a graduate of New York University Medical College in 1885, and a member of the Medical Society of the State of New York and the Orange County Medical Society, died at his home after a lingering illness, on November 23, aged 63 years.

Dr. Ellera J. Whittleton of Webster, N. Y., a graduate of Cleveland University of Medicine and Surgery in 1884 and a member of the Monroe County Homeopathic Medical Society, died at his home on November 20, after a short illness, aged 57 years.

Dr. Joseph Stafford Horsley of West Point, Ga., a graduate of the Medical Department of the University of Georgia, Augusta, in 1870, and a member of the American Medical Association, the Medical Association of Georgia, and the Trop County Medical Society, died on November 17, aged 73 years.

Dr. Frederick James Sanborn of Spencer, Mass., a graduate of Bellevue Hospital Medical College, New York, in 1883, and a member of the Massachusetts Medical Society and the Worcester County Medical Society, died suddenly in his automobile while making a call, on November 20, aged 55 years.

Dr. Adrian Mathews of Providence, R. I., a graduate of Jefferson Medical College of Philadelphia in 1874, and a member of the American Medical Association, the Rhode Island Medical Society, and the Providence County Medical Society, died at his home on November 19, after a long illness, aged 66 years.

Dr. James Albert Breakell of New York, a graduate of Columbia University, College of Physicians and Surgeons, New York, in 1873, and a member of the Medical Society of the State of New York and the New York County Medical Society, died at Cross River, N. Y., on November 18, aged 65 years.

Dr. William Williams of Pittsburgh, Kan., a graduate of the Missouri Medical College, St. Louis, in 1886, and a member of the American Medical Association, the Kansas Medical Society, and the Crawford County Medical Society, died at the home of his brother in Niangua, Mo., on November 14, aged 55 years.

Dr. David Byron Todd of San Francisco, Cal., a graduate of the University of Michigan Medical School, Ann Arbor, in 1871, died on November 20, after a brief illness, aged 69 years.

Dr. Norman Howe Liberty of Mineville, N. Y., a graduate of Albany Medical College in 1912, and a member of the Medical Society of the State of New York and the Essex County Medical Society, was instantly killed in an automobile accident at Ticonderoga, N. Y., on November 13, aged 27 years.

Dr. Claude Bernard Foreman of Kane, Ill., a

graduate of the Missouri Medical College, St. Louis, in 1897, and a member of the Illinois State Medical Society and the Greene County Medical Society, died in the Springfield, Ill., Hospital, on November 27, from appendicitis, aged 40 years.

Dr. WILLIAM HENRY STRENG of Richmond, Ill., a graduate of the Chicago College of Medicine and Surgery, Chicago, in 1907, and a member of the American Medical Association, the Illinois State Medical Society, and the McHenry County Medical Society, was killed instantly in a collision at a grade crossing in Waukegan, Ill., on November 21, aged 38 years.

Dr. CLIFTON MAUPIN FARIS of Sacramento, Cal., a graduate of Johns Hopkins University Medical Department, Baltimore, in 1905, and a member of the American Medical Association, the Medical Society of the State of California, and the Sacramento County Medical Society, died suddenly at his home on November 16, aged 39 years.

Dr. ALPHEUS D. FINCH of Bellefonte, Ark., a graduate of the Medical Department of Vanderbilt University, Nashville, in 1885, died at the home of his son, near Bellefonte, on November 7, aged 67 years.

Dr. EDWARD DARROW of Aurora, Minn., a graduate of Rush Medical College, Chicago, in 1901, died in his office on November 12, from myocarditis, aged 42 years.

Dr. JESSIE VALERIA STAUFFER SMITH of Winterset, Iowa, a graduate of the College of Physicians and Surgeons, Keokuk, in 1892, and a member of the Iowa State Medical Society and the Madison County Medical Society, died on November 12, aged 50 years.

Dr. GEORGE P. MUNSEY of Suncook, N. H., a graduate of Dartmouth Medical School, Hanover, in 1879, died at his home on November 26, aged 61 years.

Dr. C. AUGUST W. SCHWAGMEYER of Cincinnati, Ohio, a graduate of the Medical College of Ohio, Cincinnati, in 1870, and a member of the Ohio State Medical Association and the Hamilton County Medical Society, died at his home on November 11, from heart disease, aged 72 years.

Dr. ANDREW JOHN CRIGHTON of East Hartford, Conn., a graduate of the College of Physicians and Surgeons, Baltimore, in 1891, died at his home on November 28, aged 52 years.

Dr. JAMES F. GARDNER of Capen Bridge, W. Va., a graduate of Bellevue Hospital Medical College, New York, in 1879, was killed in an automobile accident near Winchester, Va., on November 11, aged 73 years.

Dr. EDWIN R. MONTGOMERY of Louisville, Ky., a graduate of the Medical Department of the University of Louisville in 1867, died at North Birmingham, Ala., on November 27, aged 69 years.

Dr. WILLOUGHBY WALLING of Chicago, Ill., a graduate of the Medical Department of the University of Louisville in 1868, and a member of the Illinois State Medical Society and the Cook County Medical Society, died at his home on November 28, aged 68 years.

Dr. DECOU CARPENTER MOULDING of Chicago, Ill., a graduate of Dearborn Medical College, Chicago, in 1906, and of the University of Illinois, College of Medicine, Chicago, in 1909, and a member of the Illinois State Medical Society and the Cook County Medical Society, died in the Augustana Hospital, Chicago, on November 21, following an operation, aged 46 years.

Correspondence.

ETHICS OF LETTER WRITING.

TO THE EDITOR OF THE MEDICAL RECORD:

SIR:—A recent incident gives prominence to the somewhat stupid custom of physicians in not answering letters that are of minor importance which come to them. A man was operated on successfully at a Boston hospital by an eminent surgeon. Later it occurred to him that he would like to make him a present as a token of his appreciation. Accordingly he wrote a very pleasant letter of thanks, without intimations of what he wished to do, expecting that the doctor would respond in some way that would promote a further correspondence. Weeks passed by and no response came, and fearing some mistake, he sent a special delivery letter of warmly expressed thanks. This brought no answer. The check of a thousand dollars that he intended to give him was then torn up, and a feeling of indignation and contempt took its place.

While this may be a very unusual incident, it gives emphasis to the stupid neglect of a great many physicians to recognize the ordinary correspondence which comes to them. Underrating the importance of a letter that calls attention to some fact or brings with it some compliment or suggests some change or even requests for opinions on minor matters, is a reflection on the physician's judgment and ethical sense and always brings with it suspicion of weakness. Two examples illustrate this: A physician and teacher of great reputation rarely writes any letters of thanks for favors and seldom replies to any correspondence. As a result, his judgment is discounted in innumerable ways and his ordinary courtesy is questioned and his personal reputation has suffered more or less seriously. When remonstrated with for this neglect, he gave excuses of want of time and so on. The second example is that of a popular teacher and practitioner who makes it a rule to answer every letter, acknowledge every favor, and respond to every request. As a result, his popularity and esteem among the profession are very pronounced. Every hillside physician, who has written him in a broken, confused way about some matter has received a reply which he treasures as a direct tribute to himself. Even quack drug men, who write sending him specimens are proud of his recognition in the simplest form of a letter.

Physicians, of all others, make a fatal mistake in not adopting the politicians' ethics of answering every voter who appeals to them in any way. The physician is a public man and his affability and courtesy to every one he comes in contact with is a very large asset in his success. To fear a correspondence that may be used in some way in the future against him is stupidity. A trained physician of all others should be able to write clearly and briefly in such a manner that no complications could possibly follow. He should show equal courtesy with the business man or politician who makes correspondence a large lever in his work.

T. D. CROTHERS, M.D.

HARTFORD, CONN.

Tetanus from Ocular Wounds.—Schneider states that about sixty cases of this sequence have been recorded within the past century and adds two personal observations. Apparently few or none of these occurred as a result of the war.—*La Presse Médicale.*

OUR LONDON LETTER.

(From Our Regular Correspondent.)

THE HARVEIAN ORATION—BENEFACTORS OF THE ROYAL COLLEGE OF PHYSICIANS—ENDOWMENT OF RESEARCH—RELATIONS TO ST. BARTHOLOMEW'S HOSPITAL—DR. VAUGHAN-HUGHES.

LONDON, November 11, 1916.

SIR T. BARLOW'S Harveian oration at the Royal College of Physicians, which I mentioned last month, may very well interest you further. It began with a commemoration of benefactors of the college, the first president, Linacre, being the real founder, for it was to a large extent due to his counsel that the charter was conferred by Henry VIII. But he must be reckoned further as a pioneer in the revival of learning and moreover as a physician in the highest sense. The early meetings were held in his own house, which he seems to have presented to the college during his lifetime. He was followed in his office by John Cains, who was elected president no less than nine times and who wrote the "Annals" with his own hand from 1555 to 1572. He was not only a great scholar, but the first teacher of anatomy in this country, an able naturalist, and writer on clinical medicine—witness his careful study of sweating sickness. The next president was Richard Caldwell, who was elected in 1570 and who jointly with Lord Lumley endowed the Lumleian lectureship. In 1600 the president was William Gilbert, the pioneer in the study of magnetism, who has been called the father of experimental philosophy in England and the inspirer of Galileo. He bequeathed to the college his library, globes, scientific instruments, and natural collections. To him succeeded Harvey, whose material benefactions to the college were enormous. In 1651 he had retired, being 73 years of age, but he still held the Lumleian lectureship and offered to build and present to the college a library and museum. In two years these additions, together with a large convention room, were completed and conveyed to the college. In 1656 he resigned his lectureship and added further benefaction to the college in the shape of his patrimonial estate, the value of which at that time was £56 a year. He expressed a wish that an annual feast should be held and an oration delivered in commemoration of benefactors, for which a fee should be paid to the orator, and a salary to the keeper of the museum and library which he had previously founded and furnished. In his will he provided for the completion of any part of the building which might not be finished, and bequeathed his books, papers, and furniture for the meeting-room which he had built. Theodore Goulston was contemporary for a time with Harvey and became a censor of the college and endowed the lectureship named after him which is given by one of the four youngest fellows. Sir Theodore H. Mayerne was also a contemporary of Harvey's, who after a distinguished medical career in France came to England, became a fellow of the college to which he bequeathed his library and was physician to James I and Charles I.

Baldwin Hamey, Jr., was one of Harvey's intimate friends; he served as treasurer of the college from 1664 to 1666 and gave anatomical lectures at the college. In 1651 the tenure of the land on which the college stood being in danger, Hamey bought it and presented it to the college. After the fire of 1666 the college was rebuilt and Hamey contributed to the cost. He also settled an estate in Essex on the college. The Marquis of Doncaster, one of the few honorary fellows of the college, was one of Harvey's friends and one of his sponsors on election to the college. Dr. Croone, one of the original fellows of the Royal Society, was censor of the college in 1679, and one of its most generous benefactors Mrs. Streatfield's endowment of research fund has been completed and £10,000 in 2½ per cent. annuities paid into the names of the two colleges as trustees for the promotion of research in medicine and surgery.

The relations between Harvey and the governors of St. Bartholomew's Hospital were cordial and revised regulations proposed by him in 1633 were at once adopted. These show that he stoutly maintained the supremacy of physicians over surgeons as then was customary. The surgeon was not allowed to perform operations without the consent of the physician and was required to declare what external remedies he applied in any given case. The surgeon visited the patients in the wards, but the physician only did so when a case could not be brought to the great hall.

Dr. James Vaughan-Hughes has died at the ripe age of 95 years. He wrote "Twenty Years of Life in the Victorian Era," in which he recorded his work with Florence Nightingale when he was attached to the medical staff in the Crimea. For his work there he was awarded double pay by Lord Panmure. He had charge for a time of Balaclava Hospital and attended Florence Nightingale when she had camp fever. On her recovery he obtained the loan of Lord Dudley's yacht to take her back to Scutari. Later he contracted cholera and he attributed his recovery to the attentions of Miss Nightingale and her nurses. Notwithstanding his great age, he rode on horseback and drove a carriage and pair until a few months ago.

2. Psychic and Neuropsychic Affections in War. E. Régis.
3. Drug Addiction and Modern Methods for Its Control. Solomon H. Rubin.
4. Acute Primary "Idiopathic" Phlegmonous Gastritis. Emanuel B. Fink.

1. A Clinical Study of the Secretions of the Digestive Tract.—Thomas R. Brown gives a rather thorough report on this subject and states that the neglect of the study of the secretory side is most unwise if one wishes to have a broad conception of the diseased process in many and varied interesting digestive conditions. From the studies which he has presented the writer draws certain conclusions—some physiological, others clinical. Of the former the demonstration of the lack of influence of the gastric secretion upon the character of the saliva; the fact that saliva rich in diastatic ferment is secreted during the chewing of inert substances, stimulating neither to the taste or smell; the independence of rennin and pepsin, the lack of definite quantitative relationship between the pepsin and the hydrochloric acid of the gastric juice, and that in the absence of the normal mechanism of pancreatic stimulation some other mode of calling forth the ferment of this gland, probably nervous in character, is brought into play. From the clinical side, the large number of conditions met with in which the absence of hydrochloric acid in the gastric juice is encountered; the significance of an increase in the soluble proteid of the gastric contents in the diagnosis of gastric carcinoma; the importance of recognizing the

group of gastrogenous diarrheas, and the brilliancy of their treatment with hydrochloric acid; the fact that with a rigorous technique there are low normal limits to the quantity of diastase found in the stool, and that an absence of these ferments is very suggestive of cancer of the pancreas.

2. Psychic and Neuropsychic Affections in War.—E. Régis, of Bordeaux, France, strongly urges the establishment of hospitals for the insane in the army at sufficient distances from the field of operations. He has devoted much of his time to the study and diagnosis of the military psychoses, and finds that in case of need even special pavilions annexed to ordinary field hospitals would suffice on condition that their medical direction was intrusted to specialists. The psychoneuroses or psychoses from moral shock, which predominate in great battles, are essentially acute, transitory and curable in a few days, and no treatment is better suited to these cases than rest in bed. He divides the psychoses into two groups, those found in soldiers who have not been under fire, which are common, and merely supervening on the occasion of war (disequilibrations, degenerations, alcoholism and general paralysis). The second group composed of psychic and neuropsychic affections in men returning from the front and induced directly by battle. Of the former group he studied 62 cases, of the latter 88. It is the latter group of which he gives a detailed account. Among these, the principal psychic disturbances established by study of the cases, were hallucinatory oneirism and mental confusion. While epilepsy is rare, hysteria is common; also functional paraplegia or pseudoparaplegia. He considers that the cause of these conditions is not results from wounds, but emotional shock received in battle or the military life. Even in those wounded it is the emotional shock which precipitates the psychosis. Functional paraplegia following battle must be regarded as the effect of a violent emotional shock. He concludes that the subjects of neuropsychic disturbances should be separated from other patients and placed in a special neurological or neuro-psychiatric service, in accordance with local organizations, reducing to a minimum the chances of intermental action, that is to say, of reciprocal contagion.

3. Traditional Fallacies About Tuberculosis.—Maurice Fishberg believes he is correct when he states that medical literature is apt to contain fallacies based on the assumption that because of concomitance of time and place, two or more phenomena are caused by the same forces. Tuberculosis seems to have had attached to it more than the usual number of fallacies, some of which are not only harmful, but decidedly detrimental to the individual and his surroundings. For instance, Fishberg says that in his long experience as physician for the United Hebrew Charities in New York, he has never observed a case of tuberculosis transmitted from one consort to the other. This in spite of the often unhygienic surroundings of the patients. They have children while sick with tuberculosis and while most of their offspring become infected, the unaffected consort remains so indefinitely. J. Petruschky has recently named "mother immunity" a phenomenon which has been observed for generations by physicians. A healthy woman marries a tuberculous man and bears him children that succumb to the disease one after another, yet she is spared and remains in good health. With reference to children, there is the fallacy of confounding *infection* with *disease*. While extrapulmonary tuberculosis is rather common in children of school age, real pulmonary tuberculosis is rare. Children with tracheobronchial tuberculosis are not all in danger; death due to this cause is so rare that it may be disregarded when formulating prognosis in the average case. Nor are these cases a menace to those associating with them because, as far as is now known, they do not disseminate the bacilli. It is a fallacy to treat every sickly underfed child as tuberculous; even when the tracheobronchial glands are discovered to be enlarged, there is no reason to prohibit school attendance, or to institute prolonged and costly treatment, except such measures as will enhance the nutrition of the child. He speaks further of the fallacies in connection with diagnosis, prognosis, prophylaxis, and treatment.

5. Oxygenated Milk.—Clifford G. Grulee gives an account of the process of producing oxygenated milk in the Presbyterian Hospital, Chicago. It was installed in 1915 by a Danish chemist, N. D. Neilsen, on a plan following the scheme of Doctor Budde in Copenhagen, where it was introduced in 1903. This milk takes the place of certified milk for children and infants, and is distinctly cheaper. The process is as follows: Good raw 4 per cent. milk is treated with hydrogen peroxide, one quart to twenty gallons; it is then heated to 122°—128° F. for one-half hour, being stirred by a fan in the reservoir so that it is kept in motion the whole time. The milk is then withdrawn and bottled hot, and kept on ice until used. This is a preserved milk without any preservatives, because at the end of a half hour's treatment only a trace of the hydrogen peroxide can be obtained. By this process the milk is made sterile and therefore all bacteria are inactive, rendering the milk safe from distribution of pathogenic organisms. The advantages offered by this process are that fresh milk can be obtained at any time of the day or night, its absolute safety, and the fact that it can be kept as long as two weeks at room temperature without souring during the summer months, thus insuring greater safety. Grulee says that theoretically the chemical change is only a destruction of the catalase enzyme in the process of splitting the hydrogen peroxide. However, he found that oxygenated milk cannot be used in the preparation of buttermilk, as it prohibits the growth of the necessary bacteria.

4. **Dermatological Dietetics.**—Ernest Dwight Chipman says that nutrition is upkeep and that it essentially deals with two vital factors, fuel and repair. He gives the caloric values required by men in various occupations and walks of life for basal heat production. In an average man of 156 lb. this will be 70 calories per hour; extra heat produced by the ingestion of food causes an increase of about 10 per cent., making a total of 1848 calories per day. This amount is divided among the different food constituents, namely, protein, carbohydrate, and fat in required proportion. Because of its nitrogen content protein is essential to the processes of growth and repair. In excess of the quantity required for these purposes it increases the level of heat production. As to the kind of protein, Voit would have one-third animal and two-thirds vegetable, though there seems to be no hard and fast rule respecting this ratio. Carbohydrates, protecting the albumin of the tissues from waste better than a similar quantity of fat, are called albumin sparers. A mixture of absolutely carbohydrates, fats, proteins and salts will not maintain life for a long time. The experiments of Osborne and Mendel show that a satisfactory complement exists in a powder obtained by evaporating milk from which the protein element has been almost entirely removed. They found further, in experiments with rats, that when lard was the sole fat element of the diet growth stopped, but when butter fat was substituted was resumed. A minute quantity of some certain substance seems quite necessary in food. It has been found that a group of so-called vitamins exists in the vegetable kingdom and that the members of this group are essential to growth and nutrition of animal tissue. Deficiency of these substances causes beriberi. Pellagra is undoubtedly of analogous origin. The nutritive values of any protein depend largely on the character and the extent of the animo-acids it contains. A knowledge of the basis requirements of nutrition is to be thoroughly understood in order to apply the principles of nutrition to the needs of dermatology. A mean average is necessary in diet lists between the extremes of generalization and detail. Chipman makes three divisions of the dermatoses according to their relationship to diet: (1) Those directly dependent on diet: (2) those in which diet may not be the cause, but in which it is of capital importance; (3) those in which diet may be an indirect factor. Beyond these three groups there remain certain morbid states requiring dietetic care, conditions which are often seen in association with various dermatoses and whose relationships with these dermatoses may be direct, casual or remote. The foodstuffs may act either reflexly, directly, indirectly, through insufficiency of certain food elements, or through excess of certain food stuffs, and through hypersensitiveness, producing a dermatosis according to type developed through any one or more of these conditions. Psoriasis can be much helped by placing the patient on a low protein diet, while eczema will almost disappear when the carbohydrates and starches are reduced. Acne can be controlled on a low starch diet. There are but few specific diets in dermatology, but an accurate perception of the individual's needs, from the standpoint of nutrition, is imperative. Much comfort may often be found in the three simple rules of Brocq: Eat sparingly; eat slowly; rest after meals.

6. **Experimental Endocarditis.**—Detweiler and Robinson have followed up a report of earlier work along this line and in following out the methods advocated by Rosenow they have elaborated a technic which has been thoroughly used and has given splendid results. The method in detail is described, and while recognizing its disadvantages they also consider the advantages far outweigh in results. The organisms used in this series of experiments were obtained from blood in cases of subacute and chronic infectious endocarditis. All of the strains belong to the family of *Streptococcus viridans*. The animal experiments have been confined to an attempt to produce in rabbits a condition analogous to that of the patient from whom the organism was obtained. Rabbits from 6 weeks to 2½ months old were used. The majority were Belgian hares. Of all the animals coming to necropsy, heart lesions were found in 56.6 per cent. The fact that none of the strains isolated from the blood in cases of endocarditis produced joint lesions, whereas arthritis was present in four cases from strains isolated from the mouth and tonsils seems significant to the writers. It suggests two possibilities: First, that an organism may have in some instances a dual affinity, and depending on environment and conditions existing in the particular individual in which they are present, they may attack one organ or another, or both. Second, that two types were present in one culture and each type produced its respective lesion. Pure cultures only of *Streptococcus viridans* were sought, and on being obtained, no attempt was made to grow the organism from one colony only. The writers venture to suggest that they have established three important points: (1) The *Streptococcus viridans*, isolated from the blood in cases of chronic infectious endocarditis, is of very low virulence, probably lower than any hitherto reported as being recovered from a similar source. (2) These streptococci are capable of producing lesions in animals identical to those found in the patients from whose blood the organisms were obtained. (3) The strains of *Streptococcus viridans* isolated from the mouth of normal individuals are similar to those isolated from the blood of patients suffering from chronic endocarditis, and are equally capable of producing heart lesions in the rabbit.

13. **Development of Herpes Zoster in a Case of Chorea Treated with Autogenous Vaccine.**—Horace Greeley reports the following case: N. H., boy, aged 8 years, in otherwise good general health, had been suffering with chronic twitching of the muscles of the right side of the face for four years. He had had the usual hygienic and tonic treatment with iron, etc. As is usual in such cases, the twitching was almost absent occasionally, as in the morning, and grew worse as the fatigue of the day accumulated; on some days it was almost incessant. Knowing that chorea was closely identified with rheumatism, and that rheumatism, both acute and chronic, had been demonstrated to be due to streptococci, and that, more than most conditions, the beginning chronic form was amenable to vaccine treatment, Greeley determined to try the effect of an autogenous streptococcus vaccine. Accordingly, a vaccine from a tonsillar streptococcus was prepared and given in nine doses at intervals of a week. The first three doses were 200 millions, the fourth 300 millions, and from then on the doses were increased each time 200 millions, until at the ninth dose the patient received 900 millions. On the second and the sixth doses there was a slight constitutional reaction. The herpetic eruption appeared on the day following the second dose and comprised fifteen distinct vesicles, which developed on the skin over and below the extremities of the three lower ribs on the right side. The eruption showed the usual symptoms, and was accompanied by a distinct exacerbation of the chorea lasting for three days. Since chorea is probably due to a low grade streptococcus infection of the connective tissue sheaths of motor nerves, or of some area sufficiently contiguous to them, or to their origin in the central nervous system, to influence their normal functioning, it is easily under-

stood that a focal reaction, following a dose of specific vaccine, would cause exacerbation of symptoms, Greeley is inclined to believe that this is what occurred in this case.

In the case of other than motor nerves, slight central irritation could not be supposed to give rise, ordinarily, to very noticeable manifestations, and it seems probable that such existed in this case, affecting the vasomotor nerves distributed to the herpetic area; and further, that the occurrence of the herpetic eruption involving the terminations of these nerves is best explained as being the result of a specific focal reaction at the points along the nerves presumed to have been the seat of "rheumatic" inflammation.

2. On a Rose-Irrigator for Supplying a Therapeutic Fluid Continuously and at a Standard Temperature to the Whole Surface of a Wound.—Wright, Tanner, and Matson describe this irrigator which apparently fulfils all the requirements demanded of it. As a rose to the body of the irrigator, they employed a rubber cap, and inserted into the perforations a set of tubes. To give stiffness to these rubber tubes and to carry them around corners, a copper wire is inserted into each. Tanner devised the wire arrangement. A drop counter is used to tell the existence of the flow of stream and to regulate the flow, and in the newer arrangement the copper wires are anchored to a rubber bung or piece of stout drainage tube or aluminium ring inserted into the barrel of the drop counter or into the irrigating rose. The irrigator can be made up into three different styles according to type and condition of wound. A thermos bottle into which the rose and tubes can be fitted is used for this purpose as by this means the irrigating fluid can be kept at an even temperature. For prevention or limitation of the escape of fluid in its passage from the irrigator to the wound, thick-walled, narrow-bored rubber tubing is used and the drop counter chamber is made smaller. The flow is regulated by the screw clamp, and the size of the drops by the size of the external diameter of the dropper. The standard size employed by the writers is one of 4 mm. external diameter, obtained by inserting the drawn out glass tube into a hole in the perforated zinc supplied by the hospitals, filing, and breaking off the point at the level of the aperture. In a medium sized wound the flow is adjusted at 90 to 100 drops per minute; larger wounds require greater flow. In order to irrigate the wound and at the same time to keep the bed dry the mattress is cut away from under in the case of a horizontal wound, and a broad strip of jaconet can be passed under the limb and the corners can be looped up and tied round the limb above and below the wound. A type of hammock is thus formed. With this strips of bandage are employed to drain the wound. In wounds in direct position the bandages would be employed as direct drains. In either case they pass out through a hole cut out in the trough of the jaconet hammock and go down into a basin under the bed. When the limb cannot be kept in the horizontal position, or where from the anatomical relations of the wound the jaconet hammock is inapplicable, we can bank back the fluid, and effectually prevent leakage into the bed by "irrigation flanges," built up of cotton-wool covered and fastened down to the skin by strips of bandage soaked in formalin gelatin.

3. The Bacteriology of the Feces in the Diarrhea of Infants.—Logan gives the results of his research in this work as follows: Fourteen cases of diarrhea were all on artificial diet at the time of onset. The flora of artificially fed infants differs from that of breast-fed infants chiefly in a decrease of the acid-tolerant group, an increase of the normal *B. coli* group, and in the appearance of members of the non-lactose-fermenting group along with some increase of cocci. The flora of infants suffering from diarrhea shows similar but more marked changes, and the more severe the diarrhea the more marked the changes. It is possible that the acid-tolerant group exerts a beneficent influence in restraining the growth in the intestine of the non-lactose-fermenting group. Bacilli of the non-lactose-fermenting group were obtained from 6 out of 21 (28.5 per cent.) infants and young children who were free from diarrhea. Bacilli of this group were isolated from 11 out of 14 cases of diarrhea (78.5 per cent). Bacilli of Morgan's No. 1 group were isolated from 9 per cent. of the normal children, and from 35 per cent. of the cases of diarrhea. True, though non-agglutinable, dysentery bacilli were isolated from none of the normal children, but were obtained from three cases of diarrhea with blood and mucus (dysentery), or 21 per cent. of total diarrhea cases. A certain number of cases of diarrhea of infants are therefore true bacillary dysenteries, even in Scotland and in winter time. It is doubtful whether the overgrowth of non-lactose-fermenting bacilli initiates the diarrhea, or whether it is a secondary and aggravating factor.

5. The Origin and Prevention of Cerebrospinal Fever.—Halliday Sutherland states that the *Diplococcus intracellularis meningitidis* of Weichselbaum conforms to Koch's law for pathogenic organisms. Constantly found in the tissues and body fluids of the victims of epidemic cerebrospinal meningitis, the meningococcus may be isolated in pure culture, is able to reproduce the disease in monkeys, can be recovered from the lesions in these animals, and is therefore the causal organism of cerebrospinal fever. At times when the disease is not prevalent meningococci have been found in the throats of 2 per cent. of healthy soldiers. Among healthy naval ratings, not known to have been exposed to infection, Sutherland found meningococci in the throats of two individuals out of a hundred examined, and the organism has been found recently in a larger proportion of the civil population not exposed to infection. The conditions which determine whether or not infection is spread are as follows: Any organism in the nasopharynx may be expelled from the mouth during the act of coughing in small droplets of secretion which float in the air for from half an hour to four hours, according to the density and humidity of the atmosphere. This would easily explain the method of infection provided the temperature of the air was above 22° C., but on the other hand, meningococci soon perish at lower temperatures. Now 22° C. corresponds to 71.6° F., and he found that meningococci die in 30 minutes when exposed to a temperature of 60° F., while lower temperatures are more rapidly fatal. It is therefore clear that air-borne meningococcal infection can only occur in a warm atmosphere, and is impossible in cold air. Epidemics of cerebrospinal fever usually begin in January or February, and disappear with the advent of May. But January and February are the two coldest months of the year. The paradox of a disease which appears during cold weather, but whose specific

cause can only be carried by warm air is explained by the fact that cold weather cuts off means of ventilation and the air indoors becomes warm and saturated. When the disease is spread in summer, the essential condition which determines the secondary invasion of the tissues would be absent. To control the spread of the infection, Sutherland says that all windows and doors must be open day and night. A window ventilator answers the purpose. Pure air is the simplest and surest means of prevention.

1. Remarks on "Pyrexia" or "Trench Fever." John Muir.
2. A Case of Acute Myeloblastic Leucemia. Rowland Hill.
3. Grafting with Frog Skin. H. W. M. Kendall.
4. The Use of Glycerin and Ichthyol in the Treatment of Septic Wounds. Thomas W. A Daman.

1. Remarks on "Pyrexia" or "Trench Fever."—John Muir has based his observations on a twelve months' experience with a field ambulance on the Franco-Belgian front. After stating the symptoms, which by now are well known, he advances the following treatment, which consists mainly of rest and attention to the bowels, which are usually very constipated. Phenacetine, sodium salicylate, and a few other drugs are used to relieve the shin pains. Pyrexia is cut short by the use of two powders, each consisting of morphine acetate gr. ⅛, caffeine citrate gr. 1, phenacetine gr. 8; one given immediately the patient gets to bed and the second two hours later. Attention may be focused on the following points: (1) The nature and mode of conveyance of the infective agent producing the numerous cases of "short fever" met with in our troops are still unknown, and merit further observation and research. (2) The term "trench fever" is distinctly misleading, and is not justified by analysis of the total number of cases which occur in the various units of a division and under varying conditions. Cases occur in considerable numbers in units situated outside the "trench area," and markedly increased incidence is met under suitable conditions whilst the troops are far removed from the trenches. (3) Such inclusive experience can only be gained in a field ambulance, as all cases are primarily brought there, and many (about 45 per cent.) are not transferred to any other medical unit. (4) The name "lice fever" is also objectionable, since it assumes as a fact a possible means of conveyance which at present is merely a hypothesis. (5) The infective agent is probably a widespread virus borne on the persons of men concerned (nasopharyngeal?) normally of low virulence. (6) Incidence of the disease depends upon the condition of the men, whose defense against the infection is specially lowered by exposure and fatigue.

3. Grafting with Frog Skin.—H. W. M. Kendall says that the idea of grafting granulating surfaces with frog skin was put into practice by him as far back as 1886-7 in India. He experimented with satisfactory results to the patients, gratification to himself, and the least possible inconvenience to the frogs. He has obtained the same results in France lately. He reports fourteen cases of successful results. The ideal wound to graft is flat, without much suppuration or excessive protuberant granulations. The rapidity with which the wound commences to heal after the graft has successfully adhered is in marked contrast to its sluggishness before the operation. The wound having been gently cleaned without antiseptics and as gently dried, the loose skin on the inner side of the frog's thigh is carefully pinched up in a pair of dressing forceps, snipped off with scissors, spread out and applied by its under surface to the wound. A strip of gutta-percha tissue smeared with some mild and soft non-irritating emollient is then placed over it, fixed in position at its ends by adhesive plaster, and a dry dressing applied over all. The whole is gently removed in three days, when the site of the graft will be noticed as a purplish spot branching outwards to the periphery of the wound. A similar dressing is again applied for two days to avoid unnecessary interference, after which the wound may be dressed daily, without the gutta-percha tissue, with some simple, non-irritating ointment, such as boracic, until healing is completed. The gap in the skin's continuity is by this process filled up and unsightly or inconvenient contraction avoided.

Bacteriological Diagnosis of Typhoid Fever.—Schmitz, as a result of study of an epidemic in Jena in 1915, reaches the following conclusions: Examination of the stools gave unsatisfactory results; when this method alone was used during the first five weeks of the disease the diagnosis was made in but 11.75 per cent. Of the actual number of tests made only 8.68 per cent. were positive. Better results were obtained by the bacteriological blood test—in 30 per cent. the diagnosis was made. The widal was positive in about 75 per cent. When all the above methods were used in conjunction the diagnosis was made in 91 per cent. In this combined series the bacteriological test gave better results than when used alone. The negative results were probably attributable to unfavorable culture conditions. In regard to the stool test this gave 25 per cent positive results for the first week and then fell off sharply to one-half, finally dwindling to zero. Early tests of blood and feces should give much better general results.

Typhoid Fever and Pneumonia.—Döblin describes some cases. The first was in a robust man who had been vaccinated five times against typhoid. Three months after the last inoculation he was taken ill with diarrhea and subfebrile temperatures. During the course of these symptoms, which persisted for five weeks, he passed through an acute bronchitis, which ran its course in about ten days. In the sixth week the movements became putrid and bloody; thirst and emaciation appeared, and death resulted from asthenia. The autopsy showed typhoid, with lesions most marked in the colon, and perforation. The latter was not clinically apparent, save as scattered pains. In a second patient inoculated three times against typhoid the latter disease set in and pursued its course up to the end of the third week, when a lobar pneumonia set in. After eight days this ended by lysis, the lung cleared up and the typhoid completed its course. A third patient, also three times vaccinated, developed the same association. The pneumonia appeared in the third week and ended by crisis in seven days. In both these cases the pneumonia was a simple complication due to the typhoid bacillus. Even clinically ordinary lobar pneumonia could be excluded. Consolidation appeared and disappeared abruptly and was less intense; there was no true hepatization and bronchial sounds were not characteristic of true pneumonia. There was no dyspnea, cough was not distressing, the sputum not rusty, but decidedly bloody.

Potato Flour as an Addition to Infant Feeding.—Müller does not refer to potato starch, but to a flour made by milling potato flakes. Some time ago maize preparations were used to eke out in infant feeding, but after exhaustion of the supply wheat flour and then "war" flour (wheat and rye) were substituted. The great drawback was the inability of these flours to mix harmoniously with milk. Potato starch when mixed

with milk has a starchy consistency and taste. The author then made use of the milled potato flakes such as have been used as cattle fodder. The potato, after steaming, is laid upon hot rollers and thereby dried and then ground up. When used for fodder the potatoes are not peeled, but for infant nourishment peeling is done by machinery. The mineral matter is not leeched out and in consequence the new product is much better than potato starch for food. The flour is coarse, slightly brownish and of a pleasant taste. Nurslings take it well and it mixes well with milk, making good drinks and porridge. The author hopes to see this product the center of an industry after the war.

Successful Irradiation of Cancer of the Breast in One Sitting.—Friedrich and Krönig first relate some experiences with irradiation of the uterus and ovary and how they have been influenced toward the proper dosage for cancer of the breast. They now declare that the *x*-ray surpasses the knife in the treatment of the latter condition. The erythema dose of the skin has been established as 50 discharges of the electrometer system of the authors' iontoquantimeter. The ovarian dose necessary to bring about amenorrhea in myoma and hemorrhagic metropathies has been established at 10 discharges. The sensibility quotient between the ovarian and cutaneous dose has been fixed at 5. The carcinoma of the breast dose has been fixed at 40 discharges. The sensibility quotient between skin dose and mammary cancer dose is 1.25. Irradiation is contraindicated in the presence of metastases and cachexia. Thus far the authors have not determined the prophylactic dose in respect to recurrence. That *x*-rays can cause the disappearance of certain cancers in one sitting is a well-attested fact. There seems no reason *a priori* why this result cannot be obtained in an operable cancer of the breast. The surgeon has always opposed this course, leaving to the radiographer only the cachectic subject with inoperable growth. These very subjects may become worse under this treatment. The operable breast cancer is easily reached by the rays, much more readily than the cervix uteri. While the authors give us formal histories we get the impression that after a single exposure the breast cancer undergoes involution.

Difficulties in X-Raying the Gastroenterostomized Subject.—Freud claims that a correct *x*-ray diagnosis of potency of a gastroenterostomy is a mere matter of chance. The method now current is quite unsuited for the diagnosis of the presence or absence of a peptic ulcer of the jejunum, because we can neither determine the site of the fistula nor map out the loop of the anastomosis. We obtain no definite idea as to the relation of the latter to the deep point of the greater curvature. Studies of the chemistry and mobility of the stomach throw no light on the situation. We are in need of a method which is not only diagnostic but will also enable us to judge of the suitability of this intervention for the cure of ulcer. The duodenal sound is a valuable accessory in these cases. This instrument will inform us with certainty as to the potency of the anastomosis; will tell us the size of the latter, its site, its relation to the deepest point of the greater curvature, the position of the loop, presence or absence of adhesions, the presence of a sensitive area which might mean a recurrent ulcer. The procedure is as follows: The sound is first introduced to the mark 45 in the usual manner, and the patient then sits or stands while the sound is swallowed under illumination control. As soon as the fistula is entered, the sound is allowed to find its way deeply into the loop until it is arrested; whereupon vomiting movements appear on further swallowing. The olive is now drawn backwards into the stomach and a search made for other possible openings. By means of the sound bismuth contrast masses are conveyed into the anastomosis loop, and the form, capacity, mobility, etc., of the latter brought out. As soon as the contrast substance leaves the loop we should be on the lookout for a bismuth speck which would speak for an ulcer. In like manner we should examine for the presence of a niche above the ring of the fistula. Other important data, notably in reference to sensitive areas, may be obtained by manipulation of the olive.

Journal de Médecine de Bordeaux.

October, 1916.

Waller's Law and the Theory of Trophism. — Pitres after an exhaustive review of this subject announces some conclusions as follows: When any prolongation whatever of any neuron whatever is severed from the mother cell the severed portion undergoes the so-called Wallerian degeneration. This law applies to the peripheral protoneurons with two exceptions which are more apparent than real. First the central segment which in Waller's law remains intact may undergo certain changes (chromatolysis) which may be severe enough to cause the death of the neuron while all its prolongations degenerate. Second, in the midst of the Wallerian degeneration a few fibres habitually remain intact. These are naturally aberrant or recurrent and do not have the same origin as the degenerated fibres. When a motor nerve degenerates the muscles supplied thereby undergo a characteristic degenerative atrophy. The regeneration of a peripheral segment of a divided nerve is brought about by a budding of the central nerve stump (Waller). Regeneration of the fibres of a motor nerve may be followed by regeneration of the fibres of the corresponding muscles. Nervous fibres of the neuraxis, like those of the peripheral nerves, degenerate when separated from their mother cells. Motor fibres degenerate from above downwards; sensory fibres in the reverse direction. The nervous fibres of the neuraxis cannot regenerate after division. Aside from degenerative atrophy of the muscles which results from division of the nerves there is a certain amount of hypotrophy from disuse, so that simple emaciation is found side by side with granulofatty (Wallerian) degeneration of muscle.

Paratyphoid Fever and Bacilluria.—Carles and Marcland state that when the bacteria of an infectious disease appear in the urine there is reason to suspect the presence of a renal lesion. In the majority of cases of typhoid the kidneys remain intact. In bacilluria we find albuminuria and cylindruria. Again, the bacilluria is never limited to the causative germ; staphylococci, for example, often coexist with the latter. A sort of latent cystitis may follow the bacilluria. It is not yet settled whether a paratyphoid bacilluria can occur under the same circumstances, and the author has studied cases from this viewpoint. A patient with an early typhoid syndrome gave a positive blood test (hemoculture) of the paratyphoid A. Later a drop of urine was brought away by a catheter and gave the same positive result. There was also albuminuria. After defervescence there was extensive elimination of urine, which contained only B. coli, the kidneys being intact. A second patient showed mixed infection with Eberth's bacillus and the paratyphus B. As the urine contained blood a test for bacilluria was at first inconclusive, although positive for the para B. After the urine had become clear the latter was still present. The author is not the first to describe paratyphus bacilluria, but prior finds have been conflicting. A prac-

tical point involved is the duration of this form of urinary infection. Cultures cannot always be made from the urine in these cases and the germs may not always be virulent. Attempts to sterilize the urine may fail, and this seems to have been true of the author's second case.

Le Bulletin Médical.

October 28, 1916.

Wounds of the Abdomen.—Quenu considers 180 cases of abdominal wounds as reported in eight separate memoirs on the subject by as many different surgeons. These are analyzed and criticized from his own personal experience. One conclusion stands out clearly—no penetrative wound of the small or large intestine can ever be left for Nature to cure. Lesions of other viscera may benefit from surgical intervention; and in order to determine which viscera are wounded and in what manner, laparotomy is necessary. An exaggerated value is imputed to certain diagnostic elements, such as determination of the trajectory of the projectile, in which radiography is utilized, and this is true of the leading clinical symptoms. These all have value, but are not of critical importance in a rapid summary of indications for operation. In the 180 cases but three needless laparotomies were performed, all of the patients recovering. Is it necessary to operate on every abdominal wound? Evidently not. The upper segment of the abdomen, bounded below by a line which touches both costal arches, may be exempt, although there are numerous exceptions. This exemption is due to the fact that projectile wounds received here may belong rather to the thorax than the abdomen. As for the abdomen as a whole, not every wound indicates an operation. The question is a most delicate one, for if the patient appears to be near death a desperate attempt may be made to save him. On the other hand, if the patient is in extreme shock, an attempt to operate would very likely be fatal. A pulseless patient never benefits by operation. A total absence of pulse, however, must not be confounded with an extremely rapid pulse, which perhaps cannot be counted. Such patients may be snatched from death by operation. A truly pulseless patient must be treated first and every effort made to bring back the arterial tension; while with a patient who still has a pulse no time should be lost in ligating large blood vessels and removing possible causes of sepsis. The technique is comprised under two heads: exploration of the abdomen and treatment of intestinal wounds. The median incision is usually the best. In the exploration the trajectory made by the projectile comes into consideration, and exerts an influence upon the position of the patient. If the pelvic organs are wounded the patient must be in the inclined position. If the anterior wall of the stomach is perforated the back of the viscus must be examined by going through the mesocolon. But, as already stated, the path of the bullet is not to be overvalued as furnishing special indications for treatment. Intestinal wounds demand suture or resection according to the conditions present. In most cases drainage is indicated. In regard to prognosis something depends on the nature of the projectile. The mortality from shell fragments, which was 57 per cent., is much higher than that from fragments of hand grenades (42 per cent). Musket or machine gun bullets are considerably more deadly than shrapnel bullets. Preoperative conditions, which have reference to transportation, and the date of intervention are also powerful factors. Recently operation within three hours has shown a superiority over longer periods. Patients with very little traumatic shock and otherwise in good condition are practically certain to recover after very early intervention. The degree of shock, as Crile has shown, is largely a matter of arterial tension. The low tension of shock is invariably lowered by laparotomy. Vaquez has shown that after ordinary laparotomy, a tension of 140 may be lowered to 100. Long experience has taught the author and his colleagues that operation on a patient with a tension below 100 is inevitably followed by death inside of twelve hours. Below 100 the lower the tension the worse (if possible) the outlook; while the further above 100 the better in theory the outlook—although it should be 120 and upward before we can feel certain of recovery.

The New French Decree Against the Sale of Poisons.—An outline of the provisions of the decree of September 19, 1916, is begun in the current number of the *Bulletin*. The old decree had been in existence since 1846. The successor refers to three separate categories of poisonous drugs. In the first category, represented by Table A, we find toxic substances in the ordinary sense of the term. The author enumerates only those which are used in medicine, and the list includes all the most violent poisons, such as aconitine and cyanides. In the second category, as shown in Table B, are to be found the various habit forming drugs, which are relatively few in number. Unusual restrictions and severe penalties are attendant upon the traffic in these substances. The third category comprises drugs which are known simply as dangerous and corresponds to Table III. The present installment in the *Bulletin* deals only with Table A. One notes with some surprise that codeine, laudanum, and the tincture of opium of the French Codex are retained in Table A, along with certain substances of low toxicity. Apparent contradictions in the tables are accounted for by the special provisions of the decree. All drugs in Table A may be supplied by pharmacists, physicians, and veterinarians, by the former, however, only on prescription from the two latter. Dentists and midwives may furnish their patients with substances from a special list, upon prescription also. Renewals may be dispensed unless the writer of the prescription expressly forbids it. There are special restrictions in connection with prescribing powerful poisons by the mouth and by hypodermic, consisting in limiting the twenty-four hour dose. If the figures are exceeded the pharmacist must not fill the prescription. Those calling for laudanum can be renewed only under special provisions. Certain limitations pre-exist in the Codex, which may therefore be used as a guide in certain renewals. Thus the maximum amount of arsenic to be ingested in twenty-four hours is stated therein. There is, however, a "joker" in the new decree which states that a new prescription is to take the place of a renewal, *i.e.*, the old prescription is given a new number. It is not considered necessary for the pharmacist to record the name of the purchaser, as the maker of the prescription, with date, etc., and special number are held to be sufficient. The article will be continued.

Fistula in Ano.—Göz has studied ninety-five cases of this affection in the Munich Surgical Clinic. In 43 per cent. tuberculosis was in evidence as a factor. Division of the sphincter caused incontinence only when several times repeated. The rule is therefore to divide but once. Single incision with the thermocautery will cure 67 per cent. of those treated, while repeated incisions give only 14 per cent of cure. The presence of tuberculosis aggravates the prognosis.—*Inaugural Dissertation, Tübingen*, 1916.

Insurance Medicine.

The Consideration of Rectal and Colonic Diseases in Life Insurance Examinations.—Alfred J. Zobel states that all important data concerning the vital organs are obtained by a medical life insurance examiner by direct examination and by precise methods; but, on the other hand, life insurance companies evidently do not attach much importance to the condition of the rectum and colon—not to mention the rest of the alimentary canal—for they seem willing to assume that these organs are free from disease solely from the favorable answers given by the applicant to routine printed questions asked by the examiner. That this is a fallacy, inasmuch as it paves the way to the acceptance of poor risks, and occasionally to the rejection of a good one, he demonstrates in his paper. Applicants almost invariably deny having or ever having had rectal or colonic diseases.

The writer says that the individual knows little about his anorectal region, and unless there is severe pain or itching, alarming bleeding, or annoying dysentery, he thinks it of little importance and unworthy of the attention of either himself or the examiner. The rectal surgeon often sees individuals who look and feel in the best of health (outside of "a little attack of pile"), yet who are found victims of well advanced malignant disease of the colon or rectum. Unless a rectal examination be made such a person could easily pass a life insurance examination. The examiner should look out for those little fistulous tracts which cause no pain and discharge but little secretion, as they are frequently the primary manifestations of tuberculosis, and may appear in those who are otherwise healthy. A severe stricture of the rectum may be present in a man outwardly perfectly healthy and insurable. If a history of hemorrhoids is secured, or if they are found on examination, it should not be forgotten that although their existence does not constitute a good cause for rejection, they often accompany liver, spinal cord, genitourinary, and uterine diseases.

If a rectal examination is made the condition of the genitourinary organs in the male can be investigated, while in the female accurate information can be obtained about the pelvic organs without subjecting them to a vaginal examination. At present only information as given by the woman applicant as to the condition of her pelvic organs is demanded by the insurance companies. In conclusion Zobel offers the suggestion that medical examiners should lay more stress upon the questions regarding the condition of the bowel and rectum. A history of discharge, chronic constipation or of diarrhea should be worthy of further investigation, and, if there is need, a rectal examination should be made. That medical examiner is most efficient who not only secures his company from poor risks but also saves it business which otherwise would be lost, and the employment, in all suspicious cases, of a rectal examination helps attain efficiency.—*Journal of the South Carolina Medical Association.*

Diseases of the Ductless Glands and Internal Secretions in Relation to Obesity.—In a paper read before the Assurance Medical Society in London, England, on January 5, 1916, Dr. F. Parkes Webber spoke of the diseases of the ductless glands and internal secretions in relation to obesity. The chief syndromes associated with excess of fat, he said, are Dercum's disease, diffuse symmetrical lipomatosis of the neck and other regions, and Fröhlich's pituitary syndrome of adiposity with insufficiencies of the sexual organs, with which may probably be allied most cases of "eunuchoid" obesity in men. A condition which might be legitimately described as "precocious obesity" has been occasionally observed in children in association with new growths of the type of malignant hypernephroma. A condition of lymphatism associated with excess of subcutaneous fat might perhaps likewise be included under this heading. W. Ebstein has divided ordinary obesity into three stages, viz., the enviable stage, the comic stage, and the pitiable stage. It is in the third stage, the pitiable or helpless stage, that the wretched person loses bodily strength and activity, cannot take exercise, and has no longer the will power to resist his complaint. It is in the first stage, that is the stage of plumpness or embonpoint, the stage admired by many, that strict moderation in eating and drinking ought to become a habit. Webber is quite sure that if the relatively early stages of obesity were more generally regarded in a serious light by life assurance companies, if slight extra ratings were more generally insisted on, and if that became universally known to the lay public, many more candidates for the righer grades of obesity would be inclined to alter their manner of living in time to avoid arriving at the helpless stage. Of course, it is not directly from their obesity that most fat persons die, but from the complications of obesity or the diseases associated with it.

Albuminuria and Life Insurance.—It seems scarcely credible that a symptom which is common to so many diverse conditions, both physiological and pathological, should so long have succeeded in masquerading as necessarily connoting renal disease. And yet it is within the experience of all of us that people have been, and, alas! are still being, refused for life assurance and otherwise condemned as damaged individuals merely because, from some of the above-mentioned causes, a little albumin has been found in their urine. It would be just as logical—it would, indeed, be more reasonable—if dyspnea were regarded as necessarily indicating pulmonary or cardiac disease. Dyspnea is in many cases very significant of such disease, but inasmuch as we have all of us become very breathless hundreds of times in the course of our lives, without any untoward effects, we have acquired some sense of perspective in the matter. It would be a good thing if the presence of albumin in the urine could be manifested by some sign equally gross and obtrusive. We should then come to realize how frequent an occurrence it is, and how seldom it really indicates anything more serious than a mere passing change of pressure in the blood vessels of the splanchnic area.—*Medical Press and Circular.*

Hernia in the Light of an Accident.—Loss of time due to an operation to relieve a hernia caused by a fall is held covered in the Iowa case of Berry v. United Commercial Travelers, L.R.A.1916B, 617, by a policy of accident insurance against loss of time on account of bodily injury effected through external, violent, and accidental means, although the policy provides that the payments authorized shall not cover loss resulting from or in consequence of hernia.

Book Reviews.

Diseases of Occupation and Vocational Hygiene. Edited by George M. Kober, M.D., LL.D., and William C. Hanson, M.D. Price, $8 net. Philadelphia: P. Blakiston's Son & Co., 1916.

Nothing is more significant of the present trend of preventive medicine than the appearance at this time of so ambitious a work on this subject. Composed, as it is, of the articles of some thirty contributors, each specially expert in his own subject, it offers the most complete production of its kind which has yet appeared. The interest in this topic has been growing rapidly in this country in the past few years, and its progress has been hastened by the passage of various workmen's compensation acts. The passage of health insurance laws, which may be looked for in the near future, will only strengthen the stimulus which now urges the employer to throw every possible safeguard about the life and health of his employees. A branch of medicine which is showing such intense activity demands a textbook which is prepared with great care and breadth of view and exceptional completeness. Such a book is found in the volume under discussion. Practically every possibility of disease of occupation is considered, and the means of prophylaxis pointed out. In addition there is a large section on governmental study and legislation and a short chapter on statistics which is deserving of special attention.

University of Iowa Monographs. Studies in Medicine. Prof. Henry Albert, Editor. Volume I, Number 1. Iowa City, Iowa: Published by the University, June, 1916.

This monograph is made up of ten reprints of articles which have appeared in widely read medical journals during 1915-16, with a single non-medical exception. The articles are almost all of high class; but as the reading physician or surgeon will have already read them, it is unnecessary to make a recapitulation. Taken as a whole, they speak well for the activities of the University.

A Practical Medical Dictionary of Words Used in Medicine with their Derivation and Pronunciation, Including Dental, Veterinary, Chemical, Botanical, Electrical, Life Insurance and other Special Terms; Anatomical Tables of the Titles in General Use and those Sanctioned by the Basle Anatomical Convention; Pharmaceutical Preparations, Official in the United States and British Pharmacopœias and Contained in the National Formulary; Chemical and Therapeutic Information as to Mineral Springs of America; and Comprehensive List of Synonyms. By Thomas Lathrop Stedman, A.M., M.D., Editor of "Twentieth Century Practice of Medicine," of the "Reference Handbook of the Medical Sciences," and of the Medical Record. Fourth Revised Edition. Illustrated. Price, $5 net. New York: William Wood & Company, 1916.

It will be superfluous to say much regarding a dictionary which has gone through four editions and which is consequently so well known to the profession as is Stedman's medical dictionary. Whatever sins of commission or omission have been perpetrated in former editions, they have not been committed or omitted in this edition. That is to say, that the author has benefited by intelligent criticism, and that the revision has been thorough. Medical terms and titles are coined with such rapidity that it is difficult for a dictionary to keep pace with them. For example, in this issue no fewer than 2,000 new words have been added, the majority of which have been born in the last two years. In this edition, too, all the terms of the Basle Anatomical Nomenclature are indicated even when they do not differ from the vernacular. Like the former editions this one is an excellent specimen of the publishers' care and of the printers' and binders' art.

La Fièvre Typhoïde et les Fièvres Paratyphoïdes (Symptomatologie, Étiologie, Prophylaxis). Par H. Vincent, Médecin-Inspecteur de l'Armée, et L. Muratet, Chef des Travaux à la Faculté de Médecine de Bordeaux. Prix 4 fr. Paris: Masson et Cie., 1916.

This book is one of the first numbers of a series of epitomes of war medicine and surgery which is being issued at the present time. The volumes are light and of convenient size and are designed for the use of medical officers on active service. They are admirably adapted to this purpose, if this volume is any criterion, and should find a wide acceptance. This book on typhoid and paratyphoid fevers contains in very condensed form practically all our present information on the subject. The first part has to do with the etiology, symptomatology, diagnosis, and treatment, while in the second part is an extensive discussion of the epidemiology and prophylaxis. There is no attempt to discuss the pathology of these diseases. The authors apparently have more faith in the value of the diazo reaction than is generally found in this country, and have had much success with the use of vaccines as a form of treatment. It is on the whole a very excellent presentation of the subject and valuable at this time, when medical men are beginning to realize that paratyphoid fever is much more common than has hitherto been supposed.

Localization by *X*-Rays and Stereoscopy. By Sir James Mackenzie Davidson, M.B., C.M., Aberd., Consulting Medical Officer, Roentgen Ray Department, Royal London Ophthalmic Hospital, and *x*-Ray Department, Charing Cross Hospital; Fellow, Physical Society; President, Radiology Section, Seventeenth International Congress of Medicine. Price, $3. New York: Paul B. Hoeber, 1916.

This book is a personal one, the results of 20 years' experience, including, of course, the finds of two years of warfare on a huge scale. It is based wholly on work with the older tubes. The Coolidge tube is briefly mentioned and the author is silent on the other gasless tubes. There are but 70 pages of text, with nearly as many illustrations, 35 being stereoscopic plates. Such a book can hardly be given an analytical review, but should be of great interest to all radiologists.

Les Séquelles Ostéoarticuliculaires des Plaies de Guerre. Par A. Broca. Price, 4 francs. Paris: Masson & Cie., Editeurs, 1916.

This volume is one of a large series of small monographs, the outgrowth of the present war. They are doubtless meant to serve the surgeon at the front and at the same time to form a document of the lessons of the war after the latter has expired. The author has recently published a beautiful work on amputations and excisions, noticed at the time in these columns, and the present manual deals with such subjects as vicious callus, traumatic osteomyelitis, ankyloses, and the question of pensions. From the nature of the 112 illustrations it appears that the work belongs largely under surgical pathology.

Principles of Diagnosis and Treatment in Heart Affections. By Sir James Mackenzie, M.D., F.R.S., F.R.C.P., LL.D., Ab. & Ed., F.R.C.P.I. (Hon.), Physician to the London Hospital (in charge of the Cardiac Department), Consulting Physician to the Victoria Hospital, Burnley. Price, $2.50. London: Henry Froude; Hodder and Stoughton; New York: Oxford University Press, American Branch, 1916.

Any book on the heart from the pen of Sir James Mackenzie is sure to be welcomed, for not only is what he says authoritative, but it is said in such a way as to hold the attention of the reader and combine for him pleasure with study. The present work was prepared for a post-graduate lecture course at the Cardiac Department of the London Hospital, but the war prevented its delivery. No change was made in the form of presentation, when publication was decided upon, except to divide the book into chapters; the style is therefore colloquial—which is an advantage rather than a drawback. The book is one for the general practitioner rather than the heart specialist or the laboratory experimentalist, and only cursory mention is made of such expensive and usually unnecessary apparatus as the electrocardiagraph. The reader who has been brought up to believe in the many and great dangers of disease of the heart will receive frequent shocks in coming across such statements as that the author has never seen the so-called "athlete's heart" which he characterizes as an absurd bogey, and that dilatation can never be produced in a healthy heart as a result of overstrain; he also warns against Nauheim "and all other forms of cure over which there is a trail of commercialism"; he speaks slightingly of the value of blood pressure estimations in diagnosis, prognosis, or as a guide to treatment and doubts whether we shall ever find them of any considerable help in our work; and his scepticism as to the utility of a few protein or purin free diet is patent. With all due respect to this acknowledged authority on cardiac diseases, we regard him as a safer guide in the diagnosis than in the treatment of these affections.

Society Reports.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Forty-second Annual Meeting, Held at Indianapolis, Ind., October 10, 11, *and* 12, 1916.

THE PRESIDENT, DR. WILLARD J. STONE OF TOLEDO, OHIO, IN THE CHAIR.

(*Continued from page* 1054.)

Blood Chemical Analyses in Reference to Diagnosis and Treatment.—Dr. R. B. H. GRADWOHL of St. Louis said that chronic kidney degeneration was accompanied by the accumulation of all three constituents—uric acid, urea nitrogen and creatinin. The normal finding in respect to uric acid was 1 to 2, 5 milligrams per 100 c. c. of blood; of urea nitrogen, from 12 to 15 milligrams, and of creatinin of from 1 to 2.5 milligrams. An undue accumulation of all three constituents was a remarkably valuable method of estimation of true kidney function. Values for urea nitrogen in conditions of uremic nephritis had been known to reach as high as 300 milligrams, and of creatinin as much as 30 milligrams. These high values indicated grave uremia. His experience had shown the tremendous accumulation of these constituents in bad cases of nephritis, even where the urinary findings were scant so far as albumin and casts were concerned. He had been able in all his work to confirm the contention of Myers and Lough that the presence of over 5 milligrams of creatinin in 10 c. c. of blood indicated an absolutely fatal prognosis. The combination of nephritis with diabetes mellitus had possibly long been recognized, but too often was disregarded. The estimation of blood sugar in diabetes should be accompanied by an estimation of the other non-protein nitrogenous blood constituents to determine the condition of the kidney. If blood chemical analyses were made more often in grave diabetic states it would be shown that some of these so-called cases of diabetic coma were really in a state of extreme uremia due to this complicating nephritis. Many cases of diabetes mellitus had died of uremia and were called diabetic coma and treated as such. By personal experience he was able to confirm the data already obtained on the undue accumulation of these non-protein nitrogenous constituents of blood in gout, the nephritides and deranged renal conditions. He had used the blood sugar methods of Benedict and Lewis and could vouch for their inestimable benefits in the diagnosis and treatment of diabetes mellitus. He could also recommend the Van Slyke method of estimation of the combining power of blood plasma. Another field of usefulness of these tests which was now opening up was the preoperative survey of surgical cases, the estimation of operation risks, and the manner in which kidneys were functionating after operative interference. This should prove of great help to the operating surgeon.

The Clinical Value and Methods of Blood Analyses in Medical Diagnosis.—Dr. G. W. MCCASKEY of Fort Wayne first asked attention very briefly to the subject of acidosis as determined by dialysis, removal of carbonic acid from the dialysate by aeration and the determination of the hydrogen ion content by the indicator method according to the technic of Merriott. The determination of the hydrogen ion concentration of the fresh blood containing as it did variable amounts of CO_2, did not give us any definite information in regard to the actual existence of acidosis. The existence of acidosis could only be assumed when there was a diminution of the reserve alkali of the blood which was made up of the bicarbonates, alkaline protein compounds and alkali phosphates. Under normal conditions this reserve was very constant. The total hydrogen ion concentration might be constant with varying amounts of reserve alkali by fluctuation of the CO_2 content. A certain very slight degree of acidosis, almost infinitesimal in amount, was physiologically required for stimulation of the respiratory centers, and this was really the information given by determining the total hydrogen ion concentration of perfectly fresh blood. This had, at present, very little clinical value. If, however, we dialyzed the oxalated blood, or perhaps, better still, the serum and completely removed the CO_2 by aeration, the hydrogen ion concentration then became a very accurate measure of the alkali reserve and varying grades of acidosis might be accurately determined. It was no longer necessary to make a clinical guess as to the existence of an acidosis. A normal alkali reserve under average conditions of diet was found to vary but little and was expressed by the logarithm 8.5 with a variation of 8.4 up to 8.55. These various grades of acidosis in adults were found especially in diabetes and in some cases of nephritis, but of course they were much more common in children in which the tendency to acidosis was much more marked. It was largely a question of the quantity of acid products of metabolism and whether they were volatile like carbonic acid or non-volatile like oxybutyric, sulphuric, etc. The latter acids actually combined with the reserve alkali of the blood permanently fixing it, producing genuine and demonstrable acidosis with the symptoms of which we had long been familiar. The sugar content of the blood had a very definite clinical significance. Under physiologic conditions it was 0.1 per cent. or less. This was the threshold beyond which renal excretion occurred with normal kidneys. With a rise in this threshold considerably above 0.1 per cent., which occurred in some cases of diabetes and nephritis, the quantity of sugar in the blood might be greatly increased, producing tissue irritation and various functional perversions, but without glycosuria. Hence the importance of estimating the sugar content of the blood in all doubtful cases. In addition to the determinations of the alkali reserve and sugar of the blood, and perhaps, more important than either, the estimation of the creatinin, urea and uric acid content of the blood demanded our attention. Creatinin, the determination of which in the blood had just been outlined, was first given clinical significance by Folin as the most constant exponent of nitrogen tissue metabolism. Recently Lyers had studied its blood retention in nephritis. A considerable increase undoubtedly occurred in the severer grades of nephritis, but in the quantities usually present it was so easily excreted by the kidneys that its retention undoubtedly marked severe impairment of the kidney function. His own observation led him to conclude that the quantity normally present was nearly always less than one milligram per 100 c. c. of blood. Six mgm. had been his most common result. In seven fatal cases of nephritis and a considerable number of non-fatal cases he had never found the very high values reported by Myers. As a result of his own clinical studies he was forced to conclude that 1.5 to 2 mgms. of creatinin per 100 c. c. of blood indicated pathological retentions from increased renal block. The quantity of urea in the blood, as was well known, was influenced within certain pretty well defined limits, by the proteid intake. Widal's estimate was 20 mgms. per 100 c. c. in health. It undoubtedly varied both ways from this amount, but on ordinary diet, 30 to 35 milligrams might be regarded as the highest normal limit. Recent studies by Chase and Myers seemed to indicate that in variations of the uric acid content of the blood we had an earlier and more delicate index of impairment of renal function. Of the three principal end products of metabolism there was apparently more difficulty in excretion, and comparatively slight impairment in the functional capacity of the kidneys led to an increased quantity remaining in the blood. The estimation of the chlorides in the blood did not seem to hold out as much promise as in the case of the nitrogenous constituents and sugar. The chlorides apparently had a habit of playing hide and seek between the tissues and the blood, influenced by physiological and pathological conditions which were at present obscure.

DR. H. K. LANGDON of Indianapolis stated that body metabolism in general found expression in the urine in some manner, but this expression was frequently only an end reaction, and was subject to great variation, due not only to the complexity of kidney function, but also to many extrarenal factors. It was reasonable to suppose that the blood would give us a more intimate knowledge of the changes in metabolism brought about by certain internal diseases. The phenolsulphonephthalein test, as it was most generally interpreted, was a test for the entire eliminative power of the kidney as a whole, but the kidney was a very complex machine and the physiological functions of the component parts were affected in different degrees by different diseased conditions. It was not right, therefore, to place too much dependence on this one test, or any one test for kidney function, or upon one test for any obscure condition. This tendency was well illustrated by the attitude of many medical men towards the Wassermann test for syphilis. It seemed to be the general idea that a blood Wassermann was

sufficient, when the collected data up to the present time showed that the examination of the spinal fluid was of greater value than the blood Wassermann, not only in late but in early syphilis. Ambard's coefficient had a precise expression of the elimination of urea by the kidney for ordinary clinical purposes, was probably not as accurate or as practical as the estimation of blood urea. McClean had modified Ambard's calculation in an effort to simplify it and to make the quotient rise and fall with kidney efficiency. This method had its place in selected cases. In a series of cases he used Bertrand's method of blood sugar estimation, but titration against a standard solution of potassium permanganate did not give a well defined end point, and he found his results very unreliable. The method of Benedict and Lewis was much more accurate.

Dr. G. W. McCaskey of Fort Wayne stated that the advantage of the Marriott method was this: Recently he had a case in the hospital that he thought showed some intoxication acidosis. His assistant and he went to the hospital with a little collodion sac and a test tube in the vest pocket. They drew the blood and had a little saline diluting solution put in the collodion sac and dropped it into the solution. This must be done immediately in order to get the first reading when the CO_2 was present. While they were doing something else they took the blood out and threw the sac away. The reading was 7.6. They then went to the office with the test tube in their vest pocket, took a bulb with a capillary pipette and blew air through this for three minutes, and in that time it had lost a little carbonic acid while going to the office, a distance of several squares. But while pumping this air through for three minutes it changed from 7.6 to 8.6, the very highest limit. So that if anything the patient had a hyperalkalinity rather than an acidosis. This was an illustration of the rapidity and ease with which this could be used. In regard to the high limit of creatinin in fatal cases of nephritis, he had seen a patient die of typical nephritis with a phthalein estimate of only 2.5 milligrams creatinin per c. c. He had seen that happen. It was undoubtedly an exception.

Fractures of the Hip.—Dr. P. M. Hickey of Detroit said that in considering the practical benefit to be derived from roentgen studies, such as were presented in the paper, he would feel that its importance primarily lay in the establishment of an accurate diagnosis. The mechanics of fractures had not assumed its proper place. While the cardinal symptoms of fracture—first, disability, and second, localized area of tenderness—might serve to establish the presence or absence of a fracture, still the question of the treatment would of necessity be based largely on an accurate recognition of the type of fracture and the position of the broken parts. If the roentgenogram told us exactly the part of the bone which was broken, and our knowledge of antaomy told us which way the fragments were displaced by muscular pull, the art of the surgeon would be much helped in solving the problem of proper measures for the mechanical reposition and retention of the displaced fragments.

Diagnosis and Operative Treatment of Vesical Diverticula.—Dr. Filipp Kreissel of Chicago stated that diverticula of any appreciable size and situated close to the lower part of the ureter would eventually displace the same or by pressure give rise to dilatation of the renal pelvis, resulting in hydronephrosis, eventually atrophy of the parenchyma, and if infection should supervene pyelitis, pyelonephritis and kidney abscess. Rupture of the overdistended sac, extra or intraperitoneally, with serious or fatal consequences had also been recorded. Since it was of more importance to ascertain the presence of a diverticulum than to settle the question whether all or some were congenital or secondary, a consideration of the gravity of these lesions should make an early diagnosis imperative and early treatment desirable. By an early recognition of the anomaly most, if not all, of the enumerated complications might be prevented and the opportunity given to render a radical operation more simple before infection and inflammation had resulted in dense adhesions between the sac and important pelvic and abdominal structures. Furthermore, better functional results might be expected from an early operation, since the breaking down of dense or extensive adhesions was always followed by the formation of new, unyielding tissue which interfered with the free mobility of the bladder wall. In the early stage frequent and fractionary urination should at least arouse suspicion, but we would not be justified in diagnosing a diverticulum from this one point alone since pollakiuria was also a symptom of lesions of spinal or cerebral origin. With conservative and palliative operative procedures, such as drainage of the sac, enlarging the diverticular opening, curetting or cauterizing its wall, nothing could be accomplished. Better and more lasting results would follow radical surgery of the sac. The available records of the reported cases clearly proved this contention. In all the radical operations, about twenty altogether, including two of his own cases, there were three cases of death, one due to sepsis after a transperitoneal operation, and two which occurred some time after the operation and were due to secondary advanced lesions in the corresponding kidney. In the other cases the results were highly satisfactory, some being completely relieved from all symptoms, others retaining the tendency of voiding in several phases.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, Held November 2, 1916.

The President, Dr. Walter B. James, in the Chair.

This meeting was arranged with the cooperation of the Section on Genitourinary Diseases.

The Relation of Chronic Infections of the Genitourinary Tract to Obscure Internal Disorders.—Dr. Hugh Hampton Young of Baltimore presented this communication, in which he stated that this subject of focal infection was one of great importance, but he realized that it would be difficult to bring together accurate comprehensive data to show the important rôle played by the genitourinary tract. He briefly reviewed some of the more salient features of the literature on this subject and said the first question that came up was "What are the 'obscure internal disorders' which are related to focal infections?" Billings gave a rather terrifying list in recent publications which included acute rheumatism, arthritis deformans, gonorrheal arthritis, malignant endocarditis, myositis, myocarditis, septicemia, nephritis, various visceral degenerations, thyroiditis, pancreatitis, peptic, gastric, and duodenal ulcer, cholecystitis, various cardiovascular degenerations, arteriosclerosis, and chronic neuritis. Wright had added the following: Secondary anemia, urticaria, furunculosis, eczema, diabetes, purpura hemorrhagica, asthma, chronic catarrh, and nervous breakdown, and Maier cited cases of anorexia, tachycardia, and asthenia, as due to chronic infections. McCrae, giving cases seen in the writer's clinic, laid stress on the disproportionate general symptoms which accompanied lesions of the verumontanum, prostate, and seminal vesicles. In 1906 they (Young, Geraghty, and Stevens) called attention to various obscure referred pains which occurred as a result of chronic inflammatory infiltrations in and about the prostate, ejaculatory ducts, and seminal vesicles. Previous diagnoses of lumbago, renal and intestinal colic, neuralgia, neuritis, and sciatica had been made, but were dissipated by the cure of the prostatic disease. Dr. Young then took up seriatum the various genitourinary regions subject to infection, and pointed out the anatomical peculiarities which might render certain locations natural points for the localization and persistence of infectious processes. A glance at the anatomy and pathology of the kidney would seem to indicate at once that many opportunities for absorption from localized infectious processes were present. In the glomerulus was found a distended sac with constricted neck and uphill drainage, and likewise in the urinary tubule imperfect drainage in the narrow ascending tubule should infection occur. In parenchymatous and perinephritic infections the chances of absorption and resultant general sepsis were even greater. From the renal pelvis and calyces the drainage was ordinarily good and in simple pyelitis little absorption was seen, but inflammatory infiltrations, anatomical abnormalities, and calculus interfered with drainage in many cases and pelvic dilatation, hydronephrosis, destruction of renal cortex, and perirenal inflammation followed, producing typical conditions for systemic invasion with toxins and bacteria. One should therefore expect to find in our clinical material and in the literature an abundance of evidence of systemic disease from focal infections in the kidney and pelvis. But strange to say such was not the case. Rheumatism and arthritis were certainly very rare as a complication, their own clinical

records showing nine, and a hurried survey of 4000 autopsy records revealed no case with a combination of arthritis and chronic renal suppuration. Many instances, however, of chronic myocarditis and occasionally of endocarditis were found. A careful search of the literature revealed very little information on this subject. Billings said "pyelitis of whatever type, even when there is only moderate obstruction of the drainage of the kidney pelvis, may produce myositis, arthritis, neuritis, etc.," but he gave nothing more on the subject and cited no case histories. Other writers and also the more recent text-books on pathology, bacteriology, and surgery threw no light on the subject. All investigators were agreed that streptococci were very rarely found in chronic urinary infections (cystitis and pyelitis) and this might explain why arthritis, rheumatism, and endocarditis so rarely accompanied renal suppurations; apparently the latter were specifically due to streptococci and gonococci, both of which were found with great rarity in focal renal infections. In the acute suppurative nephritis of Brewer the foci of infection of which were generally due to the staphylococcus, endocarditis often existed, but both were acute local manifestations of a blood infection and did not properly belong to the subject under discussion. Changes similar to those in the upper end of the ureter which led to urinary obstruction, pyelitis, nephritis, etc., might exist almost anywhere along the course of the ureter with similar results. A review of the statistics of cultures from 800 cases of metastatic arthritis studied by Murphy and Kreuscher, and recently presented here, again furnished conclusive evidence that arthritis was a coccus disease. Their demonstration that the disease was periarticular confirmed other work in which the joint fluid had been usually found sterile. The terminal portion of the ureter was frequently obstructed by calculi, strictures, tumors, and congenital defects, and so one often found it transformed into a dilated flabby tube filled with stagnant infected urine, surely propitious for producing back-pressure effects and general toxemias. Here again the literature and clinical material afforded little help, no citations of definite systemic infections being given which could be attributed to pyoureters being found. It was not to be expected that much absorption would occur from ordinary cases of cystitis. Sometimes the mucous membrane of the bladder was so resistant that an infection might persist for months without causing inflammation. When obstruction was present however, drainage was interfered with, residual urine developed, the bladder became trabeculated, pouches and diverticula formed, and excellent opportunities for infection, deep-seated inflammation, ulceration, septic absorption, and general infection occurred. Here again the absence of streptococci was probably the reason one rarely encountered rheumatism or arthritic complications. But the bacilli of the colon group which preponderated here as the infective agent were far from harmless. The course followed by the *B. coli* infections of the bladder were seen regularly in enlarged prostate cases. After a few catheterizations the bacilli were generally found in the urine, and after a time, as a rule, a mild cystitis and urethritis resulted with varying systemic manifestations—fever, malaise, and occasionally chill and evidence of severe toxemia. After a short period — three to ten days — a tolerance for the chronic infection was established and the patient might go on catheterizing himself for the rest of his days with only occasional attacks of sepsis. If, however, regular catheterization was not afforded and considerable residual urine was persistently present, the pressure effects produced results of a serious nature upon the whole organism. Just as the bacilli got into the circulation from the intestinal tract when the latter was in a condition of stasis due to chronic constipation, so might the same organisms infect and poison the body in chronic urinary obstruction. A more potent effect was probably produced upon the kidneys and through them the heart, blood vessels, and other vital structures by infection combined with back pressure. The clinical picture was a common one: a pale anemic, asthenic patient, with lack of appetite, at times nausea and severe digestive disturbances, and with evidence of myocarditis, arteriosclerosis, hypertension, and chronic renal insufficiency. The catheter showed residual urine of poor quality, the phthalein test revealed marked impairment of the kidney function, and uremic and cardiac crises during the course of palliative treatment emphasized clearly the desperate condition of the patient. Such cases not infrequently showed little or no urinary symptoms, and went along untreated for months or years, the patient being treated for the above-mentioned conditions, while the back-pressure and colon-bacillus infection went merrily on. The proof of the urological etiology of these grave internal disorders was the way in which they disappeared when the back pressure of infected urine was relieved by systematic catheterization, drainage, or prostatectomy. Distinguished internists who had directed the treatment of certain severe cases, had been astounded to see patients who were apparently *in extremis* gradually become rational as uremia disappeared and vascular, myocardial, and endocardial conditions improved so astonishingly that ultimately a radical perineal prostatectomy was carried out almost without risk. The remarkable recuperative power of the kidneys was shown by the scores of cases in which the phthalein test and blood urea indicated that only a trace of functional capacity was left on entrance to the hospital, but which under catheter drainage so rapidly improved that often within a month a fairly normal function was obtained and operation successfully performed. Coming to the urethra it was found that the various glandular structures surrounding and draining into the urethra, all with narrow ducts, furnished a most fertile field for the development of chronic infections. This was the most complex glandular system in the body, and as one or all of these structures were infected in thousands of cases of gonorrhea one could appreciate the dangerous status of these patients not only to society but also to themselves. The medical profession was even yet rather ignorant or indifferent to the fact that the patient should never be declared cured of his gonorrhea simply because the discharge had ceased and shreds were no longer present in the urine. The examination of the secretion from the prostate and seminal vesicles was so easy and so decisive that it should never be neglected before discharging an acute or chronic gonorrheal case as cured. The remote lesions caused by the extension of a gonococcus infection were manifold. Almost every tissue and structure of the body had yielded its cases of gonococcus infection. Although fulminating in onset many of these very severe infections, even endocarditis and general septicemia, were sometimes not fatal, but the deforming effects were generally terrible in their results. One of the most interesting phases of chronic gonorrheal inflammation was the general disappearance of the gonococcus and its frequent supplacement by other bacteria, particularly the streptococcus. This had been particularly demonstrated in chronic seminal vesiculitis. It had been shown that the gonococcus disappeared with increasing rapidity as the years went by. In a bacteriological study of chronic prostatitis the writer and his associates (Geraghty and Stevens) found the streptococcus present in 16 per cent. of the cases, *Staphylococcus albus*, in 16 per cent.; no colon bacilli and no gonococci were found in any case, though 50 per cent. came within three years of the gonorrheal infection. There was apparently definite proof that the pyogenic cocci and not the gonococcus or colon bacillus was responsible for chronic infections of the prostate and seminal vesicles, and also for the arthritis and rheumatic conditions which so frequently accompanied them. Clinical cases in great numbers were on record to prove the varied lesions remote and serious in character which owed their existence to infection of the seminal vesicles and probably also to infections of the prostate and other adnexa. From the experiments of Thaon, Posner, Kohn, Comus, and Gley, Leguen, and Gaillardot there seemed to be little doubt that the prostate had an internal secretion. The active principle had not been isolated nor its exact physiological properties established, but evidence pointed to its being toxic when injected into animals and that it affected the blood pressure and to some extent the heart. Certain investigators had noticed an anticoagulative action, and this might be responsible for some of the rather troublesome hemorrhages that sometimes occurred from the prostate. Not infrequently the prostate was seriously inflamed in conjunction with the seminal vesicle, and it might be responsible alone for remote rheumatic and cardiac lesions. It should unquestionably be incised and drained along with the seminal vesicle in such cases. Likewise infection often occurred in hypertrophy of the prostate, invading, as a rule, the normal layer of prostatic tissue behind and external to the hypertrophied lobes. Several of the writer's cases associated with joint and heart disorders had rapidly improved after perineal prostatectomy in which this portion of the prostate was drained by the preliminary capsular incision. In some prostatectomies he had exposed and

drained the seminal vesicles and believed that this should be done more frequently as a vesiculitis was not seldom present.

The verumontanum, composed as it was of glandular and cavernous tissue and containing the utricle, ejaculatory ducts, and highly complex nerve supply, was one of the most common focal causes of remote disorders. Not only were there chronic inflammatory conditions accompanied by disproportionately severe sexual and urinary symptoms, but the most remarkable referred symptoms frequently occurred. In a study of 358 cases of chronic prostatitis the writer found that referred pains of varied character were present in a large percentage of the cases. The most common location was the back, 64 cases, then came the perineum 35, suprapubic region 22, hips 10, thighs 12, knee 4, leg 4, simulating sciatica 5, kidney region 8, and simulating renal colic 10. The widespread character was thus evident. In an excellent paper on the remote effects of lesions of the prostate and deep urethra, McCrae cited several cases in which symptoms had been referred to the heart, palpitation, rapidity of rate, attacks in which with precordial distress there was tachycardia, and attacks simulating angina pectoris. The seminal tract was likewise a frequent focus of infection both for tuberculosis and other suppurative processes. The demonstration that the entire seminal tract might be removed without injury of the prostate, urethra, bladder or testicle had brought another region into the radically curative field of surgery.

Dr. YOUNG completed his address by showing lantern slides of anatomical peculiarities that predisposed to focal infection and systemic absorption, and of the pathological changes which led to toxemia or sepsis, and described several surgical measures by which they might be eradicated.

Dr. THOMAS MCCRAE of Philadelphia stated that it might he said that pelvic inflammatory disease in the male was now coming into its own. They had heard a great deal of pelvic inflammatory disease in the female, but pelvic inflammatory disease in the other sex was probably just as important. From the standpoint of internal medicine there were several ways to approach this subject. First he would emphasize the importance of keeping it in mind. If a patient came with symptoms of disturbance of sexual functions or symptoms of genitourinary disease of course attention was directed to the genitourinary tract, but if there was nothing in the symptoms of the patient to suggest disease or disturbance of the genitourinary tract, it was not so easy to discover the etiological factor. It was only by keeping the genitourinary system in mind as a possible source that one would avoid the most serious errors. Disease of the prostate, verumontanum, and seminal vesicles might be responsible for a general nervous disturbance. As an instance of this the case of a young man about whom the speaker had been consulted by the head of large corporation might be cited. This young man did well for a time, and then began to slip back and to become inefficient. The head of the corporation stated that if the man did not do better he would have to discharge him. In consultation the man was very frank and realized that he had lost his grip on things. He said he could not work as formerly, he was beginning to be the victim of fear and anxiety and realized that in transacting his business he did not make a good impression. The man did not drink, and there were no localized hints at all as to his condition. In the examination it was found that he had a general prostatitis and inflammation of the verumontanum, which had given no symptoms of any account. He was treated merely for this local condition, and by the end of three months there was a tremendous change for the better. This man had gained his health and efficiency. According to the statement of the head of the corporation who brought him to me for consultation he was as efficient as ever. Often in cardiac conditions which were called functional one would find the cause in the genitourinary system. These might be designated as anxiety or fear neurosis. Dr. McCrae said he did not want to give the impression that all nervous diseases in the male were due to prostatic disease, but as to the influence of the prostate on the heart too much could not be said. If one believed there was an internal secretion it would be easy to understand and would go far to explain the psychic phenomena associated with disturbances of the prostate. Furthermore, the point should be emphasized that many of these cases gave no local symptoms, and much work had to be done to find the far distant cause. Again, it was easy to recognize a local cause if one took the trouble to make an examination

Dr. EDWARD L. KEYES said that any paper written by Dr. Young was so complete that it rarely admitted of discussion. He wished first to confess that he did not get the results that Dr. Young did by excising the tuberculous seminal vesicles. In some cases he had been fortunate, but as a rule he left the seminal vesicles alone. Dr. Young had stated that rheumatism was unusual in cases of infection of the kidney. One instance had come under his observation, however, in which rheumatism was the only systemic condition due to a renal stone. This patient was cured of his rheumatism by removal of the stone. Dr. Young did not make any reference to the acute pyelitis of infancy in which the symptoms were often so remote from the urinary tract. Two striking points in reference to the pyelitis of infancy were the fact that the symptoms of chronic infections were usually referred to the digestive tract, while acute infections in infancy were often hyperacute. Repeated chills in infancy could only mean malaria or acute inflammation of the kidney. Attention had been called to the great variety of conditions that might be traced to infections of the genitourinary tract. The speaker had seen several cases that were distinctly of the cerebral type, and it was only in the course of a routine examination that the urinary origin of the symptoms was discovered, and relief was procured by drainage.

Dr. WALTER A. BASTEDO said that the important point emphasized by the speaker was that in searching for the cause of obscure internal trouble one should not only look over the teeth, tonsils, and abdominal organs, but should also investigate the genitourinary organs. Dr. Young had referred repeatedly to Dr. Eugene Fuller's work in demonstrating infection of the seminal vesicles. It might be of interest to know that Dr. Larkin, at Dr. Fuller's request, had removed the prostate and seminal vesicles from about 35 consecutive male cases brought to autoposy, and that in a large number of these there was an infection, usually of the streptococcic variety. In regard to the prostatic cases with retention in which there was a low phthalein output, high filtrate nitrogen, and high blood pressure, so that there seemed definite kidney disease, but which, following proper drainage, lost their kidney picture, the speaker asked Dr. Young if he thought the kidney disturbance could be attributed to infection. Would it not rather be due to the damming up of the urine, for though the germs could still be found in the urine, the kidneys were relieved? There was another influence not always thought of, and that was the effect of venous back pressure on the kidney. In the laboratory if one clamped off the renal vein only a little bit the urine flowed slower or even ceased, and this indicated that a comparatively small venous back pressure might cause urinary stagnation in the kidney and ureter, and thus favor urinary infection. This would suggest that urinary infection might be due to disturbances of the circulation. In regard to the psychic state with the anxieties and phobias, a distinction must be made between the genital and the urinary disturbances. In the strictly bladder and ureter and kidney troubles we did not have these phobias, but in the affections of the genital tract they were very common; and as they occurred whether the condition was an infection or not, it would seem that these psychic disturbances were genital or sexual. In these cases whatever would remove the sex tension would tend to relieve the psychic symptoms, whether it was removal of the prostate, or draining the seminal vesicles, or straightening out the uterus, or functional relief. The speaker had had cases of supposed ulcer of the stomach or duodenum, and cases with cardiac irregularities, in whom the psychic sex disturbance was apparently the underlying fault. For example, in the cases supposed to be ulcer one could find no blood in the stools or stomach contents, and no positive string test, though a high hydrochloric acidity; and if one put these patients to bed on an ulcer cure, though they improved for a short period they would soon get very restless, and if they were then kept in bed would have a return of their symptoms. These cases occurred in persons out of wedlock, and after a few days treatment for hyperchlorhydria, one did well to get them into vigorous activity such as horseback riding, or golf, or send them into the woods for a hunt. It did not seem to the speaker that these were cases of genitourinary infection, but simply psychic disturbances related to the sexual organs whether there was an infection or not. In closing Dr. Bastedo said he did not think these

psychic patients should always be sent to the genitourinary specialist, but that often they might with advantage be sent to any physician who was also a philosopher.

Dr. J. BENTLEY SQUIER said that though this work was very interesting, much remained to be learned clinically and Dr. Young had shown that this was also his opinion. The genitourinary tract might be divided into the upper and the lower tract. Most of the infections of the upper tract had been found to be ascending infections. The lymphatics were so arranged that infection from any part of the abdomen might reach the kidney though this route. When medical men took up the study of neurasthenia they got into the habit of thinking that sex neurasthenia was at the bottom of all neurasthenia and as due to some lesion of the prostate, or seminal vesicles, or elsewhere in the genitourinary tract. But one might also include disturbances of the internal secretions, first of the adrenals and then of the hormones, which would result in lowering the threshold of the nervous system. If this source of irritation were relieved the patient would be cured. This was a very fascinating theory and might be taken for what it was worth. It should be remembered that focal infection might occur anywhere from the top of the head to the soles of the feet, or from the mouth to the anus. As a result one might have heart disease, or rheumatism, or many other conditions, and any procedure from the removal of the teeth to a curettage of the uterus might be undertaken for the purpose of curing the condition. So that one might say that where a patient had a condition that might be due to focal infection, the broader the physician was the more likely was he to be correct in discovering the primary source of the trouble and the more successful would he be in dealing with a focus of infection. If a man followed a specialty that might embrace a focus of infection in its field, he was prone to find such a focus there.

Dr. REGINALD H. SAYRE said he agreed with what Dr. Squier had said regarding the importance of finding where the particular focus of infection was that was making the trouble. It might be possible to cure a patient by pulling a tooth or draining a seminal vesicle, but if this result was to be attained it must be done early. A joint was not cured in this way after an arthritis was established. When that stage was reached the joint should be given rest and protection. Dr. Sayre stated that he had seen many cases in which the teeth had been pulled or the tonsils extirpated, or a vesiculectomy performed and the infected joint grew worse, because nothing had been done to protect it; it did not get better until it was treated locally. One should not forget the importance of rest and protection to an inflamed part as well as the removal of the focus of the disease.

Dr. EMANUEL LIBMAN said that while he appreciated that focal infections were of great importance in causing various forms of disease and that their rôle had been for a time underestimated, at the present time there was a tendency to blame conditions upon local foci that were not due to such a cause. This was particularly true with relationship to the question of chronic appendicitis causing various forms of infections. The chronic appendices generally showed more or less complete obliteration. The lesion consisted of a production of fibrous tissue and it did not appear clear how such a focus should be the origin of any infections. It was only rarely nowadays that appendicitis cases in which pus was present, were allowed to become chronic. The only general effect that one could imagine could come from a chronic appendicitis would be by whatever intoxication was caused by stasis in the ileum and by reflex action especially on the pylorus. It was important to be careful in one's use of the term "rheumatism." The term rheumatism should be used in the old clinical sense and in no other way. The disease which we called rheumatic fever was characterized by the tendency to recur, by the lack of suppuration in any joints, by the tendency to the development of pericarditis, chorea, and verrucous endocarditis with Aschoff bodies present in the heart muscle. The only primary focus that was considered as existing in rheumatism was a preliminary tonsillitis. Therefore, if any local focus was present aside from a tonsilitis, the case could not be properly grouped as rheumatic. Cases of joints infected with hemolytic or non-hemolytic streptococci should be called "streptococcus arhtritis" and not rheumatism. Up to the present time it had not been definitely proven that streptococci caused rheumatism. If these cases could all be proven to be due to streptococci, then the term rheumatism could be dropped and the name streptococcus arthritis used to replace it. It was better, however, for the present, to use the term rheumatism for this special group of cases as described above and try to find out what they were due to. The speaker believed that Dr. Rosenow's theory of mutation of the streptococcus and pneumococcus must be accepted. At the Mount Sinai Laboratory they had for many years believed in such mutation, as evidenced by the publication of the work by Drs. Buerger and Ryttenberg in 1907. The speaker took part in those studies at that time, and since then Dr. Aschner and he made studies from time to time, and would in the near future publish some further examples of mutation. It was much more common to see a pneumococcus take on streptococcus features in the body than the other way around. The speaker agreed with Dr. Bastedo in regard to his statements concerning the importance of sexual tension as an etiological factor. To show how far in error one might go in blaming conditions on a focal infection, the speaker was now trying to prevent a woman from having her tonsils and teeth removed for headaches which she herself had confided to him are due to such tension.

Dr. YOUNG, in closing the discussion, said he wanted Dr. Bastedo to realize that he did not want everybody sent to the genitourinary surgeon, but he wanted the general practitioner educated so that he would realize the importance of a rectal examination and that he might know that it was possible to get a portion of the seminal vesicle and make an examination under the microscope which would give him definite information. In regard to the back pressure and infection, there was no question but that back pressure led to a deterioration of the kidney; it lowered the functional capacity and increased the output of urea, etc., and thus made the secondary changes more rapid in the heart and arteries. The neurological and psychical disturbances were not necessarily due to the focal infection but to the results produced by the focal infection or possibly by a cicatrix. In a chronic vesiculitis there might be a cicatricial contracture and from it pressure that caused a neurosis. The neuroses coming from that small area were widely separated and of great importance.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

COLLEGE OF PHYSICIANS AND SURGEONS OF ONTARIO.

Final Examinations, May, 1916.

MEDICINE.

Answer five questions only.

1. Describe the clinical course of an average case of acute lobar pneumonia terminating favorably, giving the usual physical signs noted over affected lung at various stages of progress.

2. Discuss the causation, symptoms, differential diagnosis and treatment of catarrhal jaundice.

3. Describe the causation, symptoms, differential diagnosis and treatment of epidemic cerebro-spinal meningitis.

4. (*a*) Give the causation, diagnosis, course and treatment of tinea tonsurans (ringworm of the scalp). (*b*) Give the diagnostic features and detail treatment of scabies.

5. What are the most common types of growth in brain or brain membranes causing symptoms of cerebral tumor? Discuss the general symptoms of such growths, and give localizing features of a growth in any selected area of cerebrum.

6. A business man, 48 years old, of sedentary habits, with good appetite and using alcohol and tobacco moderately, consults you for frequent headaches and tendency to be forgetful. On examination you find a high tension pulse, systolic blood pressure of 190 mm., while urine shows a trace of albumin and a few hyaline casts. Describe further examinations you would think necessary, and discuss diagnosis, prognosis, and treatment.

SURGERY.

1. (*a*) Describe the symptoms of fracture of the spine at lower dorsal region. (*b*) Give treatment. (*c*) Give indication for operation. (*d*) Describe the operation.

2. (*a*) In what diseases of the kidneys do you consider its removal advisable? (*b*) Give differential diag-

nosis between any two of these diseases. (*c*) Describe the operation for removal.

3. (*a*) Give symptoms of ulcer of the stomach. (*b*) From what other diseases must it be differentiated? (*c*) Under what conditions is operation necessary? (*d*) Describe the operation.

4. (*a*) Describe the symptoms of a strangulated hernia (inguinal). (*b*) Give methods of treatment. (*c*) Describe the operation when the intestine is gangrenous.

5. (*a*) Describe the symptoms of a fracture of the middle of the femur. (*b*) Give treatment in detail in an adult.

OBSTETRICS AND GYNECOLOGY.

1. Cystitis: give causes, course and treatment.

2. Describe the operation for (*a*) a recent laceration of the perineum, (*b*) an old laceration, and (*c*) mention the most important features of each case.

3. What conditions are often mistaken for pregnancy? How would you establish a diagnosis?

4. Define accidental hæmorrhage and give its prognosis and treatment.

5. Give (*a*) the characters and duration of normal lochia, (*b*) causes of suppression, (*c*) causes of prolonged continuance.

ANSWERS.

MEDICINE.

1. *Acute lobar pneumonia* "begins with a severe and usually protracted chill, followed by a rapid rise of temperature, 103° to 104° F., a strong, full, but rapid pulse, soon showing evidence of embarrassed cardiac action. There are also present pain near the nipple, aggravated by pressure, breathing, or coughing; shortness of breath, the number of respirations increasing to 40, 50, or more a minute; disturbance of the ratio between pulse and respiration; and cough, at first short, ringing, and harsh, followed by a scanty, frothy, mucoid expectoration. The sputum soon becomes transparent, viscid, and tenacious, changing about the second day to the familiar rusty sputum. The quantity is increased and a yellow color is assumed as the disease advances. The prostration is pronounced. The face is flushed, especially over the malar bones. The lips are more or less blue and herpes may be observed. Epistaxis, headache, sleeplessness, and gastric disturbances are common. The tongue is coated, the appetite is impaired, and there is constipation. Delirium is sometimes present. The urine is small in amount, highly colored, deficient in chlorides, and often slightly albuminous. The blood shows evidences of leucocytosis. The fever usually reaches its maximum within twenty-four hours and continues high, with diurnal remissions, until the fifth, seventh, ninth, or eleventh day, when a crisis occurs, and within twenty-four hours all the symptoms are lessened, the fever absent, and convalescence is established. Occasionally, the termination is by lysis.

"*Physical signs over the affected lung:* Palpation during the first stage shows the vocal fremitus to be more distinct than normal. In the second stage, the vocal fremitus is markedly exaggerated, except in case of occlusion of the bronchi by secretion. In the first stage, the percussion note is slightly impaired at times, having a hollow or tympanitic quality. In the second stage there is dullness over the affected parts, with an increased sense of resistance. In the first stage there is a feeble vesicular murmur, associated with the true vesicular (crackling) râle, heard at the end of inspiration only. In the second stage there is harsh, high-pitched, bronchial respiration, at times resembling a to-and-fro metallic sound, except when the bronchi are filled with secretion. Bronchophony is present and at times pectoriloquy may be heard. In the third stage, the breathing changes from bronchial to bronchovesicular and the crepitant râle returns. As resolution proceeds, the breath sounds are associated with large and small moist and bubbling râles."—(Hughes' *Practice of Medicine.*)

2. CATARRHAL JAUNDICE. "*Causes.*—Extension of gastrointestinal inflammation is the most common cause. Atmospheric changes, passive congestion of the liver, and the infectious fevers are less frequent factors.

"*Symptoms.*—The affection begins with epigastric distress, coated tongue, impaired appetite, nausea, with perhaps vomiting, looseness of the bowels, and slight feverishness. In from three to five days the eyes become yellow, and jaundice gradually appears over the whole body; the feverishness disappears, the skin becomes harsh, dry, and itchy, the bowels constipated, the stools whitish or clay-colored, accompanied with much flatus and colicky pains; the urine heavy and dark, loaded with urates and containing biliary elements. When the jaundice is complete, the surface is cold, the heart's action slow, the mind torpid and greatly depressed, and there is pain or tenderness on pressure over the hepatic region. The symptoms subside within a few days after the jaundice appears, but the depression, discoloration, and condition of the bowels persist for one or two weeks."

"*Differential Diagnosis.*—When jaundice is induced by obstruction to the outflow of bile other than that produced by inflammation, such as arises from stricture of the common duct, tumors of the abdominal viscera, foreign bodies such as gall-stones and parasites, fecal accumulations, spasms of the bile ducts due to emotion, etc., the symptoms of these different affections will be found associated with the icteroid manifestations. *Non-obstructive or hematogenous jaundice* is unassociated with inflammatory changes in the bile ducts, and arises from disintegration of the blood or hemolysis. It differs from catarrhal jaundice in its history, the absence of clay-colored stools, and less staining of the urine.

"*Treatment.*—The patient should be placed at rest in bed and the diet restricted to milk and lime-water, broths, eggs, lean meats, etc., care being taken to eliminate all starchy, fatty, or saccharine substances. Calomel, gr. ¼, with sodium bicarbonate, gr. ij, should be then given every two hours until twelve doses are taken, followed by Hunyadi water. Sodium phosphate, ʒj, may also be given, well diluted, every four hours. The dry, itching skin may be relieved by diaphoresis, a hot bath containing potassium carbonate night and morning, or a weak carbolic acid solution. If insomnia is present potassium bromide, gr. xxx, may be administered. Diuretics are indicated if the urine continues scanty, preference being given to the alkaline waters, potassium bitartrate lemonade, and spirit of nitrous ether, ♏x to xx. In cases in which the constipation persists, aloes, podophyllum, colocynth, and other cholagogues should be employed. Irrigation of the colon once daily with cold water, gradually increasing the temperature, is often very effective."—(Hughes' *Practice of Medicine.*)

3. CEREBROSPINAL MENINGITIS. *Causation.*—The disease is caused by the *Diplococcus intracellularis meningitidis;* other microorganisms are also supposed to be capable of causing the disease. Predisposing causes are bad hygiene, overcrowding, foul air, poor food. The diplococcus is believed to gain entrance to the body through the nasal mucous membrane, and the infection leaves the body through the same channel. "Carriers" may transmit the disease through their nasal discharge. *Symptoms:* Sudden onset, with headache, vomiting, rigors, stiffness of neck and back producing opisthotonos, pulse full and rapid, temperature about 102° F., photophobia, delirium; Kernig's sign is present, and the diplococci may be found in the cerebrospinal fluid after lumbar puncture; the tâche cérébrale may be observed, and leucocytosis is present. The *diagnosis* is made from the symptoms, chiefly the presence of Kernig's sign and the diplococci in the cerebrospinal fluid. In *typhoid fever* the onset is gradual, the temperature is characteristic, the opisthotonos and Kernig's sign are absent, there are no diplococci in the cerebrospinal fluid, and Widal's reaction may be present. *Tuberculous meningitis* is not epidemic, is not of sudden onset, and a primary focus of tuberculosis may generally be detected elsewhere. *Treatment:* Isolation in an airy room, rest in bed, nourishing diet, ice bags to the nape of the neck, morphine for the pain, bromides for the restlessness, lumbar puncture to relieve the symptoms, and the injection of Flexner's serum. Stimulation may be necessary.

4. *Tinea tonsurans* (ringworm of the scalp) is a contagious affection due to the *trichophyton fungus* which invades the hair and hair follicles. It generally occurs in children, and is characterized by small circumscribed patches of baldness in which the hair is diseased and often broken off close to the scalp. Vesicles, pustules, and scales are observed. The patches spread and may be as large as a silver dollar. Itching is a constant symptom. The diagnosis is made certain by the presence of the fungus; a hair should be extracted, immersed in liquor potassæ, and then examined under the microscope. Vigorous and persistent local treatment is

required. The hair of the affected part should be cut close, and the head washed daily with soap and hot water, or an ointment of oleate of mercury, or of sulphur should be applied twice a day. Treatment must be continued as long as the fungus is present.

Scabies.—The diagnostic features are the presence of the itch mite (acarus scabiei) and its burrows. The eruption is multiform and generally on the flexor surfaces of the body, and the itching is intense and is worse at night. *Treatment* consists of a hot bath, followed by the application of sulphur ointment (one dram to the ounce of petrolatum) every night for a week; the bed linen and underclothes should be sterilized. After the interval of one week treatment must be undertaken again for a week.

5. The common types of cerebral growths are the tubercle, gumma, sarcoma, carcinoma, and cysts. The general symptoms are those of apoplexy: There may be prodromal symptoms such as vertigo, pain in the head, or impairment of memory; but as a rule the attack is sudden with vertigo and unconsciousness; there may be retention or incontinence of urine, the urine has a high specific gravity and may contain albumin; hemiplegia generally ensues; the tongue protrudes toward the affected side; aphasia (either motor or sensory) may be present; the face is flushed, breathing is stertorous; the body temperature is first subnormal and then elevated; the pulse is slow and full; in severe cases the pulse becomes weak, and the respirations become of the Cheyne-Stokes type; the reflexes are abolished.

If the tumor is in the prefrontal region, there may be no symptoms at all, or mental enfeeblement, disturbances of smell and vision, motor agraphia and aphasia.

6. A complete physical examination should be made, noting especially the condition of the heart, arterial walls, and abdominal organs; the diastolic blood pressure should also be obtained; the urine should be examined, noting the specific gravity, 24 hours quantity, presence of sugar and indican, and the amount of urea excreted; the patient should be questioned about the amount of rest, exercise, and recreation (including vacation) which he takes; the eyes should be examined by a competent oculist and any errors of refraction should be corrected; a Wassermann test should be made.

The *diagnosis* lies between nervous fatigue, eyestrain, simple hypertension, gastrointestinal autointoxication, arteriosclerosis, chronic interstitial nephritis, and syphilis. *Prognosis.* If the condition is dependent upon causes which may be removed, the prognosis is fairly good so long as there are not marked changes in the bloodvessels. With organic arterial changes there is danger that these symptoms may be precursors of cerebral hemorrhage or thrombosis, in which case the outlook for future health and usefulness is bad, and for life doubtful. *Treatment.* The *indications* are:—For *gastrointestinal autointoxication*, the diet must be regulated, the total amount limited, and the quantity of proteids restricted; laxatives, especially salines, should be given. For *nervous fatigue*, more sleep, or a vacation may be required. *Syphilis* requires cautious treatment with mercury, arsenic and potassium iodide. *Arteriosclerosis* requires a restricted diet (as just given for autointoxication), also potassium iodide (10 grains, three times a day) for a long period, nitroglycerin (gr. 1/100 to 1/50) may be tried, and if no bad effects are noticeable in heart, circulation or urine, it may be used as required; sodium nitrite may be used instead; the patient should avoid overeating, constipation, and exposure to chills, and he should limit his business activities (at least for a time); alcohol and tobacco should be limited to the smallest amount compatible with physical comfort, and beer and heavy wines should be avoided. Moderate exercise as walking, golf, etc., should prove beneficial. *Chronic interstial nephritis* requires the same treatment as just outlined for arteriosclerosis, but in addition it might be advisable to avoid red meats.

SURGERY.

1. In fracture of the spine in the lower dorsal region, there will be paralysis of the muscles of the lower limbs, with total anesthesia of legs and gluteal and perineal regions; there may be paralysis of the bladder or retention of urine with overflow, according as the vesical center is or is not involved; there will be incontinence of the feces. The extent of the paralysis and anesthesia depend on the lesion to the cord; if only one side of the cord is affected, only one limb will be paralyzed and anesthetic. The parts immediately above the lesion are hypersensitive, and there is a zone of pain around the body ("girdle pain"). Bedsores arise on very slight irritation, cystitis usually comes on from septic infection, the temperature and pulse are variable (according to the amount of toxic absorption). "The *treatment* naturally varies with the character of the case. The patient is carefully placed on a prepared bed, the greatest gentleness being used in handling and lifting him, for fear of increasing the damage to the cord. The bed must be firm though not hard; perhaps the best type to employ is a horsehair mattress placed over fracture boards; nothing more soft or yielding is permissible. Spring beds and wire-wove mattresses are most undesirable. A water-bed is required in the later stages, but should not be used at first, as it is scarcely firm enough. The shock resulting from the accident is treated in the usual way by warmth and, if need be, by stimulants; but it must be remembered that anesthetic regions of the body can be easily blistered or burnt by hot-water bottles, unless carefully guarded by flannels. When reaction has occurred, a more thorough examination of the patient can be made, and the subsequent course of action decided on. In many cases, as soon as the patient is laid flat on a bed, the displacement remedies itself, especially if the spine has been comminuted, and then the treatment must be *symptomatic*, as also after reduction or operation, where the paraplegia persists or is only slowly recovered from. He is kept in bed, absolutely flat, and with the head low; perhaps some form of mechanical support—*e. g.*, a plaster of Paris or leather jacket—may be considered advisable; but its application is always a matter of difficulty, and in the early stages it does but little good. Food is regularly administered, and at first must be light and readily assimilable. The chief care of the attendants must be directed to the skin, bladder, and bowels."—(Rose and Carless' *Manual of Surgery.*)

Indications for operation (laminectomy).—When the cord is not completely severed; in fractures of the arches alone when the cord is pressed upon; when the paraplegia comes on slowly, after an interval. When there is complete local destruction of the cord no operation should be done.

Laminectomy.—"The patient is placed either prone or lying on his left side with a pillow supporting the chest, and the spinous processes of the vertebræ to be dealt with are exposed by raising a rectangular flap of skin and fascia. When there are signs of fracture of the neural arches, the center of the flap should lie over the broken vertebræ. When there are no signs of fracture, the site of the incision is determined by the spinal symptoms. The muscles, along with the periosteum, are separated from the spines and laminæ, and the hemorrhage, which is often very free, is arrested by pressure and forceps. The interspinous ligaments are then divided with scissors, and the spines snipped off at their bases with bone pliers. The ligamenta subflava are next divided close to the bone and the laminæ sawn across and levered out, or cut away with rongeur forceps. The fatty tissue outside the dura is separated, and any veins that are torn are tied. The extra-dural space is now examined by pushing aside the dura with the enclosed cord, and any blood clots or fragments of bone which may be present are removed. If it is necessary to open the dura, it should be securely sutured again to prevent leakage of cerebrospinal fluid. The divided muscles are brought together with catgut sutures, but, as there is usually a good deal of oozing for some hours after the operation, a drainage tube should be inserted down to the gap in the bone, and left in position for forty-eight hours. Special care must be taken to avoid soiling of the dressings by discharges from the paralyzed bowel and bladder."—(Thomson and Miles' *Surgery.*)

2. *Removal of the kidney may be advisable* in extensive tuberculous disease of the kidneys, calculous pyonephrosis, hydronephrosis, malignant disease, and rupture of ureter or kidney if complications are present. In any case, before deciding to remove one kidney it must be positively ascertained that the patient has another kidney capable of performing its functions.

Tuberculosis of the kidney shows polyuria, acid urine which may contain pus or blood, the sediment may contain tubercle bacilli. If no tubercle bacilli are found microscopically, some of the sediment injected into a guinea pig will cause tuberculosis in that animal. Cystoscopic examination with catheterization of ureters will show which kidney is affected, and tuberculous ulcers in the bladder may also be detected close to the ureteral orifice.

Malignant disease of the kidney gives hematuria, pain in loin and thigh, and emaciation. A tumor may be palpable. Cystoscopic examination gives none of the features noted above, and there are no tubercle bacilli in the urine.

Nephrectomy.—"The abdominal operation is chiefly utilized when the organ is much enlarged, on account of the readier access obtained, especially to the pedicle. The peritoneum is likely to be opened, and may be exposed to septic contamination, when the pelvis and the upper part of the ureters are distended with decomposing pus, as is frequently the case; but this is easily prevented. Drainage is obtained for the cavity left after the removal of the organ by a counter opening made through the loin. One great advantage is that the other kidney can be first examined, if required, and its condition ascertained. As to the technique, there is frequently no necessity to open the peritoneal cavity, since the kidney is almost always enlarged, but an opening is often made, intentionally or accidentally. The colon and peritoneum are peeled off the organ and displaced inwards; it is then freed from its adhesion to surrounding tissues, the surgeon endeavoring to keep outside its true capsule, but inside the layer of condensed perinephric tissue. Special precautions must be adopted in dealing with the deep aspect of the tumor, particularly on the right side, where it is occasionally adherent to the inferior vena cava. The mass is now lifted from its bed, and its pedicle, consisting of the ureter and renal vessels, isolated. These latter are secured separately by ligature and divided, a clamp being applied to the distal ends. The ureter is dealt with in the same way, small pieces of gauze being packed around so as to receive any secretion which may escape; the exposed mucous membrane in the portion which is left is carefully touched over with pure carbolic acid. The kidney thus freed is removed, and the wound in the abdominal parietes closed in the usual way, provision for drainage having been previously made either through the loin or from the front. Considerable shock is often experienced from this operation and the death rate is somewhat high. Occasionally the perinephric adhesions are so firm and extensive that the only practicable plan of removing the organ is to enucleate it from within the capsule as far as the hilum; the capsule is then torn or cut through so as to expose the pelvis and renal vessels, which are secured."—(Rose and Carless' *Manual of Surgery.*)

3. Ulcer of the stomach. *Symptoms.*—Pain, which is intermittent in character, localized in the stomach, and coming on soon after a meal; vomiting, which also occurs soon after eating, and often relieves the pain; hematemesis is common; examination of the gastric contents shows an excess of free hydrochloric acid.

It is to be *differentiated from* cancer of the stomach, duodenal ulcer, gastralgia, gastritis, pylorospasm, hypersecretion, cholecystitis, cholelithiasis, and renal calculus.

Operation is indicated when the hemorrhage is copious and recurrent, when medicinal treatment has been given a fair trial and no cure has been made, when after apparent cure a relapse has occurred, when perforation occurs, when adhesions about the stomach interfere with the proper performance of its functions.

Posterior gastroenterostomy.—"The abdomen is opened by a vertical incision to the right of the middle line above the umbilicus. The stomach, transverse colon, and omentum are drawn out of the wound and turned upward, and an opening is made in the mesocolon near its root, so as to expose the posterior surface of the stomach; a portion of stomach at the lowest part of the greater curvature is selected for the anastomosis. The upper part of the jejunum is then found by passing the fingers along the under surface of the mesocolon immediately to the left of the spine, and the highest available portion of it brought into contact with the stomach in such a way that the loop of bowel selected runs from right to left (Mayo). An anastomosis is then made between the stomach and jejunum, an ellipse of mucous membrane being excised from each viscus. The edges of the opening in the mesocolon are then stitched over the line of junction, so as to bury it and prevent any hernial protrusion through the gap. After being cleansed, the viscera are replaced in the abdomen, and the wound in the parietes closed. When the patient has recovered from the anesthetic he is propped up in bed with pillows."—(Thomson and Miles' *Surgery.*)

4. *Symptoms of strangulated hernia: General.*—"Severe pain comes on suddenly after some effort, at first referred to the umbilicus, and subsequently to the site of the hernia. This is accompanied by some shock. The pulse is weak, and, though slow at first, becomes rapid; the skin is cold and clammy; vomiting occurs, and soon becomes frequent and fecal-smelling. Constipation is complete, though both feces and flatus may be passed at first from the lower bowel. The patient generally becomes exhausted from the vomiting and inability to take food. When gangrene occurs the temperature becomes subnormal, the pulse very rapid and weak, and the patient dies of toxemia from the general peritonitis which follows gangrene. *Local.*—A tumor forms at one of the hernial sites; or more often the patient has been the subject of a hernia, which he now finds to be irreducible, tense, tender, and without impulse on coughing. If allowed to persist the sac and coverings become gangrenous."

Treatment is taxis or operation. "Operative treatment should be undertaken at once when gentle taxis has failed. An incision is made over the sac, which is then opened. There is usually fluid in the sac, so there is no danger of wounding the gut. The fluid is washed away, then the cause of strangulation is made out, and a hernia knife guided up to it by a finger or broad hernia director. The constriction is nicked in one or two places and the gut is drawn down so that the site of strangulation may be examined. Omentum is ligatured and removed. If the patient is profoundly collapsed and will not bear a prolonged operation, an artificial anus is established by dividing the constriction outside the sac, so as not to open the peritoneal cavity. The loop of bowel is then opened to give free exit to the feces. Most of the cases which have to be treated in this way are so bad before treatment is commenced that a fatal termination must be expected. If the patient can possibly stand it, immediate resection gives the best chance, and with Murphy's button or a bobbin much time can be saved. A radical cure is advisable after the strangulation has been relieved, unless the patient's condition contraindicates it. Liquid food is given at the end of twenty-four hours, and the bowels need not be disturbed for five or six days, when castor oil may be given."—(*Aids to Surgery.*)

5. *Symptoms of fracture of the middle of the femur.*—History of injury; disability; pain on movement; preternatural mobility; crepitus; shortening of the limb, deformity (simple overriding of fragments, or angular deformity). The lower fragment is drawn upward and inward, and may be either in front of or behind the upper fragment; the ends of the fragments can be felt by the surgeon. The thigh and leg are slightly flexed and, generally, everted.

Treatment: "The limb is carefully washed and, if hairy, shaved. Two long strips of strapping, three inches wide, fixed below to a square piece of board ¼ to ½ inch thick (slightly wider than the ankle opposite the two malleoli), which is known as the stirrup, are heated and pressed against the lower third of the fractured limb. They are here secured by short, thin pieces of strapping 1 to 1½ inches in width, passed in a figure of 8 around the limb above the malleoli and ending just below the fracture; the knee may be left uncovered. It is necessary to see that the pull of the extension is exerted on the femur and not on the knee. Large pads of wool should be introduced between the malleoli and the sides of the strapping, to prevent the skin over these processes becoming chafed. A cord is fixed to the stirrup and passes over a pulley at the end of the bed, and is there secured to a tin can which is filled with shot up to the required weight. If now the foot of the bed is raised on blocks, extension and counterextension are obtained, the patient's body acting as a counter-extending weight. When the fracture has been manipulated into a good position under an anesthetic (it is always necessary to control the fracture with some splints before the anesthetic is given), the extension apparatus is applied, and Liston's splint is bandaged to the limb. A proper splint of this kind should extend from the axilla to below the foot, and it is secured to the patient in three places: (1) round the thorax, (2) round the limb at seat of fracture, and (3) to the leg and ankle. In securing the thorax it is necessary to take the first turn of the bandage round the splint from within outward, and then round the back of the patient's thorax, the direction of the bandage in this way preventing the natural tendency of the splint to rotate forward. Several turns should be taken round the thorax in order to retain it in position. The remaining bandages should be secured from without inward, in order to check the tendency of the foot and

leg to roll outward. In order to prevent the rotation of the limb a method devised by Cheyne and Burghard may be adopted. This consists in securing the limb at the level of the popliteal space to a short splint, 8 by 4 inches, by means of a plaster of Paris bandage. The presence of this splint effectually prevents any rotation, either inward or outward. Special care must be taken to see that the malleoli and the skin over the heel are not subjected to any great pressure. If the fracture is put up in this way it must be kept up for six to eight weeks, and the amount of weight applied to the limb must be varied according to the age of the patient and the tendency to deformity. Roughly half a pound a year will be found to answer most purposes, but if there is much spasm the amount can be increased up to 20 pounds. At the end of six weeks, during which period the limb should have been regularly massaged—this can usually be done without disturbing the extension—the patient should be got up, and some form of retentive apparatus applied. A Thomas's splint is a very valuable form of apparatus, since it enables the patient to get about, and allows of active movements being undertaken, while he himself can hobble about on crutches. If such treatment is not considered advisable, he should be kept in splints for eight weeks, and then allowed to lie in bed without any apparatus on at all, while the limb is regularly massaged, and he should be encouraged to get up for a short time on crutches, gradually exercising the limb, until at the end of about ten weeks he is walking on it as before."—(Pye's *Surgical Handicraft*). Some surgeons advise immediate operation, and cut down on to the fractured bone and, after reduction, fix the fragments by two or three Lane's plates.

OBSTETRICS AND GYNECOLOGY.

1. CYSTITIS.—*Causes:* Retention of urine, tumors, foreign bodies, calculus, ammoniacal urine, various pathogenic bacteria producing (for example) gonorrhea, tuberculosis of genitourinary tract, pus in the urine. *Symptoms:* Frequent urination, with tenesmus and a burning sensation in the urethra; later on pain in the bladder, hematuria, and the urine contains pus and epithelial cells. Chills, fever, rapid pulse, and headache may also be present. A feeling of weight or pain in the pelvis is noticed. *Treatment:* Rest in bed; the imbibition of plenty of milk and water, and the avoidance of all highly seasoned food; laxatives; diuretics; sitz-bath; irrigation of the bladder with an antiseptic solution; hot fomentation and vaginal douches are often helpful; sometimes intravesical medication is necessary.

2. (*a*) *Operation for recent laceration of the perineum.*—"The parts are cleansed and a pledget of sterile cotton or gauze pushed up the vagina to stop any flow from the uterus obscuring the wound. The sutures (preferably of aseptic silk) are passed with a moderately curved needle about 2 inches long as follows: Beginning at the posterior end of the laceration (that nearer the anus), the needle enters the skin near the edge of the wound and follows a circular course until its point appears at the very bottom of the laceration (a finger of the other hand in the rectum guarding against its penetrating that canal); it then enters the opposite side of the laceration at the bottom of the wound and comes out of the skin opposite its point of entrance, having followed a similar circular course to that pursued on the other side where it first went in. The ends are *loosely* tied or secured by catch-forceps, until the requisite number of sutures are passed in a similar manner (half an inch apart), when the wound is again cleansed, the vaginal plug removed, and the sutures tied tightly enough to coapt the parts without injurious constriction, the order of succession in tying being that in which the sutures were passed.

In "complete" lacerations—those of the third degree—through the sphincter ani to the rectum, the operation is more difficult. The rectal tear is first stitched with *catgut* sutures (a short, curved needle being used) and going through the rectal wall only. The sutures are tied on the inside, so that the knots are on the mucus membrane of the bowel. They begin from above and come down to the sphincter ani, the cut ends of which are drawn out with a tenaculum while the sutures penetrate them. These *catgut* sutures need not be removed; they will digest in the tissues and disappear of themselves. The posterior wall of the vagina is next sutured with fine silk, from above downward toward the hymen. Finally, skin sutures through the perineum itself, including muscles of the pelvic floor (as just described for lacerations of the first and second degrees) complete the operation. The silk sutures may be removed in about a week. Antiseptic dressings are applied as after an ordinary labor, extra care being taken to keep the wound aseptically clean by daily irrigation with the creolin solution."—(King's *Obstetrics.*)

(*b*) *Operation for old laceration of the perineum.*—"Lateral tears are best repaired by the Emmett operation. With the patient in the lithotomy position, guide sutures or tenacula are passed through the apex of the rectocele and through each labium majus at the lowest carnunculæ myrtiformes. By drawing on the lateral suture and pulling the central suture downward and to the opposite side, the lateral sulcus appears as a triangle with the apex up in the vagina. This triangle is denuded of mucous membrane by cutting off long strips by means of forceps and scissors, or by dissecting the mucous membrane off in one piece. The triangle on the opposite side is treated in the same manner, and the denudation completed by removing the mucous membrane between the bases of the triangles and below the central suture. Each lateral triangle is closed by interrupted sutures of chromicized catgut or silkworm gut, the latter being shotted. The needle, which should be curved, is entered near the margin of the wound on the outer side, passed deeply to catch the fibers of the levator ani, and brought out at the bottom of the sulcus, at a point nearer the operator; it is then reinserted at the bottom of the sulcus, and passed upward and backward in the rectocele, to emerge opposite the point of the original insertion. The opposite triangle is treated in the same manner, which leaves a small raw area externally to be closed. The upper or "crown stitch" passes through the skin of the perineum below the lateral guide suture, then through the rectocele below the central guide suture, and finally through the tissues below the opposite guide stitch. As many sutures as may be necessary are inserted below this. If silkworm gut is used, the stitches should be removed on the tenth day. The external genitals are irrigated with weak bichloride of mercury solution after each urination; catheterization should, if possible, be avoided. The bowels are moved on the second day. Internal douches are not needed unless there be infaction. The patient should be kept in bed two weeks, and heavy work and sexual intercourse forbidden for three months."—(Stewart's *Surgery.*)

(*c*) The chief difference between the two operations, is that in the *recent* condition denudation is unnecessary (except for the possible trimming off of any ragged edges of the wound).

3. The conditions which may be mistaken for pregnancy are, uterine fibroid, ascites, ovarian cyst (or other tumor), fat, pseudocyesis, and subinvolution of the uterus.

Pregnancy.—Positive signs of pregnancy: Hearing the fetal heart sound; (2) active movement of the fetus; (3) ballottement; (4) outlining the fetus in whole or part by palpation; and (5) the umbilical or funic souffle. *Doubtful signs of pregnancy:* (1) Progressive enlargement of the uterus; (2) Hegar's sign; (3) Braxton Hick's sign; (4) uterine murmur; (5) cessation of menstruation; (6) changes in the breasts; (7) discoloration of the vagina and cervix; (8) pigmentation and striæ; (9) morning sickness.

Further, in pregnancy the tumor is hard and does not fluctuate, it is situated in the median line, the cervix is soft, the rate of growth of the tumor and the general condition of the patient's health may help in arriving at a diagnosis.

Uterine fibroid.—Menstruation is irregular and sometimes very profuse; absence of the signs of pregnancy; the tumor is nodular, firm, irregular in outline, and while generally placed somewhat centrally is not in the median line, and is not symmetrical; the rate of growth is irregular, being, as a rule, slow, but sometimes extending over years.

Ascites.—Absence of the signs of pregnancy; the abdomen is distended, but the shape varies with the position of the patient; on lying down there is bulging at the sides, the tumor fluctuates, and percussion shows dullness in the flanks, with resonance in the median line, but the dullness varies with the position of the patient.

Ovarian cyst.—Absence of the chief signs of pregnancy; there may be the characteristic facies, the tumor is soft, fluctuating, is more to one side, and does not show fetal signs.

Fat.—Absence of signs of pregnancy, also of fibroid, or ascites.

Pseudocyesis.—The uterus is not enlarged, and the administration of a general anesthetic causes the collapse of the "tumor."

Subinvolution of uterus.—The uterus does not increase in size, there is a leucorrhea, there is generally pain in the back or ovarian region, there is a history of irregular (and profuse) menstruation, and the signs of pregnancy are absent.

4. *Accidental hemorrhage* is the hemorrhage which occurs when a normally situated placenta separates (partially or completely) from its uterine attachment. The prognosis depends upon the recognition of the condition. If there is an external flow of blood, and the condition is recognized and treated promptly, the prognosis is guardedly favorable; if there is no external flow of blood, but the hemorrhage is concealed, the prognosis is very grave, for the diagnosis may not be made sufficiently early to allow of adequate treatment. In this form, the maternal mortality is at least 50 per cent., and the fetal death rate is 90 per cent. *Treatment:* "The chief indication is to evacuate the uterus as speedily as possible, so that the uterine muscle will contract and close the bleeding sinuses. If the bleeding is slight no immediate intervention may be required except to rupture the membranes. The patient should be kept under close observation, and in bed. Chloride of calcium, gr. xx every three hours, is useful by promoting coagulability of the blood. A very tight abdominal binder and an icebag upon the lower abdomen may help. Generally in either variety of hemorrhage the cervix should be dilated manually. After full dilatation the delivery is rapidly completed by forceps or version, or in dead or nonviable fetus by embryotomy. Firm compression of the uterus is maintained manually by a skilled assistant during delivery. Precautions should be taken against postpartum hemorrhage. When the cervix resists manual dilatation and immediate delivery is urgently demanded, vaginal cesarean section may be performed. The effects of blood loss are combated as in other hemorrhages."—(Polak's *Manual of Obstetrics.*)

5. In the first four or five days the discharge is bloody in character, and is called the *lochia rubra*; it consists of placental tissue, decidua, blood, epithelial cells, mucus, and microorganisms. For the next two or three days the discharge is serosanguinolent, and is called the *lochia serosa*; then for two or three weeks or until the endometrium is regenerated, the discharge becomes creamy, and contains fat, cholesterin, epithelial cells and leucocytes; during this period it is called *lochia alba.* The discharge has a peculiar fleshy smell, something like fresh blood. Ordinarily the lochia continues for from two and a half to five weeks. *Suppression of lochia* may be due to infection or to obstruction of the outflow. *Prolonged continuance of the lochia* may be due to subinvolution of the uterus, posterior displacements of the uterus, and retained secundines; the condition is more common in multiparæ than in primiparæ.

Diazo and Urochromogen Reaction.—Zucker and Ruge regard the urochromogen reaction as more simple in typhoid than the diazo reaction. Dilute 10 c.c. filtered urine with water until it is colorless. Divide in two test glasses and add to one 5 drops of potassium permanganate solution 1 to 1,000, shake well and allow it to stand for a minute. Then compare with the other glass by daylight. The original glass should then give a canary yellow color.—*Münchener medizinische Wochenschrift.*

Simulation of Albuminuria by the Injection of White of Egg into the Bladder.—Hollande, Lepeytre and Gaté state that simulators have mixed white of egg with their urine and have even injected it into the bladder in order to obtain exemption from military service. It is no simple matter to detect this fraud if the albumin is added in small quantities. A solution of equal parts of formol and crystallizable acetic acid should throw down egg albumin in the presence of pathological albumin; and 24 hours after the injection egg albumin will have disappeared from the urine, while in the meantime it steadily diminishes. The microscopic examination should be negative. But tests that are trustworthy *in vitro* may fail in the urine. Maurel's reagent, like that above mentioned, precipitates egg albumin, but also aceto-soluble albumin and albumose, these redissolving when the tube is shaken. The fact that the authors have attempted to obtain specific precipitine reactions and anaphylactic reactions suggests that they are not entirely satisfied with inorganic tests.—*Lyon Médical.*

Therapeutic Hints.

Solvent for the Preservation of Eye Drops.—Harman recommends solvent in which to preserve eye drops:

Distilled water	1 pint
Methyl salicylate	2 grains
Oil of gaultheria	2 minims
Tincture of iodine	2 minims

The mixture is thoroughly shaken, poured into a bottle, and allowed to stand for twenty-four hours, when it may be used. Since aqueous solutions are somewhat wasteful, this may be thickened with gum arabic until it is so sticky that it will hang as a round drop from a lachrymal probe. Atropine, homatropine, and cocaine have the same therapeutic action in this gummy as in aqueous solution, and its use will effect a considerable reduction in cost when expensive eye medicines have to be employed.—*Birmingham Medical Review.*

Kerosene Treatment in Laryngeal Conditions.—T. M. Clayton advises the employment of kerosene in cases of laryngeal diphtheria—together with antitoxin—spasmodic croup, and so-called membranous croup in young children. The dosage is thirty minims every four hours for three doses, then ten-mimim doses three or four hours daily until normal breathing has been established. The unpleasant taste of the kerosene may be disguised by sarsaparilla.—*British Medical Journal.*

Relief for Itching.—The following prescription, while an old one, can be relied upon to give decided relief in cases of itching from various causes:

℞ Menthol	gr. vi
Methyl salicylate	gr. xxx
Oxide of zinc	ʒiij
Lanoline	ʒij
Vaseline	ʒiij

This ointment may be applied over the affected area. —*Bulletin général de thérapeutique.*

A Bladder Sedative.—This prescription is offered as a remedy in the majority of forms of bladder irritability, except where there is strong alkaline decomposition:

℞ Potass. citrat.	grs. x-xx
Sodii bromidi	grs. x-xx
Tr. belladonnæ	♏ v-xv
Tr. hyoscyami	♏ xx-xl
Infus. buchu (recentis)	ad ʒi

Misce. Ft. mist.

Sig.: Two tablespoonfuls in water every four or six hours.

For Cleanliness and Curative Properties in Otitis Media.—Coble, as well as others, uses carbolic acid, 40 to 60 minims, to one quart of water, with which he irrigates the affected ear. When the perforation is very large or the discharge has a foul odor, the accompanying prescription gives good results:

℞ Boracic acid	grs. xx
Ethyl alcohol	ʒj

The canal must be thoroughly cleansed with boric acid solution, dried, then a diluted solution of the above medicine dropped into the canal and allowed to remain until all smarting disappears. To accomplish this the patient should be made to lie down on the well ear, or if both ears are affected flat on the back. A solution of one to three is of sufficient strength with which to begin the treatment, and the strength can be gradually increased until the original prescription can be employed.—*Indianapolis Medical Journal.*

INOPERABLE PERIPHERAL GANGRENE.*

BY W. GILMAN THOMPSON, M.D.,

NEW YORK.

FROM time to time one meets with cases of peripheral gangrene, resulting from various diseases, which, for certain reasons, do not admit of operative treatment, nor, in fact, do they invariably demand it. These reasons may be the advanced age of the patient, a state of extreme debility, a precarious cardio-vascular condition, the hopelessness of the causative disease, or perhaps the refusal of the patient to undergo operation. In such instances the physician must do the best he can to mitigate the evil, and one meets sometimes with surprising results through natural healing or spontaneous amputation.

The writers of a generation past paid much more attention to peripheral or symptomatic gangrene than do more recent authors, from which it may fairly be concluded that its ocurrence was, on the whole, more common in that period.

Present-day writers of medical text books usually omit the topic entirely, or, in enumerating the complications of some important disease, state merely that "gangrene may occur," leaving its site, extent, and gravity wholly to the imagination. One of the most widely read of modern text books refers only casually to gangrene in diabetes as sometimes involving the lung, without mention of its not infrequent peripheral occurrence. Gangrene of the lung, it should be recalled, is less often due to obstructive processes than the consequence of bacterial infection, and hence differs radically from the type of peripheral gangrene which is the subject of the present discussion. The peripheral gangrene of diabetes is usually due to an arteriosclerosis, and is, therefore, most often met with in cases of long duration in patients in middle or advanced life, in whom the symptoms of diabetes have previously been comparatively mild.

Gangrene of the superficial regions of the body appears frequently to have been observed in the severe, acute contagions, and infections, many of which to-day are well known to run a much milder course, as a rule. In such instances it more often involved large areas of the skin, and sometimes the vulva or scrotum, rather than an entire foot or leg, as may be the case with senile or diabetic gangrene. In those cases, doubtless, the condition of the blood and enfeebled heart action were as important factors in its production as embolic processes, endarteritis, or thrombosis. Numerous examples of gangrene of this type have been recorded as accompanying malignant scarlatina and variola, mumps, typhus, diphtheria, and even varicella (varicella escharotica). A number of cases of gangrene of the vulva in measles, and of the penis and scrotum in cholera, have been recorded, and Reynolds early attributed the gangrene sometimes observed in erysipelas, in part at least, to pressure from the effused serum upon the local vessels and tissues. Among the more unusual causes of gangrene, Osler has described a case of multiple gangrenous areas of the skin of the hands and feet in aestivo-autumnal fever. He also cites a similar condition of superficial gangrene observed in typhoid fever after the use of ice bags, and I have met with another case in which quite extensive gangrene of the skin resulted from a too long continued use of the abdominal ice-water coil. Gangrene of the leg has been known to follow typhoid fever, and in one case, that of a boy, the lesion necessitated amputation of the foot. Gangrene is also recorded in leucemia.

Exceptionally, gangrene may result from the constriction produced by scar tissue. MacCallum has reported an interesting case of this sort. The patient was an old man who acquired infected axillary glands. The scar tissue which resulted so constricted the axillary artery as to give rise to a dry gangrene of the hand.

In another group of cases the origin of the gangrene is to be looked for in trophic nerve lesions, as in those sometimes accompanying cerebrospinal meningitis, transverse myelitis, Raynaud's disease, and severe herpes zoster. Cases of distinctly embolic origin are met with chiefly in the lower limbs. I have lately observed a fatal case of gangrene of the leg, which extended up the thigh, in a young man having ulcerative endocarditis; and a number of similar cases have been reported. They would doubtless be more common were it not that the emboli usually reach the brain or some important abdominal viscus before the popliteal vessels.

Quite different are the diabetic cases, in which the development of the gangrene is liable to be quite slow, and often preceded by several days of pain. Most of these cases occur in patients over 50 years of age, but exceptionally the patient may be under twenty. Although the toes, feet, and legs afford the commonest site of the destructive process, it may appear in the buttocks, back, external genitalia, or fingers, where it sometimes follows trauma.

During the past five years, in the Cornell Division of Bellevue Hospital, there have been observed 38 cases of peripheral gangrene due to medical, in distinction from traumatic or visceral, causes. Of these, 19, or one-half, were ascribed to arteriosclerosis, many of which were definitely of syphilitic origin. Eleven more cases complicated diabetes, four accompanied chronic valvular disease of the heart, but only one was assigned to myocarditis. There were two cases with chronic nephritis, and one each with erysipelas, tuberculosis, and hemi-

*A paper read before the Practitioners' Society, Nov. 3, 1916.

plegia. Several of these cases presented features of individual interest. One of those due to chronic endocarditis was probably of embolic origin, for the usual sequence of the gangrenous areas was reversed. Gangrenous areas appeared first in the calves, then over the dorsal surface of both feet, and finally the plantar surfaces and toes became involved. Another case of this type exhibited an aortic stenosis, with a seven months' history of gangrene of the great toe, resulting in spontaneous amputation. A third case was possibly embolic, owing to its very sudden onset and rapid course, although the patient gave no evidence of valvular heart disease, but only of myocarditis. He was in fair health at the age of 74, when, while sitting smoking by his fireside, he suddenly lost all power of motion in both legs. Dry gangrene of both feet rapidly supervened, and spread up the legs to the knees, and the man died one month after the onset of symptoms.

The symptom of intermittent claudication sometimes precedes for several days, or even weeks, the advent of gangrene. It was observed in several cases of the Bellevue series.

One of the diabetic patients was a woman 75 years of age. She had attacks of intermittent claudication in both legs, which finally were followed by complete loss of power. Becoming bedridden, deep gangrene appeared in the buttocks and on other parts of the body not subject to pressure.

With two exceptions, all of the diabetic cases occurred in patients above 48 years of age, two being 75 years old. In one case only was the onset attributable to local injury. Several of the patients on entering the hospital gave a history of previous amputation for gangrene of a toe or foot, but the operation had exerted no control over the spread of the lesion, and was, in this type of case, of doubtful utility. In one case the lesion extended rapidly to the thigh, and in six cases to the leg. In two diabetic cases only was the gangrene "dry." One of these patients was a man 75 years of age, the other was 48, and the latter case was exceptional, for, in addition to a progressive gangrene which finaly required amputation at the upper third of the tibia, following serial amputations of the toes of both feet, the process involved several fingers on each hand. The man had an obliterating endarteritis in addition to diabetes.

Another case of gangrene from endarteritis obliterans was that of a painter only 35 years of age. He did not have diabetes, but a syphilitic osteomyelitis, which resulted in gangrene of the entire right foot. In these cases of obliterating endarteritis (or the thromboangeitis of Bürger) the lumen of the artery is choked by vascular granular tissue, the intima is plicated, but not so thickened as in senile arteriosclerosis, and the condition is of toxic or infectious origin.

My attention was first drawn to the medical treatment of peripheral gangrene early in my medical experience by the case of a man 35 years of age who entered the New York Hospital with an obliterating endarteritis of syphilitic origin. He presented on admission a commencing gangrene of the toes of the right foot which soon extended throughout the entire foot. The visiting surgeons declined to amputate, and the foot was treated by the old fashioned method of applying opium poultices and various soothing lotions to relieve pain, with the effect that the process rapidly extended until at the end of a fortnight it reached the knee, where a well marked line of demarkation appeared. Meanwhile the sloughing of all the soft parts produced so unbearable a stench that the process of dressing the leg made the patient's retention in the ward a serious problem, at least for the other patients. I then applied the method of constant dry heat which I have used ever since in like emergencies. A Bunsen burner was placed on the floor and a stream of air heated to about 150° F. was directed upon the leg through a small caliber stove pipe. Under this constant dry heat the limb was soon mummified, practically all odor disappeared, pain was greatly lessened, and spontaneous amputation took place at the knee joint, the leg being finally suspended by a couple of lateral ligaments which were snipped off with a pair of scissors. The skin healed over the stump and the patient was enabled to leave the hospital, hopping about with a crutch.

A more recent case was that of a colored woman who entered Bellevue Hospital with sloughing gangrene of both feet, which on one side reached half way up the leg, the condition being a complication of advanced diabetes. The case was a hopeless one and the odor was so unbearable that the woman had to be placed in isolation. Dry heat, similarly applied, soon controlled the odor and greatly relieved the patient's pain.

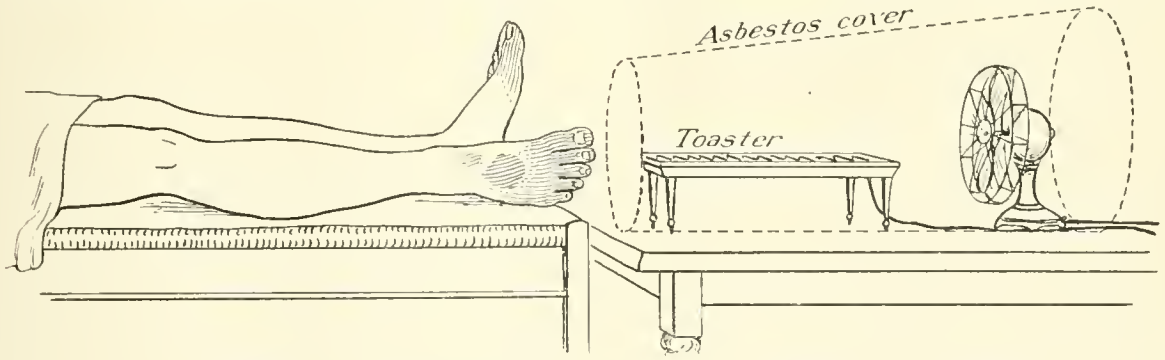
A third case was so unusual in several aspects that a more detailed reference to it is given. The patient was a woman, who previous to her death in her 88th year had an interesting cardiovascular history. With a small frame, poor thoracic expansion, and a uniformly rapid and small volume pulse, her physique suggested a condition of aortic atresia. Late in life, with a senile arteriosclerosis, a definite murmur of aortic stenosis appeared. She remained fairly active, however, until four years prior to her death, when she developed a very rapid and intermittent pulse, a low grade of fever of irregular type, extreme prostration and emaciation. Like many aged persons, she had completely neglected the care of the teeth and the mouth was in such a foul state that it seemed probable that her condition was due to septic infection from this source. A dentist was put in charge, and by almost daily treatments, combined with constant antiseptic care of the mouth on the part of her nurses, after more than two months of fever, the symptoms subsided, the pulse became regular under the use of stimulants and a fair measure of strength returned. Eighteen months later the patient had an attack of bronchopneumonia and for several days death seemed imminent. She, however, again recovered, when she was seized with intense pain in the right foot and leg. Fearing the development of gangrene, the nurses were cautioned to keep the limb warm and watch carefully for local cyanosis. Five days later purplish spots appeared over the ankle and dorsum of the foot, followed by blebs and excoriations, and by the end of the second month it was evident that the entire foot was doomed. The sloughs were treated with aristol, potassium permanganate, aluminum acetate, and a variety of other applications, but the odor became unbearable —so much so, in fact, that it permeated the entire house, and more than once caused the nurses to vomit after attempting to dress the foot. The patient's house being in the country, there was no gas with which to supply a draft of heated air, but there was abundant electric current. I obtained an electric toaster and an electric fan and enclosed them in an asbestos tube which led from the toaster to the foot. The fan furnished a constant current of air, which was superheated in passing over the toaster, and directed across the foot day and night. (See the illustration.) The relief of pain which ensued was remarkable and the patient's incessant moaning and restlessness ceased. By this means the superficial tissues were soon mummified, but every few days a deep slough would open up and the nauseous stench returned. I then resorted to 95 per cent. alcohol, and keeping the entire foot saturated with it, the odor was again controlled, as well as extension of the gangrene, for previous to these two methods of treatment edema, with purplish mottling of the skin, spread half way up the leg, so that it was feared at one time that the process would extend to the knee. Then followed a series of "amputations," first of the toes, then of the metatarsal bones and finally of the astragalus (which proved very refractory), all bones being removed with a pair of dressing scissors. The entire time from the onset of the gangrene until the complete removal of the foot was 14 months. Immediately thereafter a healing process began and, aided by liberal application of balsam of Peru, at the end of four months more the stump was as completely covered with normal skin

as if a primary operation had been performed, which the family had refused, and which the patient's cardiac condition and advanced age might otherwise have precluded. An interesting feature of the case was that owing to the patient's senile childishness and extraordinary care on the part of the nurses never to allow her to see her foot, she never discovered that she had lost it and could not understand why she was not permitted to get out of bed! After the stump was healed the patient gained considerably in strength, digestion improved, and her mental state was that of a happy, good natured child. In this condition she lived for seven months, and finally succumbed to a second attack of bronchopneumonia.

The case is of interest from the point of view of the slow development of the gangrene (through fourteen months), the complete recovery in a patient eighty-eight years of age, and the apparent control of the process by the methods employed.

When the gangrene threatens to involve an opposite limb, as it did in many of the cases above cited, every effort should be made to avert it. The heart force should be strengthened by digitalis, and if blood pressure be high, such as to cause the heart undue exertion, vaso dilators should be given. Massage should carefully and systematically be practiced, and the limb should be kept warm, and relieved as much as possible from the effect of gravitation, and particularly from pressure or trauma.

In cases of parietal thrombosis with only partial occlusion of the vessels, much may be accomplished apparently by these measures.



Home-made apparatus for treatment of gangrene by hot air. The air current, directed by the electric fan, is heated in passing over the electric toaster. A sheet of asbestos covers the apparatus.

Pain in gangrene involving only portions of the general surface of the body is usually absent or inconsiderable, amounting to nothing more than the inconvenience of a superficial ulcer. Quite otherwise is it with gangrene of the extremities, particularly of the feet. In such cases it may antedate any other evidence of the lesion by a week or ten days, and may be regarded as due to a neuritis until the changes in temperature and color of the surface or sensory disturbances appear. It may to some extent be relieved by applications of a hot lead-and-opium wash, a menthol-and-camphor liniment, or similar topical remedy. As the lesion progresses, however, the pain, in many cases, especially in senile gangrene, often becomes unbearable. It is constant and wearing, prevents sleep, and causes great restlessness, so that it must be relieved by morphine. After sloughing appears, however, the hot air treatment often gives remarkable relief. Following spontaneous amputation, and while healing of the stump is in progress, the symptom usually disappears.

I have learned to be chary of a too positive prognosis in certain cases of peripheral gangrene, particularly those occurring in connection with myocardial disease, and, in the aged, with arteriosclerosis. The difficulty is to determine how far back in the circulation the obstruction may exist. With partial popliteal obstruction, for example, the gangrene, beginning in the toes or dorsum of the foot, may extend very rapidly, or, if the obstruction be not too great, the gangrene may remain limited, and be impossible of differentiation from an obstruction localized much nearer the gangrene, with little tendency to cause extension of the process. Some years ago I saw a man of 70 years, in average general health, who presented a gangrene of the entire fifth toe and the contiguous surface of the fourth toe. The fifth toe became so superficially black and shriveled that I urged amputation. This he refused, and I was surprised to find at the end of a couple of months that the toes became entirely normal, and they so remained until the patient's death from pneumonia several years later. A middle-aged woman with myocarditis and attacks of fibrillation developed several large areas of superficial gangrene over the heel and dorsum of the foot. Sloughing ensued, and there was every reason to fear very extensive destruction of the foot, if not of the entire leg; but with local warmth and the energetic use of cardiac stimulants complete recovery from the lesion resulted, and there has been no return during more than two years past. Cases of peripheral gangrene from embolism derived from septic endocarditis are often extensive, and have a uniformly bad prognosis.

In several of the Bellevue diabetic series the development of gangrene preceded death from coma by only two or three weeks, but in one case, which involved the great toes and part of one foot, there was a history of 18 months' duration. Another patient, a man 57 years of age, gave a history of onset of gangrene of the foot, with temporary betterment which preceded by four years his death from coma.

Another exceptional case was that of a tailor 43 years of age who, ten years previously, had suffered amputation of the metatarsi of one foot for diabetic gangrene, after which he remained well and able to work for three years, when the opposite toes became involved, and he had several other minor amputations previous to admission to the hospital. Hence, in the diabetic, gangrene is not necessarily an immediate precursor of death.

In senile peripheral gangrene there is always danger of a pneumonia supervening, or possibly of a gangrenous focus developing in the lung, as in the case of a man 97 years of age who entered the hospital with a superficial gangrene extending over the anterior surface of the left leg and from the middle

of the foot to the knee. The toes were not involved, and the process did not have time to extend beyond the subcutaneous tissues before the patient died of pneumonia.

Much interest and importance attaches to the question whether to advise operation or not in the types of peripheral gangrene above described, and it is impossible to formulate definite rules. The matter, however, is often decided by the patient, who refuses amputation and prefers to take his chance with the spontaneous outcome of the lesion. It is customary, in this event, to resort to wet dressings with such solutions as those of aluminum acetate, weak alcohol (10 per cent.), potassium permanganate, iodoform, iodine, "red wash," etc., but in my experience much more satisfactory results are obtained by the dry treatment with superheated air, reinforced, when the odor becomes unbearable, by absolute alcohol rather than by the weaker solutions.

61 West Forty-ninth Street.

THE MEDICAL CORPS OF THE ARMY AS A CAREER.

By LLEWELLYN P. WILLIAMSON, M.D.,

Major Medical Corps, U. S. Army.

Every medical student during his college years gives serious thought to his career after graduation. Most men hope to put in one or two years immediately following graduation as internes in a large hospital, for, in the present status of medicine, the practical training thus obtained is invaluable in the first few years of practice. To the average student, therefore, the college work and hospital training are taken as a matter of course and are simply preparation for what he is to do in the after years.

And what is he to do? Will he enter practice independently or will he associate himself with some established practitioner? Will he make his start in a large city or in a country town? Will he attempt to take up a specialty at once or will he start in general practice? Or, finally, will he go into one of the Government services?

Many circumstances will necessarily have an influence on the final answer to this question. Personal inclination, personal obligations, finances, available openings, or opportunities must be taken into account; and the advantages and disadvantages of the various careers open to a medical man must be weighed carefully and fitted to the conditions affecting the individual.

In all the affairs of life the question of finances must enter largely and the medical profession is no exception. To the graduate with ample means the matter of finance is not a vital question. After completing his hospital course he could, in normal times, pursue a course of postgraduate study in Europe and can do so very advantageously now in our own country. Later he can select a location best suited to his inclinations and await his time for practice to come to him.

The average graduate, however, must consider the financial side of the question. The cost of obtaining a medical education, and of establishing oneself in practice is great and while in many instances the eventual return on the original investment is large, in the majority of cases it is extremely moderate. The practice of medicine is an honorable profession and for the man who loves it an intensely interesting profession, but for the average man who makes it his life work it has never proved a very profitable profession.

In making plans for a start in practice the location naturally will receive much thought. The large city is, of course, first considered for it is there that the greatest prominence in the profession and the greatest monetary rewards are usually attained. These are, however, slow in coming and a period of from five to ten years of generous outlay and niggardly income is the usual experience of the young doctor locating in a large city.

For the man whose financial resources are small or who has expended a large part of them in getting his medical education, a large city is therefore practically prohibited unless he can form an alliance with an older practitioner who is in a position to start him in practice. Even such a position requires many years of hard work both in private practice and hospital work for which there is little remuneration except the valuable experience gained.

Usually the man of limited means is compelled to start his practice in the smaller cities or country towns. Here he begins to make a "living wage" more quickly, but the chance for anything more than a comfortable living is small. Professionally, too, the advantages occurring to him are never so great as in the large cities.

No matter in what locality the graduate starts he will be subject to keen competition both fair and unfair. In the year 1906 there were in the United States 122,167 registered physicians, a proportion of 1 to every 695 of the then population. In 1916 there are 146,613 physicians, a proportion to the present population of 1 to 691. Thus it can be seen that, while the time required and the cost to obtain a medical education has markedly increased, the proportion of doctors to the population has not diminished, and the average estimated income for all physicians in the United States is to-day $1,200 each per annum. In addition to the fair competition to be expected from this surplus of doctors, the fee splitter, the osteopath, the chiropractic, the optometrist, and the Christian Scienist are all developments of recent years and make marked inroads on the practice of the conscientious physician.

In addition to the worries of competition there are many demands on the physician's time and energies for charitable work, which frequently it is to his ultimate advantage not to refuse. And much time must also be devoted to making friendships both professional and otherwise from which, eventually, practice may be gained. Not until after the average physician has practised many years is he able to avail himself of vacations and the periods of study at medical centers which are so necessary now in the rapid growth of medical science.

Having considered the prospects for practice in civil life, what may the medical man expect if he decides on the army as a career? What are his prospects financially and professionally? And what will the army give him in the general scheme of life?

Financially, he can never get the great rewards which come to some successful physicians in civil life. On the contrary, however, from the time he is commissioned he is assured a comfortable living, his pay, and emoluments gradually increasing as the years go by. An attractive feature to the army service is that the pay of a medical officer and the allowances by which his pay is supplemented go on as long as he conscientiously performs his duties.

and there is no loss of income because of illness or an occasional vacation.

If, through illness, an officer is compelled to relinquish his work, he is put on the retired list and, while his income is decreased somewhat, it will still be sufficient to afford him a living. At the age of 64 all officers are placed on the retired list with three-fourths of the pay they were receiving at the time they reached retiring age. This pay will provide an ample competence as long as the officer lives. The question of "putting aside something for a rainy day" does not enter so intimately into the medical officer's calculations therefore as it does in the life of the civil practitioner.

What are his prospects professionally? In the old days the position of the army doctor was similar to that of the village physician. He was, in effect, a family doctor. In those days the army was stationed in frontier posts and each post was a village in itself with the ranch people and farmers outside forming an available clientele for additional income for the army doctor. He had to care for all the various illnesses occurring among the male and female inhabitants of the post and also was usually called to attend to similar ailments among the population of the surrounding country.

At the present time conditions in the army and consequently conditions in the army medical service are very different. The old frontier post is gone and now the army is beginning to be organized in divisions and brigades and stationed in large posts. The result is that the practice of medicine in the army has taken on the aspects of the practice of medicine in cities. At every post there is a large hospital perfectly equipped with all the medical, surgical, and laboratory appliances now necessary for the modern practice of medicine. Because of the number of troops stationed at each post and the families of the officers and men also living there, the source from which medical material comes is large and varied. At every post hospital cases of all kinds may be constantly found and medicine and surgery in all its branches finds ample scope in which to employ its talents. In addition to the post hospitals there are large general hospitals at Washington, San Francisco, Hot Springs, Ark., Fort Bayard, N. M., Manila, Hawaii, and Panama.

The service at these hospitals is organized just as is the service at large civil hospitals. Medical officers according to their special qualifications, are detailed as internists, surgeons, laboratory workers, neurologists, oculists, aurists, and for other special services. The material upon which they may demonstrate their ability is ample. As noted above the government equips these hospitals with all the latest devices in medicine and surgery, and a complete library embracing all the latest medical books and journals is maintained at each post. Every opportunity and every facility is given the medical officer for research work and development and especially is this so in laboratory work. There has recently been organized in the Medical Corps a Research Division, composed of men possessing special ability and training in laboratory work, who will be given every opportunity for original work.

The opportunities for professional work and the standard of that work existing among members of the medical corps to-day is shown by what that corps has accomplished in recent years. It is well known how yellow fever was made to disappear from Havana and how the building of the Panama Canal was made possible by General Gorgas, an army surgeon. It is not perhaps so well known that typhoid, long the scourge of armies, has been entirely banished from our army by the work of Major Russell of the medical corps. Before the taking over by the United States of Porto Rico in 1898 smallpox and hookworm were the scourges of that island. Both have been completely abolished by the work of army medical officers. A similar tale may be told of the Philippines where smallpox and beriberi, the curses of those islands, no longer exist. These are but a few instances of the work possible for army medical officers. As a body they have big work provided for them and they always do it well.

An especially important branch of the medical officers' work is hygiene, sanitation, and preventive medicine, and in this work it is believed that the medical officers of the American army excel those of all other armies. In a recent letter from an army officer abroad, the following statement was made: "I have seen the field sanitation of most of the armies in Europe and I also had the pleasure of visiting the maneuver division of the American Army at San Antonio, Tex., in 1911. From what I saw there and from what I see here I am of the opinion that the American army beats the world in field sanitation."

In order that medical officers may keep abreast of what is being done in civil life they are encouraged in every way to associate with the leading practitioners in the vicinity of their stations and are *ipso facto* members of the American Medical Association. In addition to this they are usually given honorary membership in local societies wherever they may be stationed.

To give selected medical officers opportunity to see the work of the leading civilian physicians and surgeons, they are frequently detailed as attending surgeons in the large cities where they will have all the clinical advantages offered by the large civil hospitals.

So much for the purely medical side of the army doctor's life. In addition to this he must be a medical *officer*. That is he must be specially trained in the application of modern medical and surgical science to the needs of the military establishment. To this end he must be well-versed in military customs and the administration of the various sanitary units which go to make up the organized medical service of the modern army. The reason for the maintenance of this organized service in all armies is the preservation of the available fighting strength by the prevention of disease; and the cure and prompt return to duty of as many wounded as possible. To attain this end the medical officer has different and even greater responsibilities than his civilian brother.

What is the social side of the medical officer's life? What comforts may he expect and what hardships may he have to undergo?

In the first place he is a commissioned officer with the rights, privileges, and responsibilities that all other officers assume. He is in command of the enlisted force of the medical department and his life, character, and deportment must be such as to inspire confidence, respect, and affection from the men under his command and from his brother officers. In time of peace he must remember that he may at any time be called upon to undergo the physical hardships of a campaign and for that reason he must at all times, by means of exercise and the proper rules of living, keep himself in good

physical condition. This fact is recognized in armies and ample opportunity is afforded for exercise of various kinds such as tennis, golf, walking, riding, etc.

While on duty at a post he is furnished a comfortable house commensurate with his rank and his needs, and an allowance is made for heat and light. The commissary store of the Quartermaster Department furnishes necessary food supplies for the enlisted men and these may be purchased by officers at government rates by which a considerable saving may be effected in "the high cost of living." When on duty in cities where no army quarters are available, he is given commutation for quarters in accordance to his rank and is permitted to rent where he pleases. The general social life of an army post is that which one finds in any community of educated, well-bred people. One may enter into it as much or as little as he pleases, as military life does not mean the restriction of personal liberty.

The above is a brief outline of what the medical officer may expect in time of peace.

What may he expect if war occurs? In war the medical officer's place may be with the troops on the firing line, in the mobile medical organizations directly behind the firing line, or in the base and general hospitals well to the rear. In accepting a position in the medical corps he obligates himself to go wherever his services are needed. This may mean that he will have to spend weeks or months in camp and days on the march; that he may have to stand in the trenches beside the machine gun or that he may have to stand at an operating table in an improvised hospital day and night until exhausted; that he may have to sleep under a tent and live on the simple fare of the soldier. In other words that he may have to face war in all its stern realities. If he is not prepared to do this he should not enter the medical corps.

The following in detail are the requirements and the rewards of the medical officer:

Applicants must be between the ages of 22 and 32 years, must be graduates of recognized medical colleges and have had at least one year's hospital training. After passing a preliminary physical and mental examination they are commissioned in the medical section of the Reserve Officers Corps and ordered to Washington for a term of instruction at the Army Medical School. The course at this school is an excellent one and embraces the professional, medical, and military duties of the medical officer with a special laboratory course covering the essentials of field sanitation and hygiene. While attending this course they receive the pay of a first lieutenant, $166.66 per month and an allowance for house rent, heat, and light amounting to approximately $45 per month more. This will provide all the living expenses ordinarily necessary for a sojourn in Washington.

Upon completion of the school course, candidates are given a final examination and, if successful, are commissioned in the Medical Corps with the rank of first lieutenant. After five years' service, upon passing another examination, they are promoted to the grade of captain. Further promotion to the grades of major, lieutenant-colonel, and colonel are made by seniority. With the great increase in the regular army during the next four years, as now provided by law, promotion above the grade of captain promises to be fairly rapid.

The pay for the respective grades is: Lieutenant, $2,000 per annum; captain, $2,400; major, $3,000; lieutenant-colonel, $3,500; colonel, $4,000. ($150 per year is allowed a captain or lieutenant if he owns one horse, and $200 if he owns two horses. Forage is furnished for the horses.)

This is the flat pay, and the lower grades are increased 10 per cent for each five years of service up to twenty years. Thus a captain promoted after five years' service would receive in place of $2,400, 10 per cent. increase or $2,640 (if he owned two horses his pay would be $2,840); and a major after fifteen years service would receive $3,900. The ultimate pay in the higher grades is: Major, $4,000; lieutenant-colonel, $4,500; colonel, $5,000.

In addition to the flat and longevity pay each officer is allowed a house or when at a station where no public quarters are available, "commutation for quarters." This commutation amounts to $36 per month for lieutenants; $48 for captains, $60 for majors, $72 for lieutenant-colonels, and $84 for colonels. Where heat and light are not furnished in kind, an additional money allowance is made to cover the cost of same.

When their services can be spared, all officers are allowed one month's leave every year on full pay. Or the leave may be allowed to accumulate and they may be granted four months' leave at one time. Under exceptional circumstances officers may be granted a longer leave on half pay.

Having considered all the facts relative to the medical officer's life in detail, we are now prepared to answer the questions the graduate asked himself when he contemplated taking the army medical service as a career.

What may he expect financially? He will receive a moderate amount of pay but this pay is a certainty and he will receive it regularly sick or well as long as he lives. It will be sufficient to enable him to live comfortably and is in reality much more than a similar amount would be in civil life for the reason that he has no house rent and no office rent to pay nor does he have to buy the instruments, dressings, surgical material, and apparatus, as well as the books and periodicals which make so great a drain on the resources of the civilian doctor. Nor does he have to lay by a certain amount "for a rainy day." His retired pay attends to that. Considering all these facts the pay of the medical officer compares favorably with the average income from private practice.

What may he expect professionally? If he so elects he will nearly always have plenty of time and material for practising and advancing himself in his chosen profession; and time and opportunity for original study in any line he may choose.

What may he expect in his social life? He will always be able to live comfortably and will be associated with educated people both in his own profession and among the officers of the line and their families generally. He will be saved the annoyance and petty worries incident to competition and the seeking of practice in civil life. And he will have time to travel if he so desires without feeling that he is neglecting his practice.

Such then is the usual life of the army medical officers. As a whole the army is proud of them and the profession at large has given frequent instances of the regard and esteem in which they are held by their civilian brothers. Taking it all in all, it is believed that the Medical Corps of the Army offers a most attractive career to the earnest young doctor who is interested in his profession and does not yearn for large financial returns.

RETROSPECTIONS, MEDICAL AND OTHERWISE.

By A. D. ROCKWELL, A.M., M.D.,

FLUSHING, N. Y.

NEUROLOGIST EMERITUS TO THE FLUSHING HOSPITAL AND DISPENSARY.

In glancing over the earlier issues of the MEDICAL RECORD I find that it was in the year 1866, just half a century ago, that I wrote my first article in relation to "Electricity in Medicine," and in the flood of following years, nearly two generations have come and gone. As I find myself, after all these years, very much out of the race of active workers, yet sound in mind and body, with abundant leisure for the things I find most agreeable to do, it occurs to me that a few observations, personal and otherwise, and especially along the lines of my life work, might be fittingly given.

Since those days of crude appliances and crude and limited workmanship, electrotherapeutics has developed into a magnificent field of actualities, and still wider possibilities. Why the profession at large yet fails adequately to appreciate its value I will not attempt to say. One drawback, however, as I think all must agree, is that there has been by far too much special pleading, with all the hurtful influence on the professional mind that such enthusiasm implies.

Truly, it is the day of young men. The old clergyman is not very much wanted, neither is the old doctor, and so it comforts me to recall the reply of the ancient warrior to the boasting young brave that "the seventies have all the twenties and forties in them." The years during and immediately following the civil war did not hold much of scientific or original advancement in affairs medical. The surgery in the field was hasty and crude and preventive medicine practically unknown. It was before the birth of antisepsis and for lack of it men then died like sheep. There were not wanting, however, some keenly observant students, and among others, Weir Mitchel did useful and original work in the study of gunshot wounds.

The conflict over, a million young men were seeking a career, and many chose the profession of medicine. Two lecture seasons with no preliminary examination was the prescribed course, and in eighteen months young soldiers found themselves transformed into young medicos. My own medical training was little better, since I had graduated during the war and my experience as a surgeon through two severe campaigns, while extensive and varied enough, was of but little practical value. I recall with pleasure, however, that the most immediately useful asset in the field that my brief course at Bellevue gave me, was the private instruction in bandaging by the now venerable Dr. Stephen Smith, whose long life has been a pattern of efficient work. And very much I stood in need of further instruction, as the following incident illustrates:

On returning to civil life I put out my sign in Harlem, then a growing village, and while awaiting patients attended a third course of lectures at the College of Physicians and Surgeons, then located at Twenty-third Street and Fourth Avenue. I had never witnessed a case of parturition. When, therefore, my friend, the late Dr. E. Darwin Hudson, himself, later an expert, asked me if I would assist in taking charge of a case in one of the poorer purlieus of the city, I readily consented. Hudson was in the graduating class and to its members the professor, the late Dr. T. G. Thomas, occasionally assigned cases of this kind. Hudson, too, had never seen a case and in some trepidation he turned to me for aid. I was a graduate of some years; I had been an army surgeon. Surely here was a young man with large experience and one upon whom to lean in an emergency. It did not occur to him, and I did not refer to the fact that with an army in the field there was scant need for the services of an obstetrician. We found the suffering woman on the top floor of an old tenement, and entirely unattended. The only furniture of the room was a rickety bed, one end of which broke down during the accouchement, a wash bowl half filled with dirty water, and an old chair. I made the usual preliminary examination which afforded me no information, but I looked wise, and so far as I could see or feel pronounced everything ship shape. The hours passed drearily and wearily away and seeing no signs of an immediate ending, we withdrew for awhile to the old Earle's Hotel in Grand Street for rest and refreshment. Returning in the course of an hour and making another examination, I became puzzled and ill at ease. Feeling the great responsibility, Hudson went off in all haste to the residence of Dr. Thomas to report and for instructions. In due time he came back with word from the professor that everything was probably all right and suggested "patient waiting." In the early hours of the morning, a new soul was ushered into this waiting world. We washed and with the few rags found dressed the babe and went our way. What of the life and career of that boy? If still living he would be fifty years of age. Born in abject poverty, even in filth and disgrace, like another Oliver Twist, what chance had he? A victim of inexorable fate if he lived, let us hope that kind nature soon took him to herself.

During my brief but not altogether uninteresting experience as a general practitioner, I was called one day to see a woman evidently suffering from an inflammation of the brain or its meninges. All her life she had been a deeply religious woman and of exemplary character, and yet in her ravings she indulged in language both profane and obscene, rarely equaled by the most depraved natures. To me it is still a mystery how such a perversion found lodgment and outward expression in one whose nature was gentle and whose training and associations had been unexceptionable. During the evening a friend came in to see her. His name was William Miller, Dr. Miller by courtesy. I had already heard of him as a so-called electrician and knew that he received considerable patronage from some of the best men in the profession, among others Dr. Willard Parker. I found him a simple hearted old man of about 65 or 70, who had a great opinion of the value of electricity in the treatment of disease, and in the case at hand, with modesty and hesitation he expressed the opinion that a good strong application of electricity might do good. I was amused by many of his absurdities of statement, but was impressed by his evident honesty and by his large, yet crude and ill-digested experience, and naturally desired to know more of his methods in a field at that date so little cultivated by the profession. Fifty years ago it was a gala time for quacks of every description. Quacks for the ear, eye, and nose, as well as electrical quacks abounded, but this old man was good and honest and, as much as any one I ever knew, gave a quid pro quo for the little fee he received.

I accepted his invitation to come to his office at 914 Broadway to study his cases and see him work. I saw evidences of the good results that followed his stereoptyped and simple method of application, for his sole apparatus consisted of an ordinary induction coil constructed by himself, which, however, yielded a current of remarkable quality. He was intelligent, but unlearned. He knew nothing of electrophysiology and kindred departments, little of disease, pathology, or practical therapeutics. So far as conerns scientific electrotherapeutics, he existed as an example of profound ignorance, associated with perfect honesty of intention. He never enunciated an idea, neither had he any conception of the principles on which he worked or through which he wrought cures. He was, however, so thoroughly the master of the methods he invariably used that the truth of the saying that it is not so much the method that does good as the way it is employed, never seemed so clear as when comparing his effective manipulations with awkward slipshod methods. In many of his cases, unquestionably, the excellent results that followed were greatly aided by his powerful and skilful manipulating processes, which for all practical purposes was an expert and thorough massage.

About this time I renewed a former acquaintance with Dr. George M. Beard and he was greatly interested in my account of this old man with his novel methods and quaint ways, and together we both visited him again and again. Here, indeed, was something new and worth investigating.

During all my medical training I do not recall that electricity was ever mentioned in connection with therapeutics or even surgery. All other physical agents, water, air, exercise, heat, and cold received due attention, but Nature's most subtle, all pervasive, and most powerful principle remained absolutely neglected in this country excepting by dishonest empirics and a few eminently worthy but ignorant irregulars, like our good friend "Dr. Miller." Abroad, as we learned later, a number of able men of science had given the subject careful study, but as yet their investigations had made little impression here. It seems that already Beard with his usual curiosity in regard to every strange and misunderstood or ill understood thing, had in the past been somewhat interested in the subject.

While still a student at Yale, he had in his own person, experienced some benefit from the use of the crude induction coil. He was therefore quite ready to cooperate with me in my proposed investigations. After two years of working and waiting, I was beginning to get a foothold in Harlem and it required some little resolution to burn my bridges, as it were, and enter a new untried and unpopular field. Even that great and liberal minded man, Austin Flint, advised me not to meddle with it, but to leave it in the hands of the quacks where it belonged, while my equally good friend, Dr. Willard Parker, gave me similar advice. And then again, as young men will do, I had just become engaged and needed more than ever to get firmly established. To be sure, the income for the year had been somewhat under $1,000, yet it seemed to me fairly satisfactory and a precursor of future gains. And still again, it was somewhat unconventional and perhaps a little risky to become in any way associated with one who, however honest, was in the eyes of the profession little better than a quack.

After due reflection and consultation with Beard I removed my sign in Harlem as a general practitioner and rented a room in the same building with the office of Miller. In this way I had the advantage of studying his cases and at the same time getting some of the overflow. The profits were not very large, for Miller received the munificent fee of one dollar, and I could not well charge more. When it is remembered, however, that his daily patients numbered between twenty and thirty, it is seen that he enjoyed a comfortable yearly income. An amusing incident occurred in connection with this subject of fees. In the beginning of his irregular practice he charged but fifty cents a visit. Miller was a school teacher originally, and being of a mechanical turn of mind, became interested in the subject of induction coils. He began to treat people of his acquaintance for some of their ailments. By degrees his practice grew, so that he made a business of it, and finally acquired a wide clientèle. I suggested that he raise his fee to two dollars and pointed out the fact that one of his old patients about to come to him again just then was well to do, and a good one to begin on. With some hesitancy the old gentleman consented. She, upon whom the experiment was to be tried, came at the appointed time, received her treatment and handed the doctor the usual fee. With some embarrassment he said that he had raised his fee to two dollars. The richly attired patient surveyed him curiously for a moment and thrusting the bill into his hand said, "Go 'long, take your money." The doctor took it and that was the last attempt to raise his fee. Most of my practice, however, was unremunerative, excepting as it added little by little to the sum of my, or I should say our, experience.

Beard, to be sure, did not have his sign up, but he was as deeply interested as was I, and might be called a silent partner. He was at this time connected with the Demilt Dispensary, and it was his function to send as many of the charity patients as possible to 914 Broadway for electrical treatment, and experimentation. And to this day it excites a smile as I again see Dr. Beard with his grave face yet keen sense of humor, ushering into the little office half a dozen more or less of the unwashed. In one way we earned all the experience that came to us, since it was no pleasant job to go over the bodies of these unfortunates, especially in very warm weather. It was a crude experience, but we saw all manner of cases and of course kept a detailed account of each.

Dr. Miller was getting old and seriously thought of abandoning his work, and suggested that we give him notes for a certain sum, for the good will of the business. I suggested that he stay away from the office some day, and let me manage the patients that came. Alas for human expectations! On reaching the office that morning, I found half a dozen patients in waiting. The situation was explained, but without exception, one by one, they all departed leaving me alone, and of the more than twenty callers that day, not more than one or perhaps two cared or dared to trust themselves in my hands. That settled in my mind the question of the feasibility of buying a practice.

By this time, our experience had become such that we decided to give it to the world and selected the MEDICAL RECORD through which we hoped our views might be disseminated. The result was a series of five articles, running through a period of two or three months, under the title of "The Medical Use of Electricity." We had great hopes, for

we felt very sure that nothing quite like these papers had ever before appeared, but the results exceeded our expectations. The London *Lancet* republished each article as it appeared, and in Germany also they were reproduced. When finally William Wood & Co. issued the combined articles in book form, its reception was in the main highly complimentary. There were, however, a few discordant notes. Among these, the *Edinburgh Medical Review* was both humorous and unappreciative.

In making applications of the faradic current to sensitive parts, we explained the method of applying it through one's own person. No artificial electrode could equal the hand in flexibility and power of adaptation to inequalities of surface and in treating delicate women and children and in applications to the head, forehead, eyes, face, and sensitive motor points, the use of the hand was invaluable. In making use of this method we had observed that the muscles of our own arms had perceptibly increased in size and strength. In commenting on this statement, the *Review* went on to say, "Notwithstanding this alarming condition of affairs (the enlargement of the biceps) in consideration of the fact that the Atlantic ocean rolls between them and us we shall not hesitate to express our opinion."

About this time we wrote another joint article and sent it to Albany for the coming session of the State Medical Society. On the committee was Dr. S. of Brooklyn. Reading the title of the paper he quickly exclaimed, "What, are these men regular?" and if it had not been for minds more hospitable, it probably would have been rejected. Soon after, we conceived the idea of presenting the subject in Brooklyn. I mentioned the matter to that great and liberal minded man, Prof. Austin Flint, Sr., professor of the practice of medicine at Bellevue. "Certainly," he said, "I think you should do so; it is a subject of which the profession knows little or nothing, and I will give you a letter to my friend, Dr. S." Armed with this letter in which I was called "his young friend," I found Dr. S. in his office and handed it to him. He received me coldly and, having read it, gave it back, with the remark that he had little to do with that sort of thing, and said I had better call on Dr. R., as it was more in his line. To Dr. R. I went, and was well received. He expressed great willingness to give me an opportunity and said he would present the matter to the society and would communicate further with me. When he did broach the subject it was immediately met by opposition and the chief opponent was Dr. S. His objections were that the question of electricity in medicine was one in which they could have no interest, since it was little less than quackery; that the young man's chief aim was to drum up practice, and finally they needed no information from him.

Years after I did read a paper before this society by invitation. By this time the esteemed and in many ways excellent Dr. S. had long been in heaven and so missed the opportunity of hearing it. Patients now began to come to us in greater number, referred mainly by members of the profession who had read our contributions, had faith in our integrity, and saw the reasonableness of our contention.

About this time Dr. Beard received an independent commission from Scribner the publisher, to rewrite a great volume on Domestic Medicine entitled the "Home Physician." He entered upon the task with his customary enthusiasm and dogged industry and in an incredibly short space of time it was completed. Some would have placed at least a part of the fairly generous sum received in the bank for a rainy day, but this was against the principles of Beard, from which he never deviated to the day of his death. For him money was a thing not to be hoarded, but to be spent, and he therefore immediately announced his intention to go abroad. For certain very good reasons I objected but he persisted, saying, with much truth, that in visiting men of science abroad and especially those interested in the work in which we were engaged, he would garner much material that would be of service in the writing of the more comprehensive treatise that we were contemplating and later on accomplished. He was gone three months. When he bade me good-bye, I was treating a patient. When he returned and unexpectedly entered the office, that identical patient was seated on the stool, undergoing treatment. With uplifted hands and feigned astonishment, Beard exclaimed, "For the Lord's sake, have you been treating that man all this time?"

Beard brought back some valuable information, but of the $800 he took with him he had but fifty cents left, and none coming to him. The complications that ensued and how he managed to surmount them is another story.

Dr. Beard was a truly unique and attractive personality, but his name is now little more than a memory, and to allow my pen to linger for a while upon his gifts and graces would be an agreeable task. He coined the term Neurasthenia, and his classic monograph on the congeries of symptoms to which he gave a local habitation and a name was the basis of all subsequent literature on that subject. To his keen and discriminating examination, hypnotism yielded some of its mysteries, and he exposed the fallacies and unreliability of the average human testimony as few have done. His contributions to the subject of seasickness were original and of positive value, and he who reads his forgotten treatise on "American Nervousness" will find in it much truth stamped with his own individuality. His monographs on the "Legal Responsibility of Old Age" and the "Relation of Old Age to Work" still interest me, as do others of his many contributions outside the realm of actual medicine. He died at the age of 42, and as was said of the poet Burns, so almost may it be said of him. "The plan of a mighty edifice had been sketched, some columns, porticos, firm masses of building stand completed; the rest more or less clearly indicated with many a far-stretching tendency, which only studious and friendly eyes can now trace towards the purposed termination. For the work is broken off in the middle, almost in the beginning, and rises among us, beautiful and sad, at once unfinished and a ruin."

It may be all a fancy, but the great physicians of those days seem to loom up larger than those of this generation. There were the consultants, Alonzo Clark and Austin Flint, brainy and big physically, and who in relation to their fellows seemed in a way to stand apart. Among the surgeons were Parker, Sands, Van Buren, and Wood, and the gynecologists, Sims, Emmet, and Thomas, constituted a trio of surpassing excellence and originality.

The distinctive impression made by these men and a few others in this city and throughout the country may be accounted for in part by paucity of numbers. In the field of literature it is the same,

and the rule applies also to our estimate of great commanders in all wars previous to the unspeakable one now waging. So wonderfully has medical and surgical proficiency progressed that now the "woods are full" of men whose knowledge and skill are equal to every emergency.

But let us not forget the original minds that, preceding us, made possible the triumphs of the present. How in gynecology, as a single example, did the discoveries of a Sims revolutionize it! His statue stands in Bryant Park, unnoticed by the hurrying crowd, but the women of the world have cause to bless his name forever.

370 Sanford Avenue.

EXTRAUTERINE PREGNANCY.

By E. MAC D. STANTON, M.D., F.A.C.S.,

Schenectady, N. Y.

Compared with most of the other intraabdominal diseases treated by the surgeon, the problems presented by extrauterine pregnancy are relatively simple. For this reason we find that the first surgeon to deal with this disease—Lawson Taite—was able to master its essentials and place its surgical treatment on a foundation which has not been essentially altered since his time.

Because the problems of diagnosis and treatment are relatively simple, this disease should be to-day probably the best diagnosed and best treated of the intraabdominal surgical conditions. That this is not always the case, however, is indicated by the fact that my records show that just one-half of the patients referred to me with extrauterine pregnancy had been previously treated for from a week to several months under a mistaken diagnosis, and seventeen per cent. of them had been previously curetted for supposed abortions. In all but one of the orginally incorrectly diagnosed cases the essential points were present in the history which should have led to at least a presumptive diagnosis when the patient first consulted her physician. In the one exception an attempted criminal abortion so beclouded the history as to make a diagnosis before the tragic stage quite unlikely.

That the disease is not so rare as to give the general practitioner an excuse for failing to bear it in mind is shown by the fact that nearly two per cent. of my laparotomies have been performed for this condition. With such a record as to diagnosis in a community like Schenectady, filled by a group of practitioners whose diagnostic skill I know to be fully equal to, if not above, the average, I am led to believe that certain of the main points concerning the diagnosis and treatment of this disease will once more bear reiterating.

Etiology.—Up to the present time no really satisfactory hypothesis has been advanced to account for the fixation and development of the ovum in the extrauterine position. It seems futile to offer theories for these abnormal cases when we know almost nothing of the forces which carry the fertilized ovum to the uterus and fix it in its normal habitat.

Most writers have emphasized the fact that a large percentage of ectopic cases give a history of a preceding period of sterility often accompanied by symptoms referable to a pelvic inflammatory disease. This same fact was noted in a considerable proportion of my own cases, but it is by no means an absolute rule, and its importance should not be overestimated. Williams[1] states that in seventy-nine cases studied by him the average period elapsing between an intrauterine pregnancy and the subsequent extrauterine pregnancy was three years and nine months, or but little more than the average to be expected between normal pregnancies.

Diagnosis.—In considering the diagnosis of extrauterine pregnancy it is well to follow the plan of grouping the symptoms into those of the "tragic" and "non-tragic" stages.

The classical case of extrauterine pregnancy in the "tragic" stage of the disease should be diagnosed almost at sight—a woman, an abdominal pain, and sudden pallor or collapse, are the three factors necessary for an almost positive diagnosis. The other data, such as suspected pregnancy, irregular flowing, the absence of a history pointing to a perforative ulcer, etc., may be obtained while preparing to carry out the steps necessary to bring the patient to the operating room in the best possible condition. A bimanual examination is not necessary, and, as a rule, one should not be made until the patient has reached the operating room.

It must be borne in mind, however, that the tragic stage is seldom the one first encountered even by the consulting surgeon, and the general practitioner really sees very few cases for the first time in this stage of the disease. Harris[2] has reported a series of one hundred and thirty cases in which more than ninety per cent. of the patients first presented themselves for examination before the tragic stage. My experience is in accord with that of Harris, in that all but two of my patients consulted a physician for trouble due to the extrauterine pregnancy at a period previous to the onset of the tragic symptoms.

The Non-tragic Stage.—In the non-tragic stage the diagnosis is not forced upon one as it is in the tragic cases, and yet in nearly every instance the data necessary for an almost positive diagnosis may be elicited from the history alone. Additional data may often be obtained from the physical examination, but if the objective findings are not of a very positive character, either for or against the diagnosis, they are liable to prove misleading, and should be rated as of secondary importance to the data obtained from the history.

The two symptoms of paramount importance in the early diagnosis of ectopic pregnancy are pain and irregularity of menstruation. Harris says: "When any woman, after puberty and before the menopause, who has menstruated regularly and painlessly, goes 4, 5, 6, 8, 10, 15, or 18 days over the time at which menstruation is due, sees blood from the vagina differing in quality, color, quantity or continuance from her usual menstrual flow, and has pains, generally severe, on one side of the pelvis or the other, or possibly in the hypogastric region, ectopic gestation may be presumed."

In my series, without exception, it was pain which first caused the patient to seek medical advice. In each case, either the first or some of the following pains were typical or highly suggestive as to character if not as to location. Usually, but not always, they were quite severe. There may have been dull pains and laborlike pains, and pains such as the patient has during her menstrual periods, but some time in each of my cases at least one or several pains were experienced which were sharp and quick in character, and quite unlike those ordinarily encountered in other pelvic conditions. "Sudden," "stabbing," "knifelike" are terms often used by the patients in describing these pains.

As a rule, the pain is located in the pelvis, but,

curiously enough, it may be referred by the patient to the back, rectum, epigastrium, or kidney region, so that it may require close questioning to locate the trouble in the pelvis. As a rule, nausea rarely accompanies pain of pelvic origin, but in my histories I find frequent mention of nausea, or even vomiting, in relation to the sudden pains of extrauterine pregnancy. Fainting is usually a symptom of the tragic stage, yet more or less faintness is frequently mentioned in my histories, even without marked evidence of internal hemorrhage.

Irregular Flowing.—The expression, "a typical menstruation of ectopic gestation," although a misnomer, is a useful one in so far as it directs attention to the appearance of blood, in time or character of flow out of rhythm with the normal menstrual cycle of the individual. In two of my histories the record as to menstruation is incomplete. In each of the other cases there is a definite record of irregularity. In some a period had been missed but bleeding varying from a slight show to rather severe hemorrhage came on just before or soon after the onset of pains. In several cases both the pains and show began soon after an apparently normal period.

It has been shown that the continued uterine hemorrhage so frequently encountered in these cases usually commences with the death of the fetus and continues while placental tissue remains in contact with the tube, the physiological factors responsible for its continuance being essentially the same as in an ordinary incomplete abortion. Even in those rare cases when the life of the fetus continues, more or less uterine bleeding at irregular intervals is the rule.

The really important point to be always borne in mind is that pelvic pain plus an unusual uterine bleeding spells ectopic pregnancy, in a very considerable proportion of cases. Whenever this combination of symptoms is present it becomes the imperative duty of the practitioner to rule out the possibility of extrauterine pregnancy before proceeding to entertain any other possible diagnosis.

Additional diagnostic data may be obtained from many sources. In the pretragic stage there is seldom any elevation of temperature commensurate with the amount of acute trouble evidently present in the pelvis. On the other hand, I have myself several times erred or come near erring because I did find a temperature of from 100° to 101° or even higher, and we should always remember that intraperitoneal hemorrhage is usually followed by a fever of the surgical type.

Treatment.—In no other field of abdominal surgery were the advantages of operative treatment so promptly recognized. The excision of the appendage bearing the gestation sac is usually a very simple procedure, and except for the acute anemia and shock encountered in the tragic stage these patients are usually excellent operative risks. A good deal has been written about the advisability of delaying operation in cases of profound collapse. I am a firm believer in delay if the patient is in such collapse as to be obviously unable to stand any operation, but I do believe the fact should be very strongly emphasized that extrauterine pregnancy patients in the "tragic" stage of the disease stand anesthesia and operation better than any other cases presenting like blood pressure and pulse findings. The man reduced to an apparently similar state of collapse or shock by a traumatism such as a crushed leg is in no way comparable as an operative risk to the woman suffering from a ruptured ectopic, and the same may be said of the shock and collapse accompanying perforations and intra-abdominal infections.

Nine of my patients were operated upon during the acute tragic stage in the presence of acute anemia and a rapid pulse. One I kept in a partial Trendelenburg position for about two hours before operation because she was quite pulseless when admitted to the hospital. Every one of my tragic cases actually improved from the time they began to take the ether until they left the operating table. The operations were complete in from seven to ten minutes. No time was spent in removing clots other than those which presented in the wound and pelvis during the manipulations necessary to excise the gestation sac. All of these tragic stage patients made uneventful recoveries. I know of no other pathological condition capable of producing the degree of "shock" present in these nine patients, for which I could operate in the presence of the shock without expecting a mortality of from 30 to 60 per cent.

When operating in the non-tragic stage, procedures other than the simple excision of the affected appendage may be safely undertaken. First as regards the removal of blood and clots, I believe that the peritoneal cavity should be left reasonably clean, but this does not mean that the intestines should be much handled and endothelial surfaces injured by sponging in over-careful attempts to rid the peritoneal cavity of blood. If the loops of intestines are not displaced and are left to normal relationship one to another the remaining blood will do no harm other than to cause a few gas pains during the first days after operation.

There has been considerable discussion concerning the danger of a second ectopic in the opposite side if both tubes are not excised. Statistics on this question vary so much as to make them of little value from a percentage viewpoint. They do show, however, that if the opposite tube is not removed the woman who has had one ectopic pregnancy stands a fairly good chance of having subsequent normal pregnancies and a rather remote chance of a second ectopic pregnancy. In my own work I have not felt it justifiable to remove the opposite tube because of the danger of a second ectopic, yet for one reason or another (usually because of obvious disease of the other tube) I have excised both tubes in eleven out of twenty-three operative cases.

Hysterectomy.—Recently, at least one surgeon of prominence has advocated removing the uterus in these cases. Such a procedure may yield interesting pathological data but otherwise the arguments in favor of hysterectomy are in kind like advocating excision of the toes for fear they might some day be frozen.

Drainage.—Unless there is oozing from granulating surfaces at the placental site it is seldom advisable to drain these cases even though considerable blood be left behind. In my series drainage was used only twice, each time because I feared oozing from a raw granulating surface.

Late Cases with Living Fetuses.—The above remarks concerning the simplicity of the operation have concerned the ordinary case interrupted in the vast majority of instances before the third month of the pregnancy. Occasionally an extrauterine pregnancy may proceed with a living fetus to a much later stage of pregnancy, or even to term.

In these cases, if the fetus be still alive, the problem of dealing with the broadly attached placenta without encountering terrific hemorrhage is very difficult. Unless one can be certain of being able to control the blood supply to the placenta in these cases it is best to remove the fetus and leave the placenta until it has had time to become separated from the maternal circulation. The older surgeons encountered a fair number of these cases but better diagnosis and prompt operations have made them so rare to-day as to have little influence on the subject as a whole.

Transfusion.—In patients suffering from the effects of acute hemorrhage, blood transfusion, using a properly selected donor, gives practically perfect results. Many cases of ruptured ectopic pregnancy offer ideal indications for transfusion. However, because of the possible dangers of anaphylaxis and the fact that insufficient time is usually available for the various laboratory tests of compatability, transfusion should be resorted to only when it is evidently so necessary as to make the risks incidental to the transfusion itself of but minor relative importance.

In my own work I have never had to transfuse an ectopic patient but in a number of cases of hemorrhage from other causes we have during the past year used the indirect 0.2 per cent. citrate method of Lewisohn.[3]

The technique of this method is so simple that it can be carried out by anyone capable of giving an intravenous transfusion of physiological salt solution and in our experience it has given perfect results. If the citrate solution and other apparatus necessary for giving one of these transfusions is not kept constantly on hand in the hospital, immediate arrangements should be made to prepare an outfit and provide a donor to be used if necessary at the time when the ambulance is called for an ectopic patient encountered in the tragic stage of the disease.

Prognosis.—There are no reliable statistics purporting to show the mortality in ectopic pregnancy cases before the days of surgical intervention. In those days the diagnosed cases mostly ended fatally or were first diagnosed at autopsy. The fact, however, that the disease was then looked upon chiefly as a rare pathological curiosity occasionally encountered by those doing coroner's autopsies would lead one to believe that a large proportion of those cases now operated upon as ectopics eventually recovered. Our present knowledge concerning the frequency of termination by tubal abortion would also tend to support this view.

To-day the advisability of operation is universally recognized and with average surgical skill the prognosis depends almost entirely upon the condition of the patient when she reaches the operating room. Surgeons are agreed that except in the worst of the tragic cases the mortality after operation is almost nil, and the after results are most satisfactory. In my twenty-three operated cases there was no mortality and there were no postoperative complications worthy of note. The one case dying under my care is reported as follows:

Female, age 30, referred by Dr. Murray. This patient had been ill three weeks with what I diagnosed as pelvic peritonitis. The temperature had ranged from 99° to 101°, and the predominating symptoms when I saw her were those of peritoneal irritation involving the small intestines. She was sent to the hospital with the intention of operating the following day, but by morning her condition was seen to be improving so markedly that the operation was deferred. Finally it was decided to operate the fifth day following her admission, but at 3 A.M. on the morning she was to be operated upon the patient woke out of sleep, raised up in bed, fell back gasping for breath, and died at 3:20 A.M.

Autopsy showed an extrauterine pregnancy with the tube adherent above the pelvic brim, the hemorrhagic mass being surrounded by loops of small intestines. Death in this case was due to an error in diagnosis which was, however, partially justifiable owing to the abnormal position of the tube. The clinical picture which had held my attention was always referable to the involvement of the small intestines in what I took to be an inflammatory process. Nevertheless, when the history of this case is reviewed with the idea of extrauterine pregnancy in mind the essential points for the correct diagnosis are found to have been recorded by myself at my first examination; namely, abdominal pain promptly followed by irregular flowing which was still present when I first examined the patient.

Cases Incorrectly Diagnosed as Extrauterine Pregnancies.—I have operated upon one patient under a positive diagnosis of ectopic pregnancy who turned out to have had a sudden rupture of a cocoanut-sized ovarian cyst. Two other patients I operated upon because of early pregnancy, severe pains, and what I took to be a mass at one side of the uterus. In both I found intrautreine pregnancies with the early uterine enlargement confined chiefly to one side of the uterus. Irregular flowing was not mentioned in the history of either case.

HELIOPHOBIA.

A MENACE TO THE COMMUNITY.

By F. ROBBINS, M.D.,

NEW YORK.

The obligation of the physician to set an example to the community is greater to-day than heretofore, because his personal transgressions against the laws of hygiene are apt to become common property in these days of general admission to medical societies and libraries. The physician who shuts out precious sunlight for hours from a reading room because for five minutes a ray has danced across his page, sets a pernicious example to the ever-present majority of the ignorant. *Praesente medico nihil nocet* is a sentence perhaps not intelligible to all readers, but the principle still survives in a community which is fast losing all reverence for the medical profession.

God said: Let there be light. The devil whispered to men, and blinds were invented. (According to the Century Dictionary, a blind is anything which obstructs sight, intercepts the view, or keeps out light; the associated meanings of the adjective are very suggestive: Not possessing or proceeding from intelligence; destitute of intellectual, moral, or spiritual sight.) It would be comical, were it not so serious a matter, that "blinds" is the term selected for the contrivances which begrudge the light to the other occupants of a room, in "favor" of the one or two who may be incommoded (not actually harmed) by the visiting sunlight. It is the old confusion between cause and effect. For the reassurance of those who honestly fear harm to their own eyes, and therefore feel justified in de-

priving others of their share of the sun, be it said that one of the most efficient treatments of trachoma is—sunlight. In the experience of Grönholm, a single exposure of the affected eyes to sun-radiation according to Finsen's method, during ten minutes, was sometimes sufficient for a cure. Very favorable results were obtained by Hunsel, in eighty cases of trachoma, by combining copper-sulphate treatment with daily exposure of the eyes to sunlight.

According to the Bulletin of the American Association for the Conservation of Vision, at least half of the educated class in the United States are afflicted with serious defects of vision, and the conspicuous reason for the present condition is the practically universal ignorance regarding the eyes, their care, and the way in which they should be used. It is of tremendous national importance, says Douglas C. McMurtrie, that the American people shall be endowed with good eyesight.

The greatest good to the greatest number involves full utilization of our none-too-abundant light from heaven. For those whose subjective sensations lead them to the unjustifiable exclusion of the sun's good light from places destined for the accommodation of others who believe in the preservation of sight through light, the individual adoption of smoked glasses (Schutzbrillen of the Germans) is recommended as the simplest and fairest solution of the glare-problem. The word "glare" is one recently adopted by the engineering profession from general usage, meaning discomfort or depression of the visual function, associated with strong light sensation. In his discussion of physiological points bearing on glare, Cobb points out the fact that detailed knowledge on this subject is scarce, and also that under practical conditions, the actual reduction of visual acuity by this feature of glare is not so great as to cause in itself serious embarrassment of vision.

The optic nerve is made to be stimulated by light. Normal eyes are rendered extremely sensitive to light through prolonged sojourn in the dark; the more so, the more carefully the light is kept away from the eye. In order to protect for minutes a pair of abnormally sensitive eyes, the heliophobe will cheerfully proceed to darken for hours an entire room, and incidentally to cultivate millions of bacteria. Safely encased in the impenetrable armor of egotism, he thoughtlessly jeopardizes the sight and health of his fellows, lowering blinds right and left for his personal gratification, without ever remembering on his departure to readmit the light of day. Once pulled down, a window blind remains down by common consent and indifference, in the great freemasonry of laziness. Libraries are not the only offenders, however, and public institutions such as post offices are open to criticism, if shuttered from the sunlight. The Fifty-first Street station in this city scrupulously excludes the sun from its southern windows, and gratuitously serves the public with a choice allotment of germs from all sources. Elevated railroad companies, while chary of giving full value in form of a seat for the nickel, generously provide shutters and blinds, which the conductor considers it a sacred duty to pull down on the sunny side of the train, ostensibly to protect the eyes of the reading public—(too bad anti-vibrators are not furnished at the same time!)—but really to provide a culture-medium for the vegetable and animal parasites which lurk and multiply in the shadows. Public health would be the gainer, were the exclusion of sunlight (a most efficient germicide) from public conveyances declared a misdemeanor.

The commercial spirit of the age manifests itself very plainly in the disregard and waste of sunlight. Although the sun still shines for all, unless prevented by skyscrapers or blind-pullers, the formation of a sun trust in years to come may serve as an eye-opener. Many patrons of window blinds have never heard of the heliotherapy of tuberculosis, nor do they realize that the scientific exploitation of sunlight may yet be developed into a close competitor of radium and the *x*-ray. Millions are expended for radium-treatment of cancerous skin-growths before the purposeful application of direct sunlight has been given even half a trial. Rain water warmed by the sun was credited with cardinal virtues for the tubbing of delicate babes in the old-fashioned nursery. The up-to-date boudoir is beginning to be interested in "radiumized" water, for Milady's, or perhaps for Fido's bath. *Mundus vult decipi, ergo decipiatur.* Revel in radium, if you will, but *do not rob* your neighbor of the sun!

What is the basis of this irrational attitude towards sunlight, and of the fear of its effect upon the eye? Answers of habitual blindpullers vary from the naïve, "It hurts my eyes," to a more sophisticated reference to the "injurious" ultra violet rays. Let us see. According to available measurements, the rays which reach us from the sun correspond to wave lengths of about 50,000 to about 100 μμ. Wave lengths of about 810 μμ to about 380 μμ belong to the visible spectrum. Invisible rays of more than 810 μμ are designated as ultra red rays, while rays of less than 380 μμ are usually described as ultra violet rays. It has been shown that rays of shorter wave length than 38 nn. are practically entirely absorbed in the cornea, so that these rays cannot possibly exert an injurious effect upon the lens and retina, but at most only upon the superficial portions of the eye, the cornea and conjunctiva. These short wave lengths are essentially responsible for the phenomenon of snow blindness, the changes of which are usually restricted to the conjunctiva. Concerning the injurious action of short wave rays on the endothelium of the cornea and on the crystalline lens, the interposition of an ordinary glass plate, such as window-glass, between the source of light and the eye suffices to prevent an injurious action on the endothelium. (Hess.) The contents of sunlight—even less so than those of artificial light—in ultra violet rays are not sufficient to cause eye-trouble. Persons who work daily in a strong artificial light, as in electric concerns, for example, suffer very rarely from ocular disturbances, except through negligence or accident. Under ordinary conditions of daily life, the ultra violet rays do not enter into consideration at all, in the protection of the eye against an alleged excess of light. At a low sea level, ordinary daylight contains very small amounts of ultra violet rays, which are absorbed to a considerable degree by the deeper air-layers. Moreover, as emphasized by Fuchs, the ultra violet rays are not perceived by the retina, and therefore cannot produce unpleasant sensations of any kind. The dazzling sensation caused by a glare of light is derived only from the visible rays of the spectrum, the same rays which are injurious to the eye in diseased conditions of the retina and chorioid. In all such cases, ordinary smoked glasses will protect

the wearer against all fancied or real danger, without interfering with the right and health of others.

In the presence of hyperirritability of the retina, even a small amount of bright daylight may elicit unpleasant sensations, and this is frequently the case in neurasthenic and hysterical individuals. Fuchs compares this intolerance of light with the equally common hypersusceptibility to noise, in nervous patients. People of this description are apt to complain not only of more or less brilliant daylight, but also of unpleasant sensations produced by bright or shining objects, for example, by the white paper, when reading or writing. In illustration, Fuchs mentions the case of an overworked and highly neurasthenic business man, who finally came to shield his eyes with his hand when signing his name, in order to avoid being dazzled by the white paper. In all probability, he had also contracted the delightful habit of lowering all blinds within his reach. Shrinking from bright daylight or sunshine is a very common sign of neurasthenia. The victims of drug habits, especially morphine, often insist upon the most rigid exclusion of sunlight from their shadow-realm.

The light of day has never been shown to have an injurious influence upon the eye, in health or even in disease, and it is an antiquated notion to hold strong sunlight responsible for certain forms of eye trouble. Such views were current in the eighties, and should long have been outgrown even by the laity. On the ground of biological considerations, as pointed out by Hess, it is difficult to conceive that a living structure, phylogenetically developed under the permanent action of daylight, should have simultaneously acquired the peculiar property of sustaining damage through this same daylight. In a lecture held at the international Medical Congress, London, 1913, Hess conclusively refuted the view that photophobia is transmitted by the nerves of the cornea and iris, for he showed that tight compression of the eyes, even in total darkness, after all light has been excluded, often relieves the disturbances in diseased conditions of the cornea and iris. As tight compression of the eyelids has the same effect also in the presence of light, the widespread misconception has arisen that the reason for this compression is photophobia. This misconception flourished on the adaptation of the eye to the darkness, through the partial closing of the lids, with the result that it becomes more sensitive to light. This fear of light is secondary, however, being caused by the palpebral closure, and is not related to the corneal affection as such. This arbitrary closing of the eyelids, and the resulting photophobia, is entirely analogous to the wilful drawing down of window blinds.

Darkness or a dim light plays a peculiar part in the psychology of the sufferers from heliophobia. The significance of darkness in nervous psychopathology was investigated by Abraham, who finds that this light-fear manifests itself in form of intolerance for daylight, more particularly sunlight. Psychoneurotics of this type are easily "dazzled," feeling their sight confused by brilliance of light. Some complain of more or less severe pain in the eyes on brief exposure to moderate daylight or artificial light, and resort to all sorts of measures for protection against it. Besides showing an exaggerated sensitiveness toward illumination, these persons react to light stimuli with a true phobia of the neurotic fear type. The subconscious content of the fear complex is threatened blindness. All psychoneurotics of this group suffer from heliophobia. A heliophobic patient under Abraham's observation hung threefold curtains before his bedroom windows, so that not a ray of light could enter in the morning. Psychoanalysis finally showed that the patient identified with the sun the watchful eye of his father, whose control he was anxious to escape. It would lead too far to enter into a consideration of the sun as a phallus-symbol. Let us plead, in the last words of Goethe, for "more light," and with a modern poet, Rhys Carpenter,

"Because we dare behold the sun,
With eyes unshaken, unafraid!"

TONSILLECTOMY UNDER NOVOCAINE.

By P. M. LEWIS, M.D.,

NEW YORK.

HOUSE SURGEON, NEW YORK THROAT, NOSE, AND LUNG HOSPITAL.

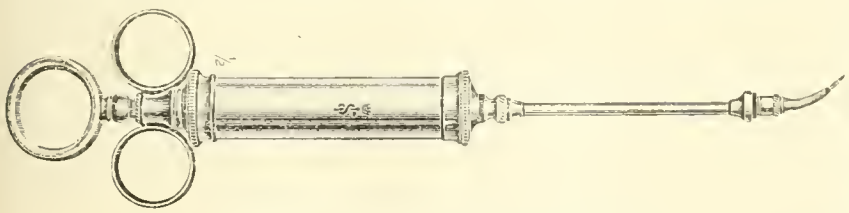
THIS article is written in order to relate a little experience regarding tonsillectomy as I found it in my own case. We often hear that there is no better way to learn than by veritable experience and so it is. We can apprehend and appreciate to a certain degree the subjective and objective symptoms of others, but when those symptoms are personal we can more thoroughly orientate ourselves to the real condition of things.

Having had several attacks of follicular tonsillitis in previous years and having lately seen so many pernicious maladies arising from pathological tonsils I resolved that it was very pertinent to have mine removed since they had several times proven themselves subject to infection. One attack of tonsillitis or the slightest focus of infection should be conclusive evidence in favor of their extirpation. The tonsils have been shown capable of being the host of many and varied forms of organisms from the non-pathogenic to those of the most virulent types. One cannot scrutinize too closely for some focus of infection. Frequently in removing an apparently healthy tonsil, products of inflammation will exude while manipulating the tonsil during the operation. The prominence or non-prominence of the tonsil offers no index as to the amount of hypertrophy or diseased condition. Some of the largest tonsils with marked pathological lesions are the so-called buried ones and may present a normal healthy surface as viewed intact.

When indicated, tonsillectomy should be done during childhood. At this period of life the tissues that will be cut and traumatized during the operation heal readily and the inconvenience to the patient lasts only a day or so; whereas in the case of an adult the tissues are highly fibrous, necessitating more trauma during the operation, the healing process is slow and the patient is quite conscious of a real sore throat for longer than a week. I am sure that most operators are aware of the fact that as age advances the period of convalescence from tonsillectomy increases.

Novocaine in tonsil work is advocated only in the case of adults and then the operator should use some discretion and satisfy his own mind that the patient is not of a highly nervous type and one that will give him a considerable amount of trouble during the operation. The patient should be given his choice between a local and general anesthetic and told the advantages and disadvantages of each. Some patients have a horror of being put to sleep and will welcome the suggestion of a local anesthetic. A patient's mental condition on a subject of this nature should not be ignored and where there is an alternative the mental equilibrium of the patient should not be perturbed.

The following are some of the advantages of tonsillectomy under novocaine: (1) If it be a clinical patient it is not necessary for him to remain in a hospital; he can go home alone and the probability of a hemorrhage is not nearly so great as in the case of a general anesthetic. The expense of an operating room, the necessity of an anesthetist and an assistant are eliminated. (2) The hemorrhage during the operation is insignificant and the postoperative hemorrhage is always slight. (3) The patient is in the upright position, which is the ideal position for the operator. (4) From personal experience I can give the assurance that the patient does not experience any pain. This may not be true in every case when the operator has failed to anesthetize the tissues properly. (5) The patient can hold the mouth open and it is not necessary to use a mouth gag or tongue depressor nor does one have to traumatize the tissues by sponging, for if there is any bleeding the patient can expectorate it.



Street's syringe for injecting the tonsils

Technique.—It is not the purpose of this paper to describe the technique of tonsillectomy, since that can be found in any standard text on the subject. It is only desired to describe the method of administering the anesthetic and the after treatment. The tissues surrounding the field of operation should have a thorough application of a 4 per cent. solution of cocaine and in a few minutes an application of a 10 per cent. solution of cocaine over the same area. The initial 4 per cent. cocaine is tolerated much better by the patient than if a stronger solution be used. The cocaine is used to allay the reflexes of the fauces and the pharynx. If this is not done the manipulation of the instruments during the operation, touching highly irritable tissues, will produce very annoying reflexes causing the patient to gag and retch even against his strongest voluntary efforts to resist. Then, too, when the tissues are partly cocainized, making the puncture to inject the novocaine will cause but little if any pain.

For the injection of novocaine, Street's syringe is conveniently used. The suitable size of the instrument with the needle curved at an angle of about 45 deg. to the long axis of the syringe add much to the advantageous use of it. In addition the guard around the needle extending to within a certain distance of the point will prevent the needle from making too deep a puncture. With everything prepared a 2 per cent. solution of novocaine with a few drops of adrenalin added is injected into each tonsil. The first injection is made in the most prominent part of the tonsil. While injecting the solution the tonsil is seen to swell and in a few moments become somewhat blanched. Novocaine being such an efficient anesthetic, and because of the great vascularity of the tonsil tissues the drug being so rapidly absorbed and disseminated throughout the area, probably the initial injection would be sufficient for the operation; but to be sure the anterior and posterior pillars and the edges of the tonsil should be injected. With this procedure one can always feel satisfied that the tissues are thoroughly anesthetized and can assure the patient that the operation will not be painful. Novocaine is being used frequently in our clinics for tonsillectomy with unique results.

Cocaine should never be injected into the tonsils, for it is very toxic, the tissues in that area rapidly absorb it, and several fatalities have been caused by its use.

Postoperative Treatment.—The following applies to tonsillectomy performed under a general anesthetic as well as local, especially in adults. In the case of a local anesthetic the patient will feel quite normal after the operation until the effects of the anesthetic have abated, which is from one to three hours. After this the throat will be extremely sore. The patient should not remain up any undue length of time. There is a decided hyperactivity of all the salivary glands. In addition to this phenomenon there is some bleeding, and with this accumulation of foreign material in the mouth there will invariably follow frequent attempts at deglutition. Even if the saliva and blood are expectorated deglutition will follow unless prevented by strong voluntary efforts. From the standpoint of hemorrhage deglutition is a most serious factor. With each deglutitory action, the levator palati, the tensor palati, and the palatopharyngei (posterior half arches) muscles in contracting to close the posterior nares will pull upon the tissues that have been cut during the operation, break up nature's barrier, and bleeding will start anew. The patient should be advised not to swallow any more than is absolutely necessary for the first twelve or eighteen hours following the operation. This advice is very difficult to follow. To aid the patient in this he should have ⅛ to ¼ grain morphine hypodermically. It is not the custom to follow tonsillectomy with morphine, but there is nothing to be gained by withholding it and it is of paramount importance for the patient to have it if for no other purpose than indirectly to prevent hemorrhage. It will make the patient more

comfortable, decrease the attempts at swallowing, and in this way guard against hemorrhage. Only one dose should be given and then only after the effects of the novocaine have subsided. When given, the patient should be told that he is getting something to prevent hemorrhage, which statement will be true and he will rarely know any better. Adults seldom have adenoids, but when present they should not be removed during the tonsil operation if it is done under a local anesthetic, for the bleeding from the adenoids will inconvenience the patient more than that from the tonsillectomy. Then the mucous membrane on the posterior tips of the turbinates may be abraded or enlarged posterior tips may even be cut off if the LaForce adenotome is used and the bleeding will persist for several hours. The adenoids can just as easily be removed at some other time.

After the danger from hemorrhage has passed, the patient should be advised to swallow the saliva that collects in the mouth and not to expectorate it. The procedure is quite difficult to the patient, but it must be done to keep the tissues of the back of the mouth and pharynx moist. At this period the tissues have a tendency to become dry and if they are not kept moist by swallowing the saliva they will remain dry and painful. The patient should know about these things and it will add much to his comfort. A weak saline solution used as a gargle will stimulate the secretions, aid in keeping the tissues moist, and be very soothing to the patient.

THE TUBERCULIN DISPENSARY.

By RICHARD COLE NEWTON, M.D.,

MONTCLAIR, N. J.

LATE CAPTAIN AND ASSISTANT SURGEON, U. S. ARMY; LATE PRESIDENT N. J. STATE BOARD OF HEALTH; CONSULTING PHYSICIAN TO NEW MOUNTAINSIDE HOSPITAL.

THE principal reason that we are making so little headway toward the stamping out of human tuberculosis is that there are so many unlocated incipient cases. Before we shall make real progress in this direction, the popular conception of the extent and true history of the disease must be entirely changed. The tuberculin diagnostic test must be generally adopted and some method must be devised by which practically all children and all adults whose systems are below par, without an obvious cause, must be subjected to the test; and those found to be infected must be treated, and that too, if possible, before positive symptoms can be demonstrated in the lungs or in any part of the body. When a positive diagnosis of tuberculosis can be made by physical examination of the chest, the case is no longer incipient, and the golden moment for beginning treatment has passed.

It may be a long time before wholesale tests with tuberculin will be made upon human beings as they are now made upon cattle. We have not yet reached that stage of civilization when human life shall receive as much consideration as property. Cattle must be tested for various diseases, including tuberculosis, and are carefully protected from infection by legal enactment. If they become infected and are therefore a menace to other cattle they must be instantly slaughtered if necessary to prevent the spread of contagion.

With man, conditions, of course, are different, and it is by no means entirely due to indifference that it is so difficult to bring incipient cases of human tuberculosis promptly under treatment. There are several reasons for this, the principal one being the widespread ignorance of the true nature of tuberculin, and the consequent fear that harm may result from its use. Nor can we justly assert that there are no grounds for this fear, if one may judge the present by the past.

Ever since Koch proclaimed tuberculin as a remedy for tuberculosis its use has been more or less a series of experiments which have been largely unavoidable owing to the peculiar nature of the remedy, and the natural history of the disease, neither of which have, as yet, been fully explained, although, fortunately, recent researches in biochemistry, immunity, and susceptibility have thrown so much light upon these intricate subjects that clinicians are moving forward in the treatment of tuberculosis with supreme confidence in the ultimate outcome of the warfare against this insidious enemy.

It has been absolutely demonstrated that tuberculin, in moderate doses, has no effect on non-tuberculous human beings, any more than it has upon healthy cattle. Furthermore, it is not a poison, and when properly used does no harm to tuberculous subjects in any stage of the disease. It is, in reality, a measure of their susceptibility, and in properly graduated doses calls forth the protective agents of the body in increasing numbers until the patient becomes completely immune to the tuberculin, which contains the most active agent of the tubercle bacilli. (The bacilli, however, from which the tuberculin has been extracted, have all been killed by heat and the product has been filtered through porcelain before being put upon the market. It has also been accurately standardized.) The tuberculin calls forth an artificial immunity in the body, which strengthens and reinforces the natural immunity which is possessed in some measure by every one, and in this way affords an escape from the infection of tuberculosis.

When these fundamental facts shall be generally understood the further information must be disseminated that practically every one is tuberculous at some time in his life, that tuberculosis is by no means highly contagious, since practically no one has ever contracted tuberculosis in any of the well-conducted tuberculosis sanatoria, where proper precautions are always observed regarding the care of the sputum and the excretions of the patients.

There is, therefore, no reason why tuberculous patients should be treated like the lepers of whom we read in Scripture. These unfortunates were probably not a menace to their neighbors, since leprosy is probably not contagious, and they deserved far more considerate treatment than they received. The fear of being shunned by one's neighbors and of being isolated from one's family and friends keeps many sickly persons from submitting to an examination to learn whether or not they may be tuberculous. So people buy the nostrums they see so flauntingly advertised as "sure cures" for consumption, and hope against hope that they will throw off their colds "when the warm weather comes," and when they are finally brought under treatment the golden opportunity is gone to check the disease before it has made such substantial progress that it can be detected by the physical signs in the lungs.

We require all immigrants to be vaccinated before admission to this country. We send back across the ocean cases of trachoma, feeblemindedness, or marked bodily sickness, yet we allow many cases

of incipient phthisis, which cannot be detected with certainty unless all immigrants are properly tested with tuberculin, to settle among us. A matter of such importance should receive instant attention from those in authority.

Probably the establishment of properly equipped tuberculin dispensaries similar to those established abroad, especially in England, and, I presume, in Germany, will be the first practical step that we can take toward making sure that large numbers of people shall be tested for tuberculosis. Whether legal enactments will be necessary before people generally will submit themselves and their children to the tubercuin test it is too early to state.

Efforts have already been made to introduce routine tuberculin tests for tuberculosis into the schools, and this should be done without delay. The economic saving to the individual as well as to the State, if tuberculosis can be arrested in its earliest stage, is simply incalculable. The tuberculin dispensaries abroad report that they cure one hundred per cent. of the incipient cases they treat. Sutherland, an English writer, declares that eighty per cent. of all cases of tuberculosis can be treated without interfering with their occupations. In 1913 there were forty tuberculin dispensaries in England. Probably there are more now, and probably soon there will be a large number in America where rich and poor may go, if they choose, and learn all about their condition, so far as their liability to die of the great white plague is concerned; where young doctors may be taught the intricate and painstaking methods that the expert clinician must employ to immunize his patient against tuberculosis. In a properly equipped tuberculin dispensary, cultures can be made and *x*-ray pictures taken, and every appliance to aid the diagnosis and complete the cure of tuberculosis shall be in constant use and manipulated by the skillful hands of experts. These dispensaries shall be centers of teaching as well as of treatment. They must employ a certain number of competent nurses and health inspectors to do follow-up work to instruct those under treatment that they must observe the rules of hygiene, must avoid bad air and bad company, alcohol, injurious food, and so forth, if they wish to get the full benefit of the treatment and to more surely escape from their deadly infection.

While such work will be expensive, it will, in the end, prove to be the greatest measure of economy which any town, city, or country can practise. It would take a skilled statistician and economist to figure out the probable gain in material wealth alone, not to mention the actual saving of human life and the prevention of untold suffering, misery, and destitution. And, inasmuch as by a well-known law of sanitation, if one disease is expelled from a community the death rate from other diseases will be materially lessened, our general death and morbidity rate will be greatly diminished by a general use of tuberculin.

Doctor Bonime of New York has developed a method of administering tuberculin which it is firmly believed surpasses in accuracy and safety any other yet brought forward. It has the great advantage of fully enlisting the patient's interest and attention, and the results have surpassed anything before seen in America. If the patient shall come under treatment sufficiently early, and will follow instructions with reasonable fidelity, a cure can safely be promised him without interference with his occupation or ordinary mode of life.

If some of our noble-minded philanthropists would institute a string of tuberculin dispensaries in the United States like the well-known Rockefeller hook-worm dispensaries of the South, only somewhat more elaborate (since they must be more permanent, and fitted to handle a more complicated disease), the economic and sanitary advantage would be incalculable. They would need to be under some central control, and should employ only truly scientific and competent men, who should, like the employees of any corporation, be retained only so long as their work was satisfactory.

To assume that some such plan will be put into operation in a comparatively short time does not seem in the least unreasonable. To the writer's mind, it is impossible to conceive of any means by which money could be so economically and profitably invested.

42 Church Street.

OPERATIONS ON THE UTERUS AND THE VAGINA, WITHOUT AN ANESTHETIC.

By HENRY ALBERT WADE, M.D., F.A.C.S.,
BROOKLYN, N. Y.
VISITING SURGEON TO THE BETHANY DEACONESS HOSPITAL; VISITING GYNECOLOGIST TO THE WILLIAMSBURGH HOSPITAL.

THERE are certain areas in the genital tract in women poorly supplied with sensory nerves. The extent and location of these areas vary somewhat in different individuals, and in some women such areas are nonexistent. We have taken advantage of this relative anesthesia in certain portions of the genital tract, and are able in many cases to do reparative and corrective work on the uterus and the vagina without an anesthetic. After the operation has been completed the patient is able to return to her home without assistance, and only infrequently is she confined to her bed subsequently. These areas of relative anesthesia are: the mucous membrane lining the fundal and the cervical portions of the uterus, that covering the cervical portion of the uterus, and that lining the anterior and posterior walls of the vagina. The lateral walls of the vagina are much more sensitive. The areas of relative anesthesia in the anterior and the posterior walls of the vagina extend from about one-quarter of an inch from the junction of the cervix to the vagina above to one-eighth of an inch from the mucocutaneous junction at the outlet of the vagina. The degree of relative anesthesia of the interior of the fundal and the cervical portions of the uterus may be determined by the introduction within the cavity of the uterus of a uterine sound. The degree and the extent of anesthesia of the anterior and the posterior walls of the vagina may be determined by grasping the mucous membrane at different points with a mouse-toothed forceps. The age of the patient has a direct bearing upon the relative degree of anesthesia, the older the patient the less sensitive the lining of the genital tract. The surgeon should ascertain by the application of these tests that the field of operation is not sensitive before operating without an anesthetic.

The following conditions may frequently be relieved by operation without the aid of a general or a local anesthetic: Endometritis of the fundal or the cervical portion; lacerations of the cervical portion of the uterus, requiring either a repair or an amputation of the cervix; procidentia of the uterus due either to an hypertrophy of the cervix or to an increase in the caliber of the vagina; acute

flexions of the body of the uterus upon its cervix; cystocele; rectocele.

The patient is never informed as to the exact time the operation is to take place, or that the work is to be done without an anesthetic. After having determined that the field of operation is not sensitive, the patient is directed to call at the office at some appointed time, and after having loosened her clothes about her waist, she is placed upon the table in the dorsal position. The external genitals are then washed with soap and warm water, and the hair shaven over the mons veneris and the labia majora. She is then given a douche of physiological salt solution or of some mild antiseptic solution. The patient is then dismissed. At the time of her next visit the procedure varies, depending upon what portion of the genital tract requires operation, but in all cases no actual cutting or suturing is attempted until after the patient has made several visits to the office, and has become accustomed to being placed upon the table in the dorsal position, and has become accustomed to the manipulation of instruments about the lower genital tract.

In cases giving symptoms that we ascribe to an endometritis, the caliber of the cervical canal is enlarged by incising its walls with a knife, and the interior of the uterus is thoroughly painted with a 50 per cent. solution of tincture of iodine in alcohol. The application of the iodine to the endometrium is repeated from three to four times upon alternate days. The patient generally has some uterine cramps lasting from one to two hours after each application. In two cases of endometritis, at the request of the family physician, the uterus was curetted, using a sharp curette, with but little pain at the time of the curettement and with no untoward symptoms subsequently. We have treated eleven women by this method—nine with repeated applications of tincture of iodine to the endometrium, and two with curettement, followed by an application of tincture of iodine to the endometrium. The results have been fairly satisfactory, no better and no worse than the results obtained when the work was done with the patient under a general anesthetic.

The repair or the amputation of the cervix without an anesthetic is not difficult provided the uterus is movable and the vaginal canal is not contracted so that the cervix may be brought down to the entroitus. The late Dr. Alexander Skene in his work on "Gynecology," edition of 1890, refers to two cases of the repair of lacerations of the cervix, the operations having been performed in his office, with no subsequent ill results. Dr. H. J. Boldt has described a method of repairing the recently torn cervix in a paper entitled "Intermediate Trachelorrhaphy; Its Use as a Prophylactic Against the Pernicious Effects Sometimes Caused by Lacerations of the Cervix" (*Journal of the A. M. A.*, October 30, 1915). We have repaired 16 old lacerations of the cervix and amputated one cervix that was stellately torn. We have repaired 6 freshly torn cervices and amputated one cervix that had been previously torn at a former labor and had received further damage at the time of the patient's last confinement, seven weeks before the operation; there being but little of the cervical tissues remaining, the cervix was amputated without discomfort to the patient and with a good result. Of 16 repairs of old lacerations of the cervix, 12 resulted satisfactorily after the first attempt at repair. Of the 5 that were reoperated upon, 4 were satisfactory and one case resulted poorly. Of the 6 freshly torn cervices, the repair of 4 was satisfactory, one fair, and one poor; the latter, upon reoperation, gave a good result. In 2 cases we had postoperative bleeding, in one case a ligature slipped while the patient was still in the office, and in another case, five days after the operation, there was a brisk bleeding from the point of repair, probably from premature absorption of the catgut used. In both of these cases, much to our surprise, the repair turned out fairly well. These 2 cases emphasized to us the necessity of extreme carefulness in obtaining perfect hemostasis in operations upon the pelvic organs in women, where the patients are not subsequently confined to their beds.

The anterior vaginal wall has been repaired without an anesthetic in 4 cases. In one case the repair was satisfactory. Two women consented to be reoperated upon, and after the second operation the result was satisfactory.

The posterior vaginal wall was repaired in 6 cases. The result was satisfactory in 5 cases. The one failure was reoperated upon twice, and after the third operation the result was fair.

Stem pessaries were introduced into the cavity of the uterus in 6 cases of infantile uterus with acute flexions of the body of the uterus upon its cervix. The caliber of the cervical canal was enlarged, and the angle of flexion was obliterated by incision with a scalpel, and without discomfort to the patient. The introduction of the stem was then quite simple and accomplished without pain.

The cases reported in this paper number but 51, operated upon during the past 14 months. Our experience, therefore, is quite limited, but we have been impressed with the following facts:

The large number of women who will submit to these operations upon the lower genital tract without an anesthetic, and the willingness with which they consent to a second operation, after a few weeks' interval, in those cases where the result of the first operation has not been satisfactory. For this reason the end results in these operations done without an anesthetic compare favorably with the operations performed with the aid of anesthesia, when, if the result of the operation is not satisfactory, it is very difficult to obtain the consent of the patient to be reoperated upon.

Economically, this method of operating without an anesthetic has a decided value. Women with torn cervices frequently have not the means to leave their families and remain within the confines of a hospital for some days, and so allow the condition to persist until they have become chronic invalids, or until cells of a malignant character have become engrafted upon the seat of the old tear in the cervix, and in either case these women are not able to do their duty to their families and to society.

The operator should have had an extended experience in gynecological surgery with the patient under an anesthetic before attempting to operate without the aid of anesthesia.

From a review of our cases and the results obtained, we feel encouraged to continue in suitable cases these operations without an anesthetic upon the genital tract of women.

195 Greene Avenue.

The "Four Masters" in French Psychiatry.—According to Dupré the most illustrious psychiatrists in France form a continuous succession, including the relationship of master and pupil. These men are Pinel, Esquirol, Baillarger, and Magnan (just deceased).

THE BACTERIAL ETIOLOGY OF POISON-OAK DERMATITIS (RHUS POISONING).

By LOWELL C. FROST, M.D.,

LOS ANGELES, CAL.

THERE are few diseases at once more painfully annoying to the patient and more "unsatisfactory" to the physician than the dermatitis caused by contact with or proximity to the poisonous plants of the Rhus family. Like "rheumatism" and "eczema," this is an ailment for which there is a host of remedies claimed to be specific. This means unquestionably that in all these diseases our knowledge of the etiology has been inadequate as a basis for our therapeutics. It is the purpose of this paper to suggest a new line of approach to the problem in hand. It will be of advantage before presenting a new theory to review very briefly the essential points of the one which at present is vaguely, but generally, held.

It is remarkable and unfortunate that an affliction so widely spread throughout the country, and so exploited by the manufacturers of worthless "cures," should be so slighted in our standard textbooks. McCrea's five-volume edition of Osler's "System of Medicine" does not mention the subject in the text or the index, and some other supposedly authoritative works dismiss it with a few words of inherited tradition. Sollmann, in his "Pharmacology," makes an attempt to treat it scientifically. His view of the etiology may be taken as representing at its best the general opinion. According to this, all species of Rhus secrete in the lacteals of the leaves a fixed oil of extreme toxicity, and this is conveyed to the fine hairs on the leaf surface (Schwalbe, 1902). This fixed oil was isolated by Pfaff as toxicodendrol. This, after contact with the skin, remains latent from one to nine days, usually four or five days (Sollmann), and then sets up by purely chemical irritation a dermatitis which goes through all the characteristic stages to vesiculation and pustulation.

I wish to cite several cases of dermatitis caused by *Rhus toxicodendron*, poison-oak, and to report on the results of laboratory experiments with certain bacteria found on the leaves of this plant. On these cases and experiments I have based my reasons for believing that this dermatitis is *not* primarily the result of cutaneous irritation by a chemical poison; and that it *is* primarily a systemic infectious disease of the exanthematous type, caused by invasion by a definite bacterial organism. That the oily, active principle of the plant is irritating to the skin I do not doubt, but I believe that its toxic power is greatly exaggerated, and that the dermatitis should be ascribed almost wholly to other agents. These cases, selected from a large number which I have observed and collected during the past two years, are chosen as illustrating most clearly the points which I wish to emphasize. They are, however, strictly typical cases, selected as such, and not primarily for the purpose of bolstering up any hypothesis. My experience has been limited to the Western variety of the Rhus family, *Rhus diversiloba*, commnoly called poison-oak. From all I can learn of the Eastern varieties, *Rhus toxicodendron*, poison-ivy, and *Rhus venenata*, poison sumach, their effects have an etiology closely related to that of the variety here considered.

CASE I.—S. B. N., a healthy young American in the plumber's trade, had not been out of the city for three months, when he was called to San Francisco on business. He took a day-train, and had reached the summit of one of the mountain passes when he found that owing to a fire in the tunnel, the passengers were compelled to walk around the mountain, about a quarter of a mile, and re-entrain on the other side. The newly-made path was broad and well beaten and contained no shrubs nor roots. He noticed, however, that there was a luxuriant growth of poison-oak along almost the whole length of the path, the nearest of it being about fifteen feet from him, as he walked along. He did not come into contact with it, nor did anyone else in the party, with whom he might afterward have had contact. The wind was strong, and blew from the direction of the poison-oak toward him. He was perspiring freely at the time. After taking the train, which he did immediately on reaching it, he proceeded to San Francisco and remained in that city for two weeks without going into the country. There was thus no possibility of any other exposure to the infection than that afforded by the proximity described above, and contact, direct or indirect, is absolutely excluded. He had dismissed the incident from his mind when five days later a few typical vesicles appeared on the skin of the thigh just above the popliteal space. These were accompanied by itching and burning, with some local redness and swelling. Having suffered from one attack of poison-oak as a child, Mr. N. recognized these symptoms and called a physician; he also realized the futility and danger of scratching, and forebore carefully. Despite this and the conscientious use of grindelia and sugar of lead lotions, the characteristic exanthem rapidly spread, and in twenty-four hours had covered the posterior aspect of the thigh, the deltoid area of both arms, and the right side of the neck and face—which, it may be remarked, was the side farthest from the poison-oak and not struck by the wind at the time of exposure. The disease followed the usual course, the lotions having no influence except for a slight subjective cooling effect.

CASE II.—R. E. S., a Mexican-American ranch laborer, aged 62. S. lived in the Ojai Valley, Southern California, where there is an abundant growth of poison-oak, and owing to the fact that he seemed to possess complete immunity to its poison, he had for years often been hired to "grub out" the plant from the neighborhood of homes whose owners were susceptible. This work he always did with bare hands. On several occasions he ate the leaves of the plant to win wagers, but did not make a regular practice of this. He had never had any symptom of poisoning from this source, and had always been of rugged health. In the spring of 1915 he suffered a severe attack of pneumonia which left him much broken in health, and with a chronic bronchitis—possibly tuberculous. When he had recovered sufficiently to be again active, in June, he was hired to grub out some poison-oak bushes for a neighbor. As usual, he did this bare-handed. On the third day after this he developed an area of the characteristic exanthem on the neck, and in the course of two days it appeared on the backs of the hands, arms, and between the shoulder blades. The attack was only of moderate severity, the self-administered treatment consisting of local applications of carron oil, which seemed to be very effective in controlling the itching and burning.

CASE III.—O. A. H., a healthy young American twenty-eight years old, became a member of the U. S. Forestry Service in 1914. He had never suffered from poison-oak nor from poison ivy. Having only recently come to California from the East he was quite unfamiliar with the Western variety of the Rhus—poison-oak. While on his first trip of inspection in July, 1914, he pulled up and carried in his hand for several minutes a spray of the handsome crimson and green foliage. His more experienced companion on seeing it acquainted him with its true nature, and as soon as possible—about an hour later—had him wash and scrub with a strongly alkaline laundry soap, in accordance with the official recommendation for such cases as given by the Bureau of Forestry. The parts so treated remained free from any signs of poisoning, but three days later the typical exanthem appeared on the outer aspect of the calves of both legs, with the usual symptoms. He had been extremely careful not to touch any portion of his body with his hands after contact with the plant, and had thoroughly disinfected his boots and puttees with the strong soap solution; he had changed his clothes as soon as possible after his exposure, and had taken every precaution against any indirect contagion. In the matter of treatment he used only the soap solution, going

over the entire body with it twice daily, being careful to apply it to the affected area last, and to use a fresh cloth each time. The exanthem did not appear on any other area. The treatment seemed to relieve the discomfort very effectively, but did not shorten the course of the disease as manifested by the local signs.

Cases IV and V.—Albert S. and his mother, Mrs. J. H. S., aged respectively twelve and thirty-four years, both of good physique and active habit, were walking through the woods one day in September, 1914, when the boy ran to the roadside and picked a branch of pretty leaves. Mrs. S., knowing the plant to be poison-oak, snatched it from him with her own bare hands. When told what it is was, the boy impetuously ran back to the bush, picked several of the leaves, chewed, and swallowed them, explaining that his "scout-master" had told him that "this was the way the Indians used to cure themselves when they had touched poison-oak." On their return home a physician was called, who advised a cathartic and the washing of the boy's hands with baking soda. Mrs. S. had forgotten or did not mention her own exposure. On the second day Mrs. S. developed the typical exanthem which covered her face and both hands. It ran the usual course. On the eighth day the boy, who had been kept strictly at home meanwhile, showed a patch of the same eruption on his left upper arm, and the next morning another patch appeared on the right hand. There was some itching and burning, with the usual redness and swelling, but these areas did not increase in size, and subsided in less than four days, treated only with the baking soda lotion. His lips and mouth at no time showed any irritation, and he had no internal symptoms.

Case VI.—Mary H., American, aged 13. This young girl displayed a hypersensitivity to Rhus toxicodendron which resulted in what was almost a chronic infection. Her earliest attack was in 1908 at the age of six years, following the free handling of the plant; details of this attack are not available. It was said to have been very severe, however, and to have covered almost all of her body. After her recovery from this it was found that whenever she became overheated an eruption of the same type appeared on isolated and different areas, accompanied by the same signs locally and the same symptoms. Since that time she has had to date (1916) over twenty attacks, most often following an exposure from mere proximity to the plant by wind-blown infection, three times from an accidental contact, and five or six times when there was no known cause. The diagnosis has been made by competent medical authority in each case. The attacks have been decreasing in severity for the past three years, but scars on her neck and forehead which resemble those of a severe chicken-pox exanthem are said to have been made by former eruptions of the poison-oak. Although less severe, the attacks now last longer. Her parents tell me that the eruption appears from two to six days after exposure, in those instances in which there was definite knowledge of this. They have found that a saturated solution of washing soda (sodium carbonate) does more to relieve the distress than any other remedy, although they have tried all the standard "cures." Nothing seems to shorten or abort the attack, according to their report.

Case VII.—A. B., a Mexican youth of 17 years, of somewhat deficient mentality, while walking in the country found a shrub of poison-oak, picked some of it, chewed the leaves, and brought home a bouquet of the remainder. No signs until the seventh day, when he had a slight chill. The temperature was unrecorded. The next day his face became greatly swollen, with characteristic vesicles and general symptoms. His hands, arms, and genitals were also in the same condition. During the first week he suffered several attacks of nausea and vomiting, accompanied by indefinite, but persistent gastric pain. Recovery was uneventful, and was complete in eighteen days, apparently unhastened by the liberal use of many and various advertised "sure cures." No kidney irritation was observed at any time.

The following are the points to note in the review of these cases:

1. The incubation period. The average time in the cases cited was four and a half days. Minimum, one day; maximum, eight days. Sollmann* says "The active principle is the same for all species. It has a considerable latent period, from one to nine days, usually four or five days. *This does not seem to be influenced by the dose.*" (Italics mine.) I submit that it is hard to conceive of a chemical dermic irritant whose effects remain absolutely latent for four, five, or nine days; and it is almost impossible to conceive of such an irritant whose "latent period" is "uninfluenced by the dose." The bacterial hypothesis which I am proposing in this paper is confirmed by these same observations.

2. Complete natural immunity is shown by certain individuals. Cf. Case II. Sollmann says (*op. cit.*): *"Only certain individuals seem to be susceptible,* while others may handle or masticate all portions of the plant with absolute impunity." Fox states:* "While some may handle this vine with impunity, others are not only poisoned by its slightest touch, but even by its proximity." Can we conceive of a chemical irritant which respects individual immunities? Sollmann continues: "The reason for this is very obscure, but it may be remembered that certain animals are immune to cantharides." In this connection it is sufficient to note that the immunity referred to is relative, not absolute, and that only certain *animal* species are even relatively immune to cantharides. No human being has any immunity to any chemical irritant of such a high grade of toxicity. On the other hand, the bacterial hypothesis has in its confirmation the analogies of many other bacterial infections.

3. This immunity may be lost through a lowering of the physical resistance, or a hypersensitivity may be established. Cf. Cases II and VI. The reasoning in the last paragraph applies here with equal force.

4. Exposure may be strictly limited to proximity to the plant, as in Case I. In this regard, Sollmann says: "In susceptible individuals, an extremely small amount of the poisonous principle (1/1000 mg.) is sufficient to cause a violent dermatitis. In this way the poisoning may be spread by contagion, *i.e.* sufficient may be passed from the clothing or hands of one person to another to cause poisoning. *This is, perhaps, the only instance of contagion by a chemic poison.*" (Italics mine.) Again: "The toxic principle . . . is . . . a fixed oil (*toxicodendrol.*) The authenticated cases of poisoning at a distance, which would seem to speak for its volatility, can probably be explained by the oil being carried by dust, pollen, etc." I will leave the reader to balance the chemic-poison hypothesis with the bacterial, keeping in mind the details of Case I. Either the fixed oil—carried by pollen or dust—or bacteria must necessarily have been the windblown agent. I have examined the region near to the locality where the exposure took place, and find that there were no pollen-bearing plants in flower at that time. And just how would flying dust particles pick up a charge of the poisonous fixed oil?

5. The first appearance of the exanthem is often on an area untouched directly by the plant, and protected from subsequent indirect contagion or windblown virus. Cf. Case III. This would in itself seem to necessitate the hypothesis of a general infection with local manifestations, and this hypothesis is, I believe, supported by every other recorded observation in such cases.

The following notes on *Rhus* poisoning, by Hirschler in the Reference Handbook of the Medical Sciences, 3d Ed., Vol. VI, p. 510, are of interest as noting the occurrence of signs and symptoms indi-

*Sollmann: Pharmacology. Ed. of 1906, page 709 *et seq.*

*Fox, George Henry: "Diseases of the Skin," Article "Dermatitis."

cative of a general infection, and as recognizing the existence of cases of infection without contact with the plant, and of the existence of individual immunities and susceptibilities: "There are individuals, too, who from childhood have never been subject to plant poisoning, but with change of climate or methods of living are suddenly rendered susceptible. Some general symptoms may arise during the progress of the eruption. Nervous symptoms from the suffering are common, and rather rarely there is a chill followed by a fever of 101° to 102° F., with rapid pulse and prostration. Many persons who have had at one time or another an attack of severity have found that in passing through the woods, or anywhere in proximity to the plant, they may have a recurrence of the attack, even though the plant has not been touched. The writer has personally verified this, but finds that as the years pass, and there has been no new contact with the ivy, the peculiar susceptibility to the air-laden poison [*sic*] becomes almost nil."

Duncan, in an article in the *New York Medical Journal*, Nov. 14, 1916, ingeniously erects from the combined principles of anaphylaxis and homeopathy a new theory of treatment which he calls *autotherapy*, and illustrates his thesis by the autotherapeutic treatment of ivy poisoning. This consists of the traditional eating of the leaves when in dangerous contact with the plant. He states that he has long employed this method of treatment, the implication being that it has been succcessful. He also states that "in Fairmount Park, Philadelphia, a few years ago, and in Bronx Park, it was the custom to instruct park hands, when hiring them, to chew a few leaves of the poison-ivy plant when clearing away the vines, as a preventive." From the viewpoint of bacterial etiology, this treatment would be the equivalent of the administering of tuberculin per os, since the bacteria would be destroyed in the gastric juice and their endotoxins liberated and absorbed, to stimulate the formation of specific antibodies in the tissues.

Owing to the lack of special equipment, the results of my approach toward the problem from the laboratory side are incomplete. They are, however, very suggestive.

Bacterial cultures made in August, 1915, from the fresh green leaves and from the older red ones of the *Rhus toxieodendron* show several types of cocci and bacilli. Only one type of bacteria was apparently constant on all the leaves examined. This type was found to be most abundant on the under side of the leaves collected from several sources, and was a short, thick bacillus, rather variable in its dimensions, but usually found to be about two microns in width and three to four microns long. It was of strictly aerobic growth, and produced spores, one highly refractive spore appearing in each bacillus in old colonies which had been subjected to drying in the air for several days. The same spore-bearing form was predominant on the reddish overmature leaves. The growth was not good on agar, gelatin, or bouillon, but was abundant on potato at room temperature. These bacilli stained well with methylene blue and with gentian violet, the spore-bearing forms showing up well with Neisser's double stain or with very weak carbol-fuchsin.

The culturing of these bacilli lessened whatever virulence they possessed originally, for inoculation by inunction of the pure culture into the skin produced, after 48 hours, only a slight redness, without itching or burning, and followed by no further symptoms.

With the facilities at my command I was unable to determine whether or not the bacilli form any soluble toxin, or whether an antitoxin could be produced by suitable means. Nor could I carry out the experiments obviously needed to determine the possibility of producing an active immunity through the use of a bacterin made from these organisms. No animal experiments were undertaken.

These are lines along which I believe brilliant and very practical results may be attained by properly qualified and equipped laboratory technicians.

Medicolegal Notes.

Expert Opinion as to Cause of Injury—Physical Examination of Injured Porson.—In an action for injury to a girl of about 17, while a passenger on the defendant's street car, in a head-on collision, it appeared that after the accident her menstruation became irregular and obstructed. Complaint was made by the defendant that physicians were allowed to testify that in their opinion the plaintiff's injuries, as testified to, could, and probably did, produce the obstructed menstruation, and that this was an invasion of the jury's province. The court held that, while it was true that the ultimate facts respecting the extent of the alleged injuries and damages, and what caused them, were for the jury, it was also true that, in case the injuries which are suffered by an individual, as in this case, where the extent thereof cannot be observed in the ordinary way, and it is shown that certain invisible organs of the body are affected, a physician who testifies as an expert may give his opinion concerning the effect that a certain injury on the body may produce upon such organs. Certainly the jurors, merely laymen, and wholly inexperienced in such matters, could only guess at what effect certain injuries to the body might have on certain sexual organs of an injured female. While it may be true that a physician may not absolutely know, or be able to say with positiveness (since it is largely a matter of diagnosis), just what may have caused the ailment, yet, as an expert, he may give his opinion. It is for the jury to say what, if any, effect they will give to such evidence.

The defendant's counsel at the trial asked the court to make an order that the plaintiff be required to submit to a physical examination to be made by certain physicians selected by the defendant, and in the presence of the plaintiff's physician and of her father. The court declined to make the order on the ground that it was powerless to do so, in view of its former ruling in Larsen v. Salt Lake City, 34 (Utah), 318. This is a point on which the decisions are in conflict.—Sharp v. Ogden Rapid Transit Co., Utah Supreme Court, 160 Pac. 438.

Medical Evidence as to Effect of Eating Tainted Meat.—Action was brought against a retailer of meat for damages for sickness alleged to have been caused by eating unwholesome dried beef sold by the defendant. It was alleged that the plaintiff ate of the meat soon after purchasing it, and that it caused him to become ill, to be thrown into fits and spasms; that his digestive system had become so impaired as to render his life a burden to himself and his family; that he had lost control of his excretory organs, and that his health had become permanently impaired. It was urged by the defendant that the trial court erred in admitting the testimony of two physicians, who expressed the opinion that the plaintiff's sickness was caused by eating the meat, because their opinion was based partly upon the history of the case as detailed to them by the plaintiff. It was asserted that this should have been excluded as hearsay. But neither of the physicians repeated what the plaintiff had said. It was obvious that no intelligent examination could have been made, nor any intelligent opinion expressed, without taking into consideration both the subjective and the objective symptoms. The evidence was held not objectionable as being hearsay.—Fleisher v. Carstens Packing Co., Washington Supreme Court, 160 Pac. 14.

THE ETIOLOGY OF SCARLET FEVER.

NOTHING definite is known of the cause of scarlet fever, though a vast amount of work has been done on that disease and much of the bacteriology of its complications is reasonably settled. The part played by the streptococcus, though of the greatest importance, especially so far as the complications are concerned, has generally been considered to be that of a secondary invader. Mallory and Medlar (*Jour. of Med. Research,* 1916, xxxv., 209) searched for a possible organism in sections made from the pharynx of patients dying early in severe attacks, making use of stored material from autopsies performed some years ago. They describe the almost constant finding of a slender Gram-positive bacillus in the mucous membrane at the edges of the ulcers or erosions, which they believe to be the primary lesion of the disease. These organisms were found almost constantly early in the disease and were absent in sections made from autopsies where scarlet fever was not present. They were able to study no very acute cases because of the mildness of the disease in Boston during the past year, but made cultures from those cases which did come under their observation. Cultures of an organism resembling, in morphology and staining properties, the one seen in tissue sections were obtained in five instances from cases early in the disease.

The writers have named this organism *B. scarlatinæ* and think that it is reasonable to infer that it is the cause of scarlet fever. In uncomplicated fulminating cases this causative agent is present in large numbers in the lesions in the respiratory tract, but dies out quickly in the milder cases. Their arguments in favor of the idea that this organism is the cause of scarlet fever are that it was found abundantly and extensively distributed in five cases. Moreover, it was found only in children who had had scarlet fever. Control examinations of tissues from over five hundred cases, mostly from the contagious department, failed to show it. It has not been encountered as a pathogenic secondary invader in other fatal diseases.

The organism studied by Mallory and Medlar seems to be a diphtheroid, or a member of that group, and in this fact lies much of the objection that will be made to the acceptance of it as *B. scarlatinæ*. The diphtheroid group have been blamed at one time or another as the causative agent of a number of unrelated conditions, such as Hodgkin's disease and typhus fever, and often with much more evidence than is presented by these authors. But the diphtheroids are a ubiquitous family and seem always to intrude where they may cause the most difficulty to us, with our gross methods of differentiation. These authors, of course, do not pretend that they have discovered the cause of scarlet fever, and present this theory only as what seems to be a logical inference from the work which they report. Nevertheless, it would seem wise to remember that in the diphtheroid bacilli we have a group of organisms which have caused much confusion in the past and are evidently to continue their annoying habit in the future.

AMBIDEXTERITY.

THE European War has brought the subject of ambidexterity into prominence. A very large number of men have been and are being maimed by the loss of the right hand or arm. The movement for rendering men incapacitated as the results of wounds able to follow their former or other trades and callings was initiated in France, and great success has attended such training. In Great Britain also disabled soldiers are being trained with care and intelligence to follow trades or work most suitable to them. A loss of the right arm prevents a man in nearly every instance from pursuing his previous employment; indeed, for a time, at least, until he can be trained to use the left hand or is fitted with some prosthetic apparatus from doing any manual work. From almost time immemorial man has been a right-handed animal. The first man was, probably, "bidexter" or "ambidexter," as it can scarcely be imagined that he emerged into life with an inherited instinctive right-handedness. There have always been, during all ages of which any history or tradition has been handed down, ambidextrous individuals and sometimes a race has possessed, possibly by training, two handed dexterity; thus the inhabitants of the Balearic Isles who gained great fame in the far off times in which they lived by their ambidextrous manner of slinging. Also we find mention in the Old Testament of the 700 Benjamite slingers, who were able to demonstrate in the most practical way how useful it was in a battle, and especially in a battle in which man and not machinery counted most, to be able to hurl the missiles from the sling with one or the other arm equally well. There were doubtless more left handed or ambidextrous persons in the old times than now, Plato, Aristotle, and other of the ancient writers frequently referring to ambidexterity; although the Japanese of the present day are reputed to be, in a large measure, a left-handed people. But among Europeans and Americans an ambidextrous man or woman is a rara avis.

Without dwelling upon the apparently overwhelming advantages of two handedness, it may be interesting to notice one objection which is frequently urged against ambidexterity. This relates to the mental or physiological effects. Some medical men have voiced the fear that the extra labor thus imposed upon the brain would endanger the intel-

lectual and mental standard of the individual. The supporters of ambidexterity, however, contend that ambidextral instruction does not entail extra work on the brain, but rather distributes the work to be done over a double area of brain matter. Instead, therefore, of one side or hemisphere of the brain having all the work to do and the other lobe becoming atrophied through disuse, both sides are alternately or simultaneously and symmetrically engaged, exercised, and developed, and ultimately in adult life each half takes its own proper share of the daily task; thus each lobe is proportionately benefited by this division of labor. So far as many of the victims of the war are concerned, it would certainly seem that ambidexterity would have been a blessing. A man who can use both hands in his work is much less helpless when he is disabled than one who can use only his right hand. When a man has been bereft of his right arm and has to earn his living, the question is raised in the vocational homes whether to fit him with an artificial hand and teach him to use this or to train him in the use of his left hand. A great deal of success has been attained already in the training of disabled soldiers in the use of the left hand, and unless the objections brought against this can be sustained by more conclusive evidence than any that has yet been brought forward, it would seem to be decidedly preferable in the majority of cases to train the left hand than to make the cripple dependent upon an artificial hand.

As was said above, the movement for the training of soldiers crippled by loss of the right hand or arm were initiated in France. In the *Revue Scientifique* it is stated that Mlle. Josefa Joteyko of the Collège de France, who has studied thoroughly neuromuscular physiology, has planned a scientific method for the education of the left hand in cripples where the right hand has been maimed or lost. The theory is that since the body is bilaterally symmetrical, the left hand should be trained to carry out the movements of the right hand in an inverse direction, or what might be termed "mirror movements." It was found, however, that an amount of work performed by the left hand, that usually done by the right hand, produced a greater strain on the heart. Therefore, all cripples using the left hand for right-hand work should undergo a periodic examination of the heart, and the extensive use of the left hand should be limited to certain trades or professions, and the work should be changed when it is found that too great a strain is being thrown upon the heart.

It would undoubtedly have been greatly to the advantage of those who have lost their right arms if they had previously been ambidextrous, and there is no proof that either heart or brain suffers unduly from two-handedness; the Japanese, if it is true that they are largely ambidextrous, do not seem to have suffered thereby, for they are as hardy and as mentally alert a race as any on earth. The arguments in support of the training of the left hand are stronger than the objections which have been brought against such training, and the wounds of war appear to have supplied a powerful plea in favor of ambidexterity.

COMPTOCORMIA.

THIS term, which means literally flexed trunk, has been applied to a static deformity resulting from the accidents of modern warfare. The point of flexion is at the level of the first lumbar vertebra. The subject exactly resembles a normal man whose spine is in a state of physiological flexion. The profile shows nothing abnormal. There is a compensatory extension of the head in the interest of vision, and the abdominal muscles are contracted. The patient is not much inconvenienced, and walks with a cane. Upon examination, one is surprised to find perfect suppleness of the vertebral column, with normal mobility of the spine. The condition is evidently a purely functional one, which could readily be simulated.

The condition seems to have been first noted by Souques in patients in the Salpêtrière. Mme. Rosanoff-Saloff has studied sixteen cases, and an abstract of her work is found in the *Journal de Médecine et de chirurgie pratiques* for September 25. Ordinary methods of diagnosis failed to reveal any indication of organic disease. The deformity affected both wounded and unwounded soldiers, the latter being much more numerous. In fact, but two of them had been wounded, and in one case the injury was remote from the point of flexion. Of the unwounded men, the great majority had suffered from shell shock, and suffered violence at the dorsolumbar spine. As a rule, they remained unconscious for a considerable period. Bruises over the spine were mentioned by the victims, but on examination neither wound nor fracture was in evidence save in the exceptions mentioned. Lumbar pain had invariably been present at the outset, and in certain cases had persisted for months, slowly abating thereafter. The pain is described as severe and incessant, aggravated by the slightest movement. During this period the sufferers remain in bed, in the attitude least uncomfortable, until the lessening of the pain permits them to rise in the flexed position. All treatment is unavailing. Spinal puncture now shows that if any abnormalities had been present originally their consequences must have totally disappeared. The muscles, which were for a long time immobilized by suffering, may now show contractures, which, however, may be regarded in part as psychogenic. The treatment may be briefly summarized as "plaster jacket and suggestion." A general anesthetic is indicated in some of the cases in which the jacket is to be applied. Once the corset has relieved the patient, the latter must be handled with a certain strictness of discipline. He is not allowed to receive visits or write letters, and is made to suffer other privations until it is time to remove the corset. When this is done he must be told firmly that his recovery is complete. In this manner Souques succeeded in curing all of the patients.

CURING SCARS BY ELECTRICITY.

THERE are some who think that the present aeon will be known to posterity as the electrical age. At any rate that potent force is coming to play a larger and larger part in industry, in war, and a

not insignificant part in medicine. Textbooks on electrotherapeutics are gradually becoming bulkier, so that we may look forward to the day not so far distant when no physician will think of hanging out his shingle without a battery in his office. The European War has greatly increased our knowledge of the practical application of electricity, particularly in regard to the detection of the location of bullets and other foreign bodies in the tissues and the examination of parts of the body which have suffered some nerve injury to determine diagnosis and prognosis. Lately we have seen a new application of electricity in the treatment of painful or adherent scars.

In *La Presse Médicale* for August 3, Drs. Chiray and Bourguignon report their experience in treating scars which have become contracted or adherent by ionization with potassium iodide. These doctors have been neurologists to one of the French military divisions and so have had ample material with which to work. Their method was to apply to the scar a negative electrode, its covering soaked in a 1 per cent. solution of potassium iodide. The positive electrode was wet with distilled water and applied to the other side of the limb. Zinc or tin electrodes were used and were covered with asbestos. They were about two feet square, the current was generally 10 milliamperes, and each séance was one hour long. The stages of the treatment were as follows: The scar at first became paler, then thinner and not so indurated, while the skin itself felt more pliable. Finally, the scar became separated from the underlying tissues and could be easily moved over them. Treatments were given every day at the beginning, and the first improvement became evident usually a few weeks after starting them, rarely as early as the eighth or tenth day, but often not for five or six weeks. Chiray and Bourguignon believe that the treatment should be kept up for at least three or four months.

The above is a valuable addition to the medical lessons taught us by the war and will undoubtedly be noted by American surgeons. It is impossible in the event of war to treat all wounds *secundum artem*, and it is inevitable that in some cases scars should result which by their contraction cause discomfort and hinder motility. The ionization method seems to offer an effectual way of dealing with such unpleasant conditions.

Health of the Navy.

One of the most encouraging signs of the times is the awakening of the civilized world to the importance of personal health and sanitation. While every effort is now being made by means of lectures and practical instruction to enlighten the general public on matters of health and hygiene, the Government through the Army and Navy has lost no time in carrying out plans for the development of hygiene of the highest type. In his annual report for the fiscal year the Secretary of the Navy says that the chief object of concern to the Surgeon General and the Medical Corps of the Navy is the matter of health and sanitation and the clean living of the personnel essential to efficient service. Few people outside of the Navy realize how carefully guarded as to health conditions these young men are. When a comparison is drawn between the men who enter commercial or other walks of life and those in the Navy, the secretary expresses wonder that more young men do not choose the sea for a life occupation; it is probably, he thinks, due to a knowledge only of its apparent hardships, and an ignorance of its advantages for a healthy life. Mortality statistics show that eight out of every thousand men on land die from the ordinary risks of disease and accidents annually during what should be their healthiest years; while last year only 4.48 per 1,000 of the naval personnel were lost by death. This is in itself significant. Tuberculosis gave but 11 per cent. to the death roll, while during the same period in civilian life 30 per cent. of total deaths between fifteen and sixty years were due to this disease. This, however, is of course an unfair comparison, for the sailor is a picked man and no one with incipient tuberculosis would be accepted for the service. The report, indeed, states that during the past year of the 106,392 men who applied for enlistment in the navy, only 30.18 per cent. were accepted. The present rigidity of physical requirements not only insures a high standard of health among the men, but helps to lighten the pension load of the country in the coming years. The work in sanitation which was carried out in Panama and Porto Rico by the Government has also been begun for the people in Hayti and Santo Domingo. That the Government is fairly alive to the advantages of health among the men to whom its first line of defense is entrusted is shown by the increase in appropriations for the medical department from $682,000 last year to $1,187,728 for the current year.

The Brain and Life of Rubén Dario.

The brain of the Spanish poet, Dario, bequeathed to Dr. J. J. Martínez, has been found to weigh 1850 gms., which places it in the same rank with the brain of Dupuytren, Cuvier, and Abercrombie. The cortex and convolutions showed superior development. Dario was precocious, a boy poet, dominated by his emotions. He was, in fact, highly neuropathic and had night terrors in early childhood. He frequently abused alcohol, which often caused delusions of grandeur. He slept poorly. His memory was prodigious. His character showed great weakness. He was always in love. He beheld visions not only at night but in the daytime, and at times seemed to have telepathic and clairvoyant powers. Dr. Galceran Granés in the *Gaceta Medica Catalana* for October 31 sums up Dario as follows: He was incomplete or "not all there," was unbalanced, a Bohemian. He could be summed up as intensive, imaginative, with a prodigious memory. His retention and constructive imagination are apparent in his poetry, but these do not constitute genius or originality, as apposed to formalism. While he always suggested genius, this was apparently dominated by the formalistic. Nevertheless, he was chiefly independent of outside influences. Apparently the extremely contradictory attributes possessed by him are the most certain evidence of lack of balance. Nearly every statement made about him must at once be qualified. The main lesson is that an unbalanced person who is a genius may possess a brain equal in size and with convolutions apparently as well formed as that of a genius who is well poised.

Lumbar Puncture of the Fetus During Podalic Version.

It would hardly suggest itself *a priori* that the withdrawal of a few cubic centimeters of cerebrospinal fluid from the fetus would materially facilitate the moulding of the head; yet Professor Costa, director of the Royal School of Obstetrics at Novara, employs this resource systematically in his clinic (*Il Policlinico*, 1916, XXIII, Medical Section, p. 1212). In addition to his clinical work he has made experiments along these lines. He claims that not only is there a greater compressibility of the head, but a lessened compression of the nerve centers, especially of the respiratory and cardiac centers. After the trunk has been partly delivered, the spine of the child is flexed by an assistant and the needle inserted between the fourth and fifth lumbar vertebræ. Aspiration is contraindicated, for as the fetal head passes through the pelvis the fluid escapes spontaneously. The use of this resource tends to cause an increased dependence on podalic version whenever there is any difficulty whatever in the passage of the head through the inlet, or when there is incomplete dilatation of the cervix. From another viewpoint, in any podalic version, irrespective of indication, lumbar puncture will render less difficult the birth of the head.

News of the Week

American Congress on Internal Medicine.—The first scientific session of the American Congress on Internal Medicine, which was chartered only last year, will be held at the Hotel Astor, New York, on December 28 and 29, under the presidency of Dr. Reynold W. Wilcox, who will address the members on "The Domain of Internal Medicine and the Purport of the Congress." On the first day of the congress there will be a discussion on the ductless glands in cardiovascular diseases and dementia precox, and on the second a symposium on duodenal ulcer. Following the congress a convocation of the American College of Physicians will be held, at which time candidates for fellowship in the college will be elected. All communications and inquiries relative to these meetings should be addressed to the secretary general, Dr. Heinrich Stern, 250 West Seventy-third Street, New York.

Symposium on Cancer.—In connection with the convocation in New York the last part of this month of the American Association for the Advancement of Science, a symposium on cancer will be held at a meeting at the American Museum of Natural History, Columbus Avenue and Seventy-seventh Street, at 2.30 P. M., on Friday, December 29. The American Society for the Control of Cancer has been asked to co-operate in bringing to public attention this important meeting, the program for which has been arranged by Prof. E. O. Jordan and Prof. C.-E. A. Winslow. The speakers and the title of their addresses are as follows: Prof G. N. Calkins of Columbia University, "The Stimulating Effects of Protoplasmic Substances on Cell Division." Prof. Leo Loeb of Washington University, St. Louis, "Tissue Growth and Tumor Growth." Dr. Joseph C. Bloodgood of Johns Hopkins University, "Cancer in the Human Being." In addition, Dr. James Ewing will summarize the latest experience and conclusions regarding the use of radium in the treatment of cancer, and Mr. Curtis E. Lakeman, executive secretary of the American Society for the Control of Cancer, will tell of the past and present efforts to combat this disease through the education of the public. The meeting will be open to the general public as well as to the medical profession.

Navy Hospital Ship.—The projected navy hospital ship, construction of which has been authorized, will be the first vessel designed and built for this purpose by any nation, it is said. Every convenience of an up-to-date shore hospital has been provided, and provision will be made for 300 patients in peace times and 500 in war. The ship will carry special stabilizers to minimize rolling and pitching, and will be equipped with laboratories, a complete *x*-ray plant, and a full shore-going hospital outfit, including ambulances.

Leprosy in Newark.—A case of leprosy has been reported from the Newark City Hospital. The patient, a Syrian rug peddler of Springfield Mass., is being held in the isolation ward. He has been in this country two and a half years.

Ban on Heroin.—All physicians of the United States Public Health Service have recently been ordered not to dispense any heroin for any purpose hereafter, and to return to headquarters any quantities of the drug they may have on hand. This action has been taken in the hope of counteracting the increasing use of heroin throughout the country. It is pointed out that less dangerous agents possess as powerful medical qualities, and that the sooner physicians realize this the easier it will be to curb the constant increase in the number of habitual heroin users.

Nurses' Home Dedicated.—The Central Club for Nurses, New York, dedicated its new building at 132 East Forty-fifth Street, on December 10. The membership of the club already numbers more than 800, representing 250 nursing schools, and although the building has just been completed it is already overcrowded.

Centenarian Dead.—John M. Phipps of Shenandoah, Ia., died suddenly at his home on December 10, aged 105 years.

"Anesthesia Rag."—A dispatch from Chicago to the New York *Sun* introduces the "anesthesia rag," with the following explanation: "The operating room at Columbus Hospital was equipped with a phonograph by order of the surgeons when a patient failed to succumb to the anesthestic. A popular air was started. The patient was soothed into accepting the anesthetic and his appendix was fox trotted out without a misstep. The method will be used regularly."

Site for Tuberculosis Hospital.—The Nassau County (N. Y.) Board of Supervisors on December 13 voted to purchase a 100-acre farm at Bethpage, L. I., to be used as the site for a tuberculosis hospital for the county. At a referendum election some months ago the people of the county approved of the appropriation of $100,000 for the site and the hospital.

Civil Service Examination.—The United States Civil Service Commission will hold an examination on January 3, 1917, open to men only, for the purpose of filling vacancies in the position of deputy collector, inspector, and agent under the anti-narcotic act. There are at present about seventy-five vacancies in this position in the Internal Revenue Service, Treasury Department, at $1,600 a year, with actual traveling expenses and subsistence while away from post of duty on official business. Graduation in pharmacy or medicine from a recognized

institution, or the possession of a State license to practice pharmacy, is a prerequisite for consideration for this position. Further details may be obtained on application to the United States Civil Service Commission, Washington, D. C.

Personals.—Dr. F. E. Harrington of the United States Public Health Service has been assigned by Surgeon General Blue for a year's health work in Jefferson County, Alabama.

Dr. C. Frederic Jellinghaus announces the removal of his office to 572 Park Avenue, New York.

Dr. Millard Knowlton, chief of the Bureau of Education and Publicity of the New Jersey State Department of Health, has tendered his resignation, to take effect on January 15. Dr. Knowlton plans to continue his studies in public health in Harvard University and the Massachusetts Institute of Technology.

Dr. E. R. Hildreth, resident physician at the Presbyterian Mission Hospital, San Juan, Porto Rico, who has been in the United States on furlough, sailed from New York on December 15 to resume his work.

Dr. Henry A. Bernstein has been elected Obstetrician and Associate Gynecologist, to the Beth David Hospital, New York City.

General Gorgas Returns.—The International Health Board Commission of the Rockefeller Foundation, headed by Gen. W. C. Gorgas, U. S. A., which has been carrying on a study of yellow fever and other contagious diseases of the tropics, returned to New York on December 11. In addition to General Gorgas the party comprised Dr. Henry R. Carter of the U. S. Public Health Service, Dr. C. C. Lyster, Dr. Eugene R. Whitmore, and Dr. William R. Wrightson. Dr. Juan Guiteras, also a member of the commission, stopped off at Barbados to investigate yellow fever conditions there. The report of the commission will be made public shortly through the Rockefeller Foundation.

Enforced Health Insurance Opposed.—The directors of the Board and Trade Transportation of New York, anticipating the reintroduction in the Legislature of the bill for compulsory State health insurance, put themselves on record recently as opposed to such "arbitrary and unsound legislation." The bill is considered too arbitrary because the liability of various classes of workingmen to illness or disease varies, because much depends upon the workingman's habits, intelligence, and sobriety, and because the responsibility of employers varies so greatly.

Gifts to Charities.—By the will of Mrs. Mary Warden Harkness of New York, who died recently, bequests are made to a number of charitable and educational institutions. Among the gifts to medical institutions are the following: $10,000 to St. Bartholomew's Church, New York, for the purposes of its clinic; $100,000 to the Morristown Memorial Hospital, Morristown, N. J., for endowment; $100,000 to the Flagler Hospital, St. Augustine, Fla., for endowment; $100,000 to the Germantown Dispensary and Hospital, Germantown, Pa., for endowment; $50,000 to St. John's Guild, New York, as endowment for its fresh-air work; $100,000 to the Babies' Hospital, New York, for endowment; $100,000 to St. Mary's Hospital, New York, for endowment.

By the will of the late Joshua L. Bailey of Philadelphia bequests are made as follows: Pennsylvania Hospital $5,000; Bryn Mawr Hospital, Philadelphia Hospital for Women, Frederick Douglass Hospital, Lying-In Hospital, Friends' Hospital for the Insane, Oncologic Hospital, each $2,000.

To Treat Occupational Diseases.—The Medical Board of the Union Hospital, Borough of the Bronx, New York, at a recent meeting voted to establish a division of occupational diseases with Dr. Frederic W. Loughran as attending physician in charge. Patients treated in this division will, before their discharge, be instructed in methods of lessening or preventing the dangers that surround them while at work; and, should opportunity offer, employers will be advised as to the value of industrial hygiene.

Gift to Long Island College Hospital.—It has recently been announced that the late Dr. John A. McCorkle of Brooklyn, before his death, set aside, in trust for the Long Island College Hospital, bonds of the value of $50,000, thus forming one of the largest gifts ever made to a medical institution by a physician in active practice. As the bonds became payable to the college upon Dr. McCorkle's death, the gift did not become known at the time his will was read. A committee of citizens of Brooklyn has now undertaken to raise an equal amount as a memorial to Dr. McCorkle.

New West Side Hospital.—Plans are being prepared for the erection of a new hospital to be known as the St. Nicholas Hospital, on the upper West Side of New York, a part of the city where hospital provision has not kept pace with increase in population. A site running through the block between St. Nicholas and Edgecomb Avenues at 148th Street has been donated to the incorporators of the hospital, and a large portion of the building fund has already been subscribed, it is stated. The first building, which will be erected as a unit so that others of a similar type may be added, will be a five-story building with accommodations for sixty patients. The State Board of Charities now has the application for a charter for the hospital under consideration, and the plans for the buildings and general scope of the hospital will also be submitted to the Hospital Committee of the New York College of Surgeons. The chief of the medical division, it is announced, will be Dr. Harlow Brooks, and the surgical division will be under the charge of Drs. Seth M. Milliken and John T. Moorhead.

Medical Society Elections. — ANDROSCOGGIN COUNTY (ME.) MEDICAL ASSOCIATION: The annual meeting of this society was held in Lewiston on December 5, when the following officers were elected: *President*, Dr. S. E. Sawyer, Lewiston; *Vice-President*, Dr. E. B. Buker, Auburn; *Secretary-Treasurer*, Dr. L. F. Hall.

KENNEBEC COUNTY (ME.) MEDICAL SOCIETY: At the annual meeting held on December 7, in Augusta, the following officers were elected: *President*, Dr. O. C. S. Davies, Augusta; *Vice-President*, Dr. A. U. Desjardins, Waterville; *Secretary*, Dr. S. J. Beach, Augusta; *Treasurer*, Dr. Stephen E. Vosburgh, Augusta.

SOUTHWESTERN MINNESOTA MEDICAL ASSOCIATION: The annual meeting of this association was held in Mankato on December 4, officers being elected as follows: *President*, Dr. A. F. Schmitt, Mankato; *Vice-Presidents*, Dr. W. F. C. Heise, Winona, and Dr. A. Olson, Nicollet; *Secretary*, Dr. W. T. Adams, Elgin; *Treasurer*, Dr. G. F. Merritt, St Peter.

Obituary Notes.—Dr. SILAS A. BOAM of Topeka, Kan., a graduate of the University of Birmingham, England, in 1870, died at his home on November 15, from heart disease, aged 70 years.

Prof. Hugo Münsterberg, whose sudden death occurred in Boston on December 16, at the age of 53 years, was a graduate in medicine from the University of Heidelberg in 1887. Five years later he came to this country to take up the work of professor of psychology and director of the psychological laboratory at Harvard University, which he continued until his death. He did no work in medicine, although the field of psychotherapy attracted his interest, but as a psychologist he received the widest recognition.

Dr. John McGuffin of Hastings, Mich., a graduate of the Detroit College of Medicine and Surgery in 1900, died at his home on November 7, aged 42 years.

Dr. Riland Dillard Berry of Springfield, Ill., a graduate of the Medical College of Ohio, Cincinnati, in 1879, and a member of the American Medical Association, the Illinois State Medical Society, and the Sangamon County Medical Society, died in St. John's Hospital, Springfield, on November 3, from cerebral hemorrhage, aged 61 years.

Dr. Isaac H. Mayer of Willow Street, Pa., a graduate of the Jefferson Medical College of Philadelphia in 1859, died at his home on November 13, aged 73 years.

Dr. Verne Ernest Winston of Keystone, S. D., a graduate of the University of Illinois, College of Medicine, Chicago, in 1903, died in the Methodist Deaconess Hospital, Rapid City, S. D., on November 12, following an operation for appendicitis, aged 37 years.

Dr. Robert E. Cunningham of Castile, La., a graduate of the Medical Department of the University of the South, Sewanee, Tenn., in 1902, died suddenly at his home on November 11, aged 44 years.

Dr. Joshua H. Gheesling of Greensboro, Ga., a graduate of the Medical Department of the University of Georgia, Augusta, in 1879, and a member of the American Medical Association, the Medical Association of Georgia, and the Greene County Medical Society, died in the Grady Hospital, Atlanta, on November 20, following an operation, aged 60 years.

Dr. John Frank Kane of Minooka, Pa., a graduate of Georgetown University, School of Medicine, Washington, D. C., in 1911, and a member of the Medical Society of the State of Pennsylvania, and the Lackawanna County Medical Society, died in the Mary Kellar Memorial Hospital, South Scranton, Pa., on November 20, following an operation, aged 32 years.

Dr. James M. Evans of Clarksburg, Ohio, a graduate of Starling Medical College, Columbus, in 1850, died at his home on November 15, aged 91 years.

Dr. Thomas W. Smith of Kiefer, Okla., a graduate of the Hospital College of Medicine, Louisville, Ky., in 1900, and a member of the American Medical Association, the Oklahoma State Medical Association, and the Creek County Medical Society, died in a hospital in Tusla, Okla., on November 10, aged 42 years.

Dr. George W. Parr of Geuda Springs, Kan., a graduate of the School of Medicine of the Western Reserve University, Cleveland, in 1868, and of Bellevue Hospital Medical College, New York, in 1876, died at his home on November 19, from pneumonia, aged 75 years.

Dr. Charles Gray Cole of Binghamton, N. Y., a graduate of the Albany Medical College in 1897, and a member of the American Medical Association, the Medical Society of the State of New York, the Broome County Medical Society, and the Binghamton Academy of Medicine, died at his home on October 27, from pneumonia, aged 51 years.

Dr. Samuel Erskine McClymonds of College Springs, Ia., a graduate of Miami Medical College, Cincinnati, in 1877, died at his home on November 17, aged 64 years.

Dr. Jesse M. Ledbetter of Shreveport, La., a graduate of Charity Hospital Medical College, New Orleans, in 1876, died at his home on November 9, aged 62 years.

Dr. Robert L. Walker of Carnegie, Pa., a graduate of the School of Medicine of the University of Pennsylvania, Philadelphia, in 1866, and a member of the Medical Society of the State of Pennsylvania, and the Allegheny County Medical Society, died at his home on November 19, from pleuro-pneumonia, aged 78 years.

Dr. George E. Nickel of Belle Vernon, Pa., a graduate of the Physio-Medical Institute, Cincinnati, in 1881, died at his home on November 13, aged 57 years.

Dr. Onas Smith of Ash Grove, Mo., a graduate of the St. Louis College of Physicians and Surgeons in 1904, died at his home on November 15, following an operation, aged 33 years.

Dr. Andrew James Park of Oak Park, Ill., a graduate of the Medical School of Harvard University, Boston, in 1852, died on November 25, from senile debility, aged 90 years.

Dr. Oliver Herman Heidt of Detroit, Mich., a graduate of the University of Michigan Medical School, Ann Arbor, in 1915, died in Harper Hospital, Detroit, on November 23, aged 26 years.

Dr. John A. Warner of Clarksville, Mich., a graduate of Saginaw Valley Medical College, Saginaw, Mich., in 1901, and of the Detroit College of Medicine and Surgery in 1908, died in Chicago on November 5, aged 51 years.

Dr. Edwin Hunt Robinson of Robinson Springs, Ala., a graduate of Memphis Medical College in 1849, died at his home on November 22, aged 89 years.

Dr. David Claytor of Bedford, Va., a veteran of the Confederate Army, died at his home on November 17, aged 84 years.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

SANITATION OF CAMPS—WIND OF THE BULLET—FUNCTIONS OF THE CEREBROSPINAL FLUID.

London, Nov. 18, 1916.

The Epidemiological Section of the Royal Society of Medicine has had under consideration the sanitation of camps introduced by Capt. C. G. Moor, who after describing the organization of a sanitary section dwelt upon certain aspects of sanitary work at a base: as to water supply, he would cooperate with the civil authorities and so secure double sterilization, as the men's water bottles would be systematically dealt with at the same time. In disposing of horse manure, the plan he considered most satisfactory was to lay down a tram line to the yard at a gauge of 18 in. and a weight of rails of 12 lb. to 18 lb. Sleepers should be not more than 2 ft. apart and properly packed. By this plan manure

could be removed a mile or a mile and a half from the camp. To burn the manure a cross-trench incinerator was best. To keep down flies when burning or close packing was not practicable, a good plan was to run fowls on the dumps, as they devoured great numbers of larvæ; to keep them from latrines close-fitting lids to the buckets were essential and also care to ensure these lids were replaced instantly after use. Very efficacious fly wires might be made of the wires of hay bales by smearing them with a mixture of two parts of powdered resin and one of castor oil, melted and applied hot. Various devices employed by the sanitary sections in the field were illustrated by Major Fremlin, commander of the City Sanitary Company. Lieutenant-Colonel Copeman insisted on the importance of close packing manure as stifling the fly pest at its source, and spoke of excellent results of chemical treatment of sullage water. Mr. Bacot, entomologist of the Lister Institute, pointed out the danger of applying results obtained with fly sprays at ordinary temperatures to tropical or subtropical conditions. Lieutenant-Colonel Kenwood hoped that many of the simple and effective devices invented under the stress of war conditions would be utilized in civil public health work in rural districts. Captain Hartley related his experience with a sanitary section at the front and showed the danger of allowing wastage in the sanitary ranks to be replaced by untrained men.

The question of the effects of the "wind of the bullet" has been again brought forward in view of the war. The problem is whether the displacement of air alone can cause serious or even mortal injuries, without the man being touched by the projectile. You will remember that Baron Larrey maintained that all the stories of men being killed or wounded in such a way were due to a false interpretation of the facts. Nevertheless, it is certain that soldiers have been rendered deaf by the explosion of a shell near them. Further, one French soldier was found dead in a field after exposure to such danger, although no splinter seemed to have touched him. This has naturally revived the question of the wind of the bullet. There does not appear to be any record of soldiers being actually killed without being touched by a solid piece of the projectile. There is, however, a great difference between the shells of to-day and those of former years. This is due to greater speed as well as the greater power of the explosive element, and results in more men being knocked out. Shells bursting near them may cause concussion of the brain or spine with violent headaches or deafness. In a case recorded by Professor Symonds a soldier walking on one side of the road was knocked down by a shell bursting on the other side, making him insensible for several days. He tells, too, of cases in which the bullet traversed the skin and caused a burning wound an inch in length. Symonds has had no case due to the wind of the bullet, but if such occurred they would be treated in the field hospitals.

Professor Halliburton's address at the Neurological Section of the Royal Society of Medicine was devoted to the "Possible Functions of the Cerebrospinal Fluid," a subject which he opened with a statement of the present state of knowledge as to the character, composition, and fate of the fluid. Under normal conditions it is clear, like pure water, of low specific gravity, contains in solution inorganic salts similar to those in the blood with a trace of coagulable protein and some reducing substance which has now been determined to be glucose; it is practically free from formed elements. Under some abnormal states the protein may be greatly increased or other substances added to it, such as cholesterol, choline, or a similar substance. Cellular structures may also be added and the differentiation of these is a valuable aid to diagnosis. Parasites of different sorts are found in other cases. The fluid is formed primarily by the secreting cells which so prominently cover the choroid plexuses in the cerebral ventricles, so that this structure was well named by Mott, the choroid gland. The fluid is normally present at a certain pressure which is not the result of arterial pressure transmitted passively. This pressure may, indeed, be influenced by either the arterial or the venous, but does not depend on these, and often varies quite independently of them. The true cerebrospinal pressure, said Professor Halliburton, is the result of the secretory pressure of the choroid epithelium cells; in other words, the craniospinal contents can no longer be regarded as a fixed quantity without power to expand or contract in volume. Three groups of substances promote the flow and increase the pressure independently of those which affect it secondarily by altering blood pressure; first group, excess of carbon dioxide (or lack of oxygen) in the blood, as in asphyxia or drugs which interfere with respiration; second group, volatile anesthetics, which may act by interfering with or altering respiration or the physical conditions of secretion; third group, this is specific and consists of an extract of the choroid gland, or of the brain; the former is the more powerful. The chemical nature of the hormone in this extract is uncertain, but it is probably some product of nervous metabolism, which, arising in the brain, passes to the choroids, accumulates in them, and stimulates the secreting cells to activity; it cannot be discovered in the normal secretion, but in general paralysis and brain softening—conditions in which catabolic processes are excessive—it can be recognized (by physiological tests) in the fluid itself. The plexuses have abundant nerves, but there is no evidence that they are secretory; probably they are not. This fluid is without doubt being formed continually. Then, what becomes of it? Neutral fluids disappear in a few minutes, if introduced into the cranio-vertebral cavity, and the course taken by them, and presumably by the normal fluid also, can be traced by chemical tests or by the physiological action. By such methods it has been proved that the exit is through the bloodstream. The speed with which such substances appear in the blood is very remarkable, especially if introduced into the subcerebellar region; *e.g.* adrenalin, nicotine, or atropine will show typical physiological action in a few seconds, almost as rapidly as if injected into the venous circulation. On the other hand, those substances not readily diffusible (*e.g.* commercial peptone) do not produce their effects when introduced into the cerebrospinal fluid, so that the old theory of valved orifices leading to the large veins at the base of the brain must be abandoned. Diffusion is most rapid in the subcerebellar district, but is extremely slow in the spinal, especially the lower spinal region, and probably occurs in the venous sinuses by the microscopic arachnoid villi—possibly also by transference through the thin walls of the blood vessels within the central nervous system. Diffusion in the opposite direction does not occur except in a negligible degree in the case of alcohol and a few drugs.

8. Ether Anesthesia. H. H. Amsden.

1. Preparedness for Health.—Haven Emerson, Commissioner of Health, New York City, makes a strong plea for preparedness for health along three avenues: The prevention of communicable diseases; the correction of habits which determine or contribute to premature death, and the prevention of industrial hazards. With relation to the registration laws for births and deaths—to our shame, be it said—we, who claim to be a civilized nation, have still so cheap a notion as to life and death that we are without a national registration law or uniform State laws demanding the reporting of births and deaths. Only 66 per cent. of the population of the United States lives in States where the registration of deaths is compulsory, and less than 31 per cent. live where registration of births is required. Emerson states that while there are the thousands killed in Europe in battle, more people are killed by preventable disease annually in this country than the annual loss of any nation in the present war. He refers to the yearly death rate in New York City, which has fallen from 29 per thousand to 14 per thousand of population, and that out of 75,000 deaths a year, 31,700 were from causes which are largely, if not wholly, preventable. We still lose 13,866 children under a year of age. But in reviewing the results obtained by the half-century experiences of the Department of Health, we find that if the death rate of 1866 had prevailed in 1915, we should have lost in New York City last year 88,000 people who are now living. The best results are shown in the infant mortality rate, which has fallen from 242 per thousand living births in 1891 to 98 per thousand births in 1915, and in the past five years from 170 to 98 per thousand births. Whereas only 80 per cent. of the babies born in 1898 lived through their first year, now more than 90 per cent. survive. He compares the work in the examination of food handlers done by the physicians of the Health Department and the results obtained by the same number of private physicians employed for the same purpose. The results showed that the departmental physicians discovered 3.7 times as many cases of pulmonary tuberculosis as the private physicians. He further states that whether by organization, by endowment, or by State employment, there must come a change in the basis of medical practice. While reviewing some of the brilliant results obtained through the efforts of the Department of Health, he also shows wherein weakness lies, and the urgent need for public and scientific cooperative medical service promptly summoned and consistently obeyed; the quick and efficient handling of contagious and communicable diseases, which make heavy inroads on lives; education in the right ways of living, from the training of the expectant mother, through the schooling of her child, and until the new home is started in the next generation; union of effort by the State, the employer, and the employee, to prevent wastage from occupational disease. Upon these principles of action must our social program for national service be built. It is not a conflict with the popular clamor for a military and naval preparedness that Emerson suggests, not a hindrance to commercial preparedness for greater national wealth, but a warning of the futility of both of these without the assurance that the first need and greatest asset of a nation, its health, should take the leading place in men's thoughts. There is nothing so democratic as disease, no bond so strong as the appeal of suffering fellowmen.

3. An Outline of the Elements and Treatment of Stammering.—Anne B. Stedman says that with the cases of structural defect, stammering is of purely mental origin; otherwise the expression in faulty speech of the neurotic temperament. Therapy must therefore be based on this fact. Two methods are used: One, used by physicians, aims to cure by working from the inside out, that is by giving all the attention to the frame of mind when speaking; the second, employed by teachers not of the medical profession, endeavors to treat from the outside in by the use of vocal exercises without regard to the mental element. Now the stammerer can produce perfectly normal consonants and vowels when unembarrassed, and practical treatment of the habit, vocal exercises, etc., are only half the battle. The treatment must go deeper until it reaches the *fear*—the emotional disturbance that occurs under trying circumstances between the thought and its expression. It is here that the training of a neurologist is required, as stammering is as truly the province of the neurologist as any other nervous affection. The layman in teaching this condition narrows his field and must depend on the personal touch. Often, to tell a child who is constantly bracing himself for difficulties, that he need not do the things he dreads, is followed by surprise, gradual relaxation, and a new perspective, which is a great help to normal speech. In a public clinic this plan cannot be carried out, so class treatment must be resorted to, which is of inestimable benefit in many ways, but aside from benefit to the stammerer it shows to the teacher the weak spot in the patient's progress, and then improvement, though frequently hard won, is no longer superficial. Elemental speech exercises, principles of singing, elocution, and phonetics, breath control, and relaxation are methods all employed. These cannot be followed out alone at home, no matter how conscientious the pupil; the newly acquired mode of speech must be used constantly until it becomes mechanical. In the majority of the patients, character plays an important part in recovery. Will, perseverance, and ambition make up the final third when a patient has been brought two-thirds of the way toward normal speech. Besides the above mentioned aids, a change has to be brought about in the patient's attitude of mind; something has to relax, to let go before the force of ambition can even be appealed to. Character—moral force, that is—is not synonymous with mental makeup, and it is the stammerer's mental makeup, for which he cannot be held responsible, which is at the bottom of his trouble. Cure the habit, but cure the mind as well.

7. An Expedient for the Radical Cure of Some Retroversions.—Edward Reynolds makes special reference to the cases of women who between pregnancies suffer from retroversion, yet for whom an operation is not indicated, but the wearing of a pessary between pregnancies becomes necessary. He gives his treatment as follows: All that is necessary to secure effective puerperal involution of the supporting structures, and a cure of the retroversion, is so to arrange the puerperium that the supporting structures undergo involution, and complete involution, while the uterus is held in an extreme forward position. Under these circumstances

the supporting structures will almost invariably shorten and resume firmness to a degree which will hold the uterus permanently in a normal position. At a period in the puerperium at which the uterus is too large to be capable of retroverting, *i.e.* between the tenth and fifteenth day of the puerperium, the uterus should be thrown into strong anteversion bimanually, and a carefully fitted, hard rubber pessary should be made to hold it there. Such a pessary will usually be larger than the stock sizes and must often be specially procured. Very hot vaginal douches should then be administered twice daily. From two to four quarts should be used, and the injection should last from fifteen to twenty minutes. It should be given with a fountain syringe and under a fall of not more than twelve to fifteen inches in order to avoid forcing fluid through the open os. In this position of the uterus and under the influence of the hot douches involution is usually very rapid. In most cases it will be found that within a week the original pessary will have become too large and too highly curved for the contracting vagina. A second and smaller, but equally well fitting, pessary should then be adjusted, and the douches continued. This will usually need to be replaced by one of lesser size in from ten days to a fortnight, and after a few weeks this must again be reduced. The hot douches should be continued until the uterus is but little above the normal size and firmness, but should then be intermitted, as too long a continuance of the douches sometimes results in hyperinvolution, which might cause subsequent dysmenorrhea.

1. Gonorrhea a Curable Scourge.—George A. Wyeth states that the modern means at the command of the physician are so definite and precise that it is inexcusable for a case of gonorrhea to remain uncured. He does not suggest that it is a simple or easy thing to fight the gonococcus, but painstaking care in diagnosis and definite location of the lesion are now possible. Until a short time ago both profession and laity joined in considering gonorrhea an unimportant affection, while the seriousness of syphilis was early recognized. He considers it gratifying that certain of the daily papers are lending their columns to the fighting of this dread disease, for only by education can headway against it be made. Gonorrhea is a *preventable* disease, as has been amply proved in the U. S. Navy. Gonorrhea can be aborted in the majority of cases if seen within twenty-four hours after a purulent discharge has begun, except in primary cases. While it is not the object of his paper to give detailed treatment, general principles may be outlined as follows: First, definitely to locate the seat of infection and treat it locally by irrigations and applications. Here, too, mild solutions of protargol have served us well. Wyeth wishes to emphasize the importance of the systematic use of the microscope in treating this disease; first from a diagnostic standpoint. Surely no one can say positively of any given case of urethral discharge that the cause is gonorrheal unless gonococci are demonstrated. More than once has it been his pleasing experience to convince a patient who thought himself infected with gonorrhea, that his belief lacked foundation. Since there can be no hard and fast rule as to the duration of an attack of gonorrhea, the physician is, and must be dependent upon the microscope for definite information as to the progress of his patient. In conclusion, Wyeth quotes from Dr. George Luys, of Paris, who says in his "Traité de la blennorrhagie": "Our therapy is nowadays so perfect that it is not permissible for a medical man to allow a case of gonorrheal urethritis to go on without curing it. Modern science has made such conquests that we can say without exaggeration that there is no inflammation of the urethra which cannot be cured completely by appropriate treatment. But it should not be forgotten that this result is obtained only by means of prolonged and painstaking observation and that urethroscopy alone enables us to diagnose the local lesions with accuracy, and to apply the sovereign remedy correctly. Without the control of his eye it is impossible for the medical man to select the best and most efficacious treatment."

3. A Further Report on Thromboplastin Solution as a Hemostatic.—Alfred F. Hess refers to his report given about a year ago from the Research Laboratory, Department of Health, New York City, and a little later another report on the same subject from Cronin, both published in *The Journal A. M. A.*, on the experimental work done with thromboplastin as a hemostatic. During the past year Hess has continued his clinical experiments at the Research Laboratory, Department of Health, New York City, along this line together with laboratory tests to determine more fully the various properties of thromboplastin. Since an account of the first report was given in these columns, it is only necessary to give now his later results. Thromboplastin solution has been supplied to several of the maternity hospitals of New York City, where it has been employed locally in cases of melena neonatorum, in bleeding from the cord, skin, mouth, vagina, etc., and also as a dressing where there was undue hemorrhage following circumcision. Thromboplastin should be applied directly to the bleeding area; clots should first be removed. Hess reports the following results from his latest investigations: Tissue juice made from brain (thromboplastin solution) has proved itself of practical value in controlling hemorrhage wherever it can reach the site of bleeding. In cases of true hemophilia it may be regarded almost as a specific hemostatic. It is to be recommended for local use in the bleeding of the newborn, in nasal hemorrhage, and in the parenchymatous bleeding associated with various operations, etc. Where local applications fail, it should be injected into the site of hemorrhage, as in bleeding from the gums following tooth extraction. This method can readily be resorted to, as thromboplastin solution loses but little of its potency as the result of dilution and cursory boiling. Further clinical experience is necessary before

its value can be determined as a hemostatic in connection with hemorrhage of the gastrointestinal tract. However, it is innocuous when given by mouth in considerable dosage, and would seem to be indicated in bleeding from the stomach and from the upper intestine. In addition to its hemostatic action, this tissue extract has been found to possess healing properties, actively stimulating granulation tissue and hastening epithelization. It is therefore applicable as a dressing for torpid ulcers and for sluggish wounds.

5. **The Problem of Diphtheria Carriers.**—Sophie Rabinoff found in her investigations during an outbreak of diphtheria in an institution caring for 400 children in New York City that in the group of eighty diphtheria carriers which were studied, it was found that a certain number became negative, irrespective of the treatment employed. No better results were obtained with iodized phenol or with Fullers' earth, than with the silver preparations or other antiseptics. Indeed, those cases which were not treated in any way did equally as well. An exception must be made only as regards the results obtained with Fullers' earth in adults, which were fairly satisfactory. The real problem of the carrier lies in the ultimate group in which the bacteria persist in spite of all local treatment. The presence of a foreign body in the nose may provide a favorable environment for the growth of the diphtheria bacilli. Removal of tonsils and adenoids seems to offer a safe and rapid method of eliminating diphtheria bacilli from the nose and throat of carriers, and should finally be resorted to where other methods have failed.

11. **Streptococcus Infection as a Cause of Spontaneous Abortion.**—Arthur H. Curtis states that the object of his report is to produce evidence which will be helpful in the solution of the problem of definite cause or causes of spontaneous abortion from infection. It is already known that the *Treponema pallidum* is directly responsible for the death of the fetus in the later months. From thorough experimental and clinical work carried on in the Pathological Laboratory and Gynecological Service of St. Luke's Hospital, Chicago, he offers the following report as a summation of his work thus far: From the urine of a patient who gave spontaneous birth to a stillborn child were obtained large numbers of streptococci. Two pregnant rabbits were intravenously inoculated with cultures of this organism. Death of the fetuses followed. One mother appeared to be in normal health, the other became seriously sick some days after the death of the fetuses. Pure cultures of the streptococcus were obtained from the kidneys and from the uterine contents of both animals. From a spontaneous stillbirth were obtained pure cultures of a Gram-positive streptococcus. A series of three pregnant rabbits was intravenously injected with washed cultures of this organism. In each instance there was premature labor or death of the embryos with absorption. Serious maternal illness was not evident. At necropsy, pure cultures of the streptococcus were recovered from the uterine cavity. Whether organisms other than the streptococcus possess the power of interrupting the course of pregnancy does not materially influence these results. These facts remain: Streptococci can be isolated from women who give spontaneous birth to stillborn children; streptococci have been obtained in pure culture from the placenta and from the stillborn fetus; intravenous injection of pregnant rabbits with cultures of these streptococci is followed by fetal death; the streptococcus can be isolated in pure culture from the fetus and from the uterine cavity of the mother rabbit. The streptococcus encountered in these cases appears to be peculiarly adapted to infection of the genitourinary tract. Several closely related, probably identical strains, have been isolated from patients with uterine, tubal, and kidney infections. Possessed of certain variability in cultural characteristics, these strains have much in common. We may have here to do with a type of streptococcus especially modified by, and with especial affinity for, growth in the genitourinary tract; it is characterized by persistence of infection, low virulence, and richness of growth on artificial mediums.

1. An Inquiry into the Natural History of Septic Wounds. Section III. Kenneth Goadby.
2. A Note on the Value of Vaccine Therapy in the Treatment of Gunshot Wounds, Viewed from a Surgical Aspect. R. H. Jocelyn Swan.
3. The Psychology of Malingering and Functional Neuroses in Peace and War. Thomas Lumsden.
4. The Angle of the Dropping Pipette and Accuracy in Agglutination Technique. R. P. Garrow.

1. **An Inquiry into the Natural History of Septic Wounds.**—Kenneth Goadby gives an exhaustive account in the third section of his report, covering tissue reactions. The first two sections previously published contained certain facts relating to sinus formation and sinuses and vaccine therapy. His conclusions from this last extensive work are drawn as follows: (1) That the energy dissipated in the tissues from projectiles produces changes in a wider area than that immediately lacerated by the projectile itself. (2) That the cellular activity promoting repair in the affected areas proceeds concomitantly with degenerative processes; with the degenerative processes are associated anaerobic bacteria, *B. perfringens*, B. malignant edema, and possibly B. Hibler IX type. (3) That there is direct histological evidence of tissue digestion, in addition to necrotic changes due to traumatism or coagulation owing to interference with circulation. Evidences of degenerative tissue changes are found in tissue removed from wounds at long periods after the original infection of the wound. (4) That acid production by anaerobic bacteria of the perfringens class is an important factor in the determination of clinical gas gangrene. (5) That the general blood reaction in the direction of leucocytosis is more related to infection with the pathogenic cocci than the anaerobic bacilli. In the three sections of the present report an attempt has been made to correlate certain facts obtained in the course of an inquiry as yet uncompleted. The bacteriological data as to the organisms occurring in the depth of the sinus have been confirmed by direct examination of the tissue concerned. The bacteriological evidence of sequestered organisms in the sinus walls of "flare" cases also receives striking confirmation from the histological examination. The evidence adduced confirms the opinion previously expressed that the organisms remaining in the tissue retain their activity and potentiality for disease. Theoretically there is further evidence that the use of vaccine therapy of appropriate antigen is of advantage in combating the infections. No drainage in the ordinary sense of the term can easily affect the contorted intricacies of a sinus passing first of all into bony tissue and thereafter radiating in several directions; it is in this type of wound, or rather sequelæ to a wound, that the bacteria are found lodged in the tissues, partially shut off from the action of the living cells. Operative interference sets them free; they may, and do, reinfect the surrounding areas, and to raise the patient's resistance to such disability is clearly a therapeutic step of supreme importance.

2. **The Value of Vaccine Therapy in the Treatment of Septic Gunshot Wounds.**—R. H. Jocelyn Swan has continued his studies of vaccine therapy with reference to septic gunshot wounds with Goadby, the writer of

the foregoing article. Swan says that while the future course of vaccines naturally depends upon the examination revealed in the individual wound, he directs that every case of septic wounds arriving from overseas shall receive an initial dose of a mixed polyvalent vaccine of proteus and streptococcus until the true bacteriology of the wound can be worked out and before any surgical measure, other than freely incising the wound to secure adequate drainage, is adopted. It is only in a comparatively few cases that a mixed infection containing the above named organisms will not be found, and he impresses upon readers the importance of making an examination of both the superficial and deeper aspects of the wound, for he has found frequently that the deeper part of the wound only will give the true indication of anaerobic activity. In selected cases operative interference of some sort is necessary as an urgent measure before vaccine therapy can be given, and these are the cases that are so frequently followed by pyrexia 102°—103° F. for from twenty-four to forty-eight hours, whereas similar cases in which vaccines have been used usually show no pyrexia even when anaerobic gas-forming organisms were proved to be present in the depth of the wound. Since radiographic examination is always necessary for knowledge of hidden bone and tissue condition and the presence of metal fragments, it is this time that is so valuable in an attempt to immunize patients against the proteus and streptococcal infection, and should be done in all cases. Swan has found the greatest value of vaccine therapy in the treatment of complicated septic fractures of long bones and of fractures which open into joint cavities. In the treatment of septic compound fractures is made a routine practice of giving a preliminary dose of polyvalent vaccine (proteus and mixed streptococci), and then after two or three days freely open the wound to secure adequate drainage, approximating the fragments and only removing those fragments which are undoubtedly completely separated, at the same time taking advantage of the opening of the wound to obtain further bacteriological examination. Extension apparatus of various types or splints suitable to the individual fracture are applied, but should the resulting position of the fragments prove on further radiographic examination to be unsatisfactory, he has no hesitation, after a further few doses of specific vaccine, in securing the bone fragments in apposition by means of silver wire or even bone plates in the presence of sepsis, and can now look back on a series of cases in which not only have limbs been saved, but bones in good alignment and functional use. Further, the result as regards sinus formation and necrosis of fragments of bone in the seat of fracture has been more appreciably lessened in those cases in which vaccines have been used than in those in which exactly similar surgical measures were employed without the assistance of vaccines. In the treatment of septic gunshot fractures which involve a large joint, vaccine therapy holds an important place. In these cases he has obtained a freely movable and serviceable limb, and a much better result than after excising a fixed joint after the wounds have healed, when the tissues around the joint are so matted by the long-continued suppuration. Another feature is the freedom from secondary hemorrhage in cases treated with a polyvalent proteus and streptococcal vaccine. Whereas before its use secondary hemorrhage was not uncommon in septic wounds, no case under his care has occurred where vaccines have been employed. It seems probable that the control of the proteus and streptococcal infection arrests the digestive action in the tissues of the anaerobic coexisting infection. He cannot venture to discuss the bacteriological problems involved, but is convinced of the great use of vaccines as a supplementary treatment to surgical measures in septic wounds, and is satisfied that the routine employment of a polyvalent vaccine of proteus and streptococcus is of value in inhibiting the tissue-necrosis caused by anaerobic bacilli, which are so commonly associated with these organisms in gunshot-wound infection.

1. An Investigation Concerning the Disinfection of Meningococcus Carriers. M. H. Gordon and Martin Flack.
2. An Experimental Study of the Cultural Requirements of the Meningococcus. H. M. Gordon, T. G. M. Hine, and Martin Flack.
3. Epidemic Cerebrospinal Meningitis: Its Bacteriology and Pathology. W. J. Denehy.
4. Observations on the Treatment of Cerebrospinal Fever. C. Worster-Drought.

1. An Investigation Concerning the Disinfection of Meningococcus Carriers.—Gordon and Flack state that in all outbreaks of cerebrospinal fever where bacteriological investigations have been made, carriers have been found greatly to outnumber the cases; even then the extent of the carriers of the true organism has been somewhat overestimated. By application of the agglutination test, based upon a study of meningococci isolated from the cerebrospinal fluid of over 200 of the actual cases, and applied throughout in a strictly quantitative fashion with suitable controls, the number of persons who would otherwise be identified as carriers merely because they harbor in their nasopharynx an organism resembling the meningococcus is reduced by as much as 30 to 40 per cent. But even with this precaution, the number of carriers considerably exceeds the number of cases. Thus from contacts of sixteen cases ninety-two carriers were found in a recent outbreak. Dry warm weather with sunshine apparently has some beneficial influence in enabling carriers to become free, and cold, damp, sunless weather the opposite. How far this apparent influence of the weather is due to its effect on the secretion of the nasal mucus, remains to be seen. Now the meningococcus is one of the least resistant of all pathogenic bacteria to disinfectants, and it is rapidly destroyed by some of the mildest of these bactericidal agents in concentrations easily tolerated by the mucous membrane of the nasopharynx. Theoretically, therefore, the meningococcus should be destroyed in the nasopharynx with ease if only it could be reached there by a suitable disinfectant. The means employed for applying disinfectants locally has consisted up to the present chiefly of hand sprays and douches. It seems needless to mention that these means have not proved successful, especially in the treatment of chronic carriers, for all the organisms could not be reached on the nasal mucous membrane. The object of these experiments was to find a disinfectant and to apply it to the nasal membrane in the form of a vapor, reaching the necessary parts in a fine shower of droplets. Experiments have been made with a considerable number of disinfectants, but the ones of which chief use has been made so far are chloramine 1 to 2 per cent., or zinc sulphate 1.2 per cent. Eusol was tried, but was found more irritating and less efficient for the present purpose than the substances named. The cubic capacity of the room in which the carriers have been subjected to treatment with the spray has been reduced, by means of a canvas ceiling, to 750 cubic feet. One liter of the solution of disinfectant is sprayed into this area in the course of fifteen to twenty minutes. The carriers remain in the room during the whole of that time, inhaling the air through their nostrils. Thirteen men were subjected to the treatment with chloramine, ten of whom were found free of the organism after from four to thirteen days. Three re-

maining showed either neurotic symptoms or failed to inhale properly. As a result of more extensive work than can be given here, Gordon and Flack consider that these observations have led us to belive that, in the case of carriers of the meningococcus, prognosis with regard to the duration of their future period of carrying varies largely with the degree to which their nasopharyngeal secretion is infected by the meningococcus. In our experience, the majority of carriers whose nasopharynx yields only a few colonies of the meningococcus clear up quickly. In the case of these persons good results follow local treatment either by direct application of a 1 per cent. solution of chloramine, or by subjecting them to inhalation of a steam spray charged with zinc sulphate. On the other hand, carriers whose nasopharyngeal secretion yields a copious growth, or a practically pure culture of the meningococcus, are often far more difficult to cure. The results on these persons with zinc salts were disappointing, but they served to emphasize the success of those obtained with chloramine, which, though still somewhat few in number, are more than encouraging, and would appear to indicate that a large proportion of these chronic carriers can be definitely freed of the meningococcus by this form of treatment in a comparatively short space of time. We would add that while these observations on meningococcus carriers were in progress, several cases of chronic nasal or postnasal catarrh have been submitted to disinfectant treatment by the automatic steam spray. As in all of these persons improvement has resulted, we offer the suggestion that this method is worthy of trial on a larger scale for the treatment of such cases.

October 17, 1916.

Diagnosis of Weil's Disease.—Professor Bäumler takes up this subject in detail, describing one case at great length and speculating on its nature. The resemblance to yellow fever is marked and a corresponding cause is suggested. In the former the blood is infectious for the first three days, while in Weil's disease infection may be conveyed by the first day to animals. The guinea pig shows the same disease as man. In Weil's disease the period of infectiousness of the blood may extend to the tenth day. Uhlenhuth and Fromme have isolated a delicate, slender spirochete from the blood and tissues of infected guinea pigs. Krumbein and Frieling have shown that the flea can convey the disease from man to the dog. Rare among the civilian population Weil's disease appears with epidemic incidence in the troops. In the author's 50 years of hospital and consultation practice he has seen but one case of Weil's disease, as described by Weil. Of many cases of icterus gravis seen by him not one could have been confounded with the former, with a solitary exception, which was seen 22 years ago. During the first 3 days the resemblance to Weil's disease was striking, but the temperature persisted and the icterus and renal symptoms were unusually severe; it was four months before the patient recovered. He still lives and is earning his living. All this history speaks strongly against icterus gravis which Bäumler regards as a sepsis proceeding from some infection of the liver or gall-ducts. Had the guinea pig test been available at that period such a condition could have been readily excluded. The case history is now reproduced from the hospital record of 1894.

Lung Tuberculosis or Lung Syphilis?—Wilmars describes 8 cases in which this question had to be decided. All were regarded eventually as examples of pure lues, but the author quotes others in which both diseases were associated. Patients with pure pulmonary lues may be admitted into tuberculosis sanatoria where they do not belong. A positive Wassermann reaction cannot exclude tuberculosis in such cases. Absence of tubercle bacilli in extensive pulmonary disease in association with syphilitic history or stigmata of that disease means that intensive syphilis therapy should be practised. Of great value in diagnosis is the presence or absence of fever. A patient may have emaciation, night sweats, cough, and bloody sputum, but if he has no temperature syphilis should be suspected. Tuberculin as a diagnostic test is mentioned in but one case. These patients often do surprisingly well on potassium iodide. In cases of association of both diseases the presence of tubercle bacilli and positive Wassermann will often make the diagnosis, but in closed tuberculosis the bacillus may not be found. While the author has found a positive Wassermann in all of his mixed cases, others have not been so fortunate. He would place all subjects with tubercle bacilli and fever in the sanatoria and would keep all others out. He closes by quoting from a well-known syphilographer to the effect that in many cases an autopsy alone can explain the true mechanism, *i.e.* to what extent is one disease determined by the other?

Case of Pulmonary "Calculi."—Helbig describes a case of this clinically rarest of affections, which is termed in German *Steinhusten* because stones are coughed up by the victim. Autopsy finds are not included, for these are not so infrequent; but of clinical cases few have ever been placed on record. In the most recent, reported by Bickel and Grunmach, the stones were no larger than a pea. The author's patient was a woman of 58, healthy until recent years, when she began to suffer with symptoms suggesting influenza. During the first attack no "stones" were coughed up, but during a second visitation she began to expel small "stones." She has never since been entirely free from cough. A third attack of "influenza" one year after the preceding led to paroxysms of coughing, with dyspnea, and finally in expulsion of what she termed a "bone." About 8 months later a fourth attack culminated in a like manner, while at the end of another two weeks a fifth seizure brought the patient for the first time under medical care. She brought with her four of the "stones," two of which were as large as hazel nuts. An *x*-ray showed two circumscribed shadows in the lung which doubtless represented unexpelled "stones." Miscroscopic section showed the presence of bone corpuscles and lamellæ in all the foreign bodies. This surprising find really furnished an explanation of the whole disease process which must have been tuberculous. The patient had developed latent calcified foci of the disease, which in turn had led by processes known to pathologists to a metaplasia of osseous tissue as a result of constant irritation of the fibrous capsule of the focus. The "stones" expelled were in reality osseous tissue. While a "stone cough" may be a reality, the present case should be termed "bone cough."

Cause and Transmission of Volhynia Fever.—According to Töpfer the five day or Volhynia fever has not yet been proved to be due to a parasite, although the circulating blood of the patient can convey the disease. The author inoculated guinea pigs intraperitoneally with human blood and obtained a fever curve identical with that caused under the same conditions by typhus. Transmission by the body louse is therefore the most probable cause and the author has studied the insects from that viewpoint. As a result he found organisms which were readily distinguished from the supposed exciting cause of typhus despite considerable resemblance. Notwithstanding the clinical differences between the two fevers, it is not improbable that clinical typhus

may really be at times the result of mixed infection. From analogy the cause of isolated five-day fever should be a protozoan (recurrent character as seen in relapsing fever); but it seems that this view must now be abandoned.

Acute Urethritis Due to the Streptobacillus Urethræ of Pfeiffer.—According to Engwer this microorganism, first described by Pfeiffer in 1904, may exert a pathogenic action, but only in cases of prior acute gonorrhea or actual gleet. With a soil thus prepared the streptobacillus, naturally a saprophyte, can cause a special form of urethritis. If chronic gonorrhea is already present a symbiosis results. The streptobacillus can then cause a genuine bacterial urethritis with increased secretion and exacerbation of the clinical behavior.

Retransfusion in Abdominal Hemorrhage.—According to Kreuter attempts were first made about two years ago to restore to the circulation the blood lost in internal hemorrhages. The subject had a good experimental basis and quite recently the author attempted its application to a wounded soldier who suffered from profuse intraabdominal hemorrhage following projectile wounds of the liver, spine, and one kidney. Laparotomy was at once performed, and while much blood escaped in clots, the fluid portion was allowed to absorb in sterile compresses and was also washed out with saline infusion. The soaked compresses were squeezed and the escaping blood was passed through a filter into the irrigation-blood. In this manner a liter of clot-free blood was quickly obtained. The lower abdomen and pelvis contained an abundance of thick clots and the total loss of blood was estimated at from 2½ to 3 liters. With patient moribund blood was transfused into an elbow vein, 15 minutes of time being required for the operation, in addition to 20 minutes required for laparotomy, etc. The abdomen was cleansed and closed during the transfusion. The immediate effect was marvelous, but another hemorrhage followed from the wounded kidney and death soon occurred.

Leeches in the Larynx.—Härting, who is serving in the Balkan campaign, had among his first Turkish patients three with "worms in the throat." He was unable to converse with these soldiers, and his first diagnosis was ascarides in the pharynx as a result of vomiting. Cathartics were ordered. Next day the men were spitting blood and the diagnosis was changed. The laryngoscope showed in each patient a dark blue mass below the vocal cords. The men were told to gag, which act raised the larynx and enabled the author to grasp and extract the parasites. The grateful patients nearly smothered the doctor with hugs. The soldiers had recently drunk from a puddle of water while suffering greatly from thirst.

La Presse Médicale.

November 2, 1916.

Acute Azotemic Nephritis in the Troops.—Ameuille states that in civil practice acute nephritis *a frigore* is of rare occurrence. Since the outbreak of the war it has become so common that up to the end of June, 1915, 1,062 cases had been recorded in the French expeditionary force, and we know now that it is abnormally frequent throughout the entire army. It appears to increase in frequency as the war is prolonged, and is now known to be independent of atmospheric conditions, while still of the type of nephritis from exposure—anasarca, massive albuminuria, uremic symptoms mild in character. But there are other cases without edema but with a variety of symptoms pointing to the kidneys. Such cases the author terms acute azotemic nephritis. Concerning the latter surprisingly little is known. Hogarth has recently noted its occurrence in the English troops under the name of acute nephritis without edema. We see fever, hematuria, albuminuria, and evidences of infection. The blood shows nitrogen retention. The affection may begin as a simple fever and devoid of symptomatology. Typhoid would perhaps be first thought of, but the occasional presence of remissions opposes this possibility. Moreover the temperature rises suddenly and not gradually, with oscillations more marked. The vomiting which may set in is too marked and persistent for an ordinary infection. Headache may be persistent and violent. Certain cases begin with an angina or other local manifestation. The diagnosis may be grippe or bilious attack or merely a general feverish cold with muscular soreness and stiffness. Then it will be noted that the urine is scanty and perhaps bloody. The diagnosis of acute nephritis is evident through the presence of formed elements of blood in the centrifugalized sediment. Mere presence of albumin means nothing in febrile and hematuric cases. A blood test for urea is alone of value in prognosis, and if the proportion increases a fatal outcome is assured. In nearly every case seen cough and expectoration were noted and sonorous rales heard over the chest. The liver is sometimes sensitive to palpation and slight icterus may occur. Acute nephritis with icterus has been seen by a number of observers. Severe headache and meningism point to increase of nitrogen in the blood. In some cases convulsions have been mistaken for epilepsy. In one such case the amount of urea per liter of blood was 2.55 gms. The course of the disease varies greatly. It may be short and fatal, short and benign, and may be long, usually with complete recovery, but often with some persistence of ill health. When both fever and albuminuria are absent we have only the blood to guide us. The purely azotemic type attacks the patient "brutally" and he may not recover from its impetus. The onset of the edematous type is less brutal but more profound; life is not so much menaced for nitrogen retention is less and quite constant. Still the dropsical and nondropsical forms are manifestations of one disease—"war nephritis." When a subject dies from acute azotemia signs of an old renal lesion may be found, with the superaddition of acute intestinal nephritis. Practically the histology of the kidneys is the same in both diseases. Something about prolonged trench life damages the resisting power of the kidneys and the active cause is doubtless microorganisms in every instance, although this point has not been demonstrated beyond doubt.

Revue Médicale de la Suisse Romande.

October 20, 1916.

Infrequency of Extrapulmonary Tuberculosis Under Tropical Sunlight.—Steiner speaks only of Java, where he has practised for 20 years. Pulmonary tuberculosis is common enough, alike in the aborigines and various foreigners. No race or class has any immunity. But it is most rare to encounter white swelling of the knee, hip disease, scrofulous glands, scrofulous ophthalmia, etc. These conditions are the very ones which benefit by heliotherapy in the North. The Javanese live in almost perpetual sunshine, for in the rainy season the rain seldom appears before 4 p. m. Only the Europeans are protected from the solar light and heat, but these are lightly clad and partly exposed to solar rays; much more in fact than during the European summer, especially in childhood. The country is by no means salubrious, and typhoid, cholera, dysentery, ankylostomiasis, and malaria flourish. The bubonic plague has of late years become familiar. Cleanliness is hardly understood. The natives expectorate everywhere.

Bathing is common but only as a refreshment. Food is ample—rice, fish, and legumes with not a little meat. The Europeans and Chinese seem alone in the use of alcohol. There is no milk industry. Cows' milk seems plentiful but is little used as a beverage, save by European children. It is by no means good milk, but can hardly contribute to the spread of pulmonary tuberculosis because of the absence of extrapulmonary forms which are usually associated with a possible bovine transmission. Whether or not the so-called scrofula is directly related to eventual pulmonary tuberculosis, every child (and nearly all are believed to have latent tuberculosis) ought to have the benefit of heliotherapy. During the warm months the skin should be exposed as much as possible to the sun—at least 50 per cent. of the surface. The Javanese certainly gets plenty of fresh air, both because he is outdoors so much and because the loosely built houses are ventilated automatically. The inside air, however, is smoky and otherwise disagreeable. The frequency of pulmonary tuberculosis in Java may perhaps be accounted for by the lack of sanitary knowledge and by conditions like malaria and ankylostomiasis which tend to lower the general resistance.

October 20, 1916.

"Cesarean Section" Due to Shell Explosion.—Saint, Goehlinger, and Poiré relate the case of a woman who lived in a town on the British front which was under daily bombardment. She was 33, and 6 months' pregnant when a fragment of shell exploded in the street, injuring her abdomen. When first seen there was a marked peritoneal defence toward the right. The uterus was anteverted and its highest point was two fingers breadth above the navel. Attempts to palpate the fetus failed because of pain and defensive reaction. The shell fragment had passed through the abdominal cavity, the points of entrance and exit being close together. The woman bled freely from the vagina, and a wound 5 cm. long was found in the fundus uteri. Amniotic fluid and meconium were found in the lesser pelvis. The fetus was seen to lie in the left occipital position, presenting a slight shell wound in the lumbar region. The authors made a hysterotomy incision which conformed to the external wound and extracted the fetus and placenta, as in the ordinary cesarean operation. The premature fetus was left alone, as dead, but began to cry from exposure to the cool air. In the meantime the uterus had been sutured after careful hemostasis, the other visceri having been found intact. The infant, a female, weighing but 950 gms. and already wounded by the projectile, succumbed, perhaps for want of proper care, in a few hours. The mother made a good recovery; doubtless the presence of the fetus saved her own life by preventing injury of the intestines. The case is perhaps unique and the infant may be regarded as the "youngest victim of the war."

Cerebrospinal Commotion from Shell Shock.—Bonhomme and Nordmann mention three kinds of disorder which result from this form of shock. 1. Troubles of character. The subject becomes irritable, will not tolerate the slightest contradiction, is surprised to find himself angry without apparent cause. He is impressionable in other ways, weeps when visited by a friend, and may not be able to converse until after some time. A bold man becomes timid, begs his relatives to obtain certain simple privileges from the physician which would readily have been granted. Subjects are depressed, seek solitude, finally become melancholic. 2. Troubles of intellect. Ideation is slow and even at times incoherent; it is difficult to maintain a conversation. The confusion which followed the injury has subsided but cerebral activity is lessened throughout. The subjects, usually of a higher social plane than the average soldier, realize their condition keenly, think of suicide. Amnesia is common with inability to fix attention. There can be no improvement until this symptom vanishes. 3. Somatic disturbances. Headache is very common, with vertigo and insomnia with hypnagogue hallucinations. The body tires readily, as well as the mind. Attempts at work lead to tremor, pains in the limbs, etc. Sexual desire is usually abolished. Horror of noise is often present. To sum up the picture corresponds with that of Erichsen's "railway spine" and post traumatic neurosis of civil practice. There is nothing pathognomonic about shell shock as compared with physical shock from severe shell injury, which is of course largely psychical. After a number of weeks the patient while "convalescent" still suffers a good deal and his state may remain stationary. The patients classed as "improved" may recover completely in time. These represent averages, for there are some rapid recoveries, while some patients may not even show improvement for many months. The so-called stationary case may after a variable time, perhaps several years, proceed to recovery.

Le Progrès Médical.

November 5, 1916.

Glandular and Humoral Repercussion in Shock.—Loeper and Verpy state that these manifestations are as yet but little known while by no means rare. The majority of "commotionists" treated by the authors were asthenic and for a few days incapable of any effort. Another symptom is absolute anorexia. Not much urine is voided and constipation is the rule. Lowered blood pressure is seen in two-thirds. The entire picture can be explained by adrenal insufficiency, and if adrenalin is given the picture tends to disappear. The adrenals may be thus affected through a nervous mechanism or perhaps by direct violence over the loins, in which case renal hematuria should coexist. The anorexia may be attributed to various anomalies of gastric secretion arising in part through the vagus. The pancreas may also be affected through the effects of shock on the central nervous system, while the disturbed nitrogen coefficient in the urine is characteristic of hepatic disturbance. The blood is profoundly modified in these shock cases, although the individual variation may not be marked. Bloodsugar is abnormally low after the day of the injury. To sum up, the digestive organs, adrenals and blood all suffer from the rudeness of the central nervous shock.

A New Adjuvant Remedy for Tetanus.—Lopez reports a cured case of tetanus in which the substance diallylmalonylurea was used to replace chloral. The case was one of delayed outbreak and serum along with chloral showed no power whatever over the convulsions. The new remedy was substituted for chloral and notable improvement followed with prompt recovery. The amount of serum given was but 240 ccm. The new substance is known to be a hypnotic and nerve sedative. It may be able to replace chloral and is free from some of the latter's drawbacks.

Posttyphoid Ocular Paralyses.—According to Ginestous, not over six or seven cases of this complication are on record. The common motor nerve is the one chiefly involved. In two cases the sixth nerve was affected. In one of the latter the complication appeared during the course of the disease. The author pushed the mixed treatment in his case, which proved to be incurable.—*Le Caducée.*

Book Reviews.

A Practical Treatise on Disorders of the Sexual Function in the Male and Female. By Max Hühner, M.D., Chief of Clinic, Genitourinary Department, Mount Sinai Hospital Dispensary, New York City; formerly Attending Genitourinary Surgeon, Bellevue Hospital, Outpatient Department and Assistant Gynecologist, Mount Sinai Hospital Dispensary, New York City; Member, American Urological Association, American Medical Association, New York Urological Association, Fellow of the New York Academy of Medicine, etc.; Author, "Sterility in the Male and Female and Its Treatment," etc. Price, $3. net. Philadelphia: F. A. Davis Co.; London: Stanley Phillips, 1916.

Dr. Hühner's book gives the impression of the republication of a number of papers on this subject which he has cemented together and put in a permanent form. Thus cases are reported and the same statement appears often in various parts of the book, giving a somewhat monotonous effect. The author succeeds in finding a physical basis for nearly all the sexual ills that flesh is heir to; usually it is a congestion of the posterior urethra, or prostatic trouble. He dismisses psychoanalysis briefly: "The ardent disciples of Freud, in their enthusiasm, are apt to be entirely too narrow in their interpretations." He further states that the cases he reports are sent to him only after the psychoanalysts have failed to help them.

The conservative, orthodox viewpoint is the one taken all through the present volume. The chapters on masturbation are especially good. It is difficult to see, however, why a chapter on enuresis was included in a volume with this title.

A Text-Book of Pathology. By W. G. MacCallum, Professor of Pathology in the College of Physicians and Surgeons, Columbia University, New York. With 575 illustrations, chiefly from drawings by Alfred Feinberg. Price, $7.50 net. Philadelphia and London: W. B. Saunders Company, 1916.

The appearance of a new text-book by a teacher of wide experience is always of interest, chiefly in the personal reaction of the writer toward his subject and in the perspective which he brings, rather than in any especial contribution by which the total matter of the particular phase of the science under consideration may be expanded; for, alter all, no one volume can contain all the facts which have been amassed, and the real originality of the book must lie in the style, classification, and necessary elimination of the less important subjects. So in this admirable but rather portly volume we have an interesting contribution to this aspect of literary psychology. The writer, with engaging frankness, states in his preface that he has freely and willingly omitted many subjects ordinarily included in the conventional text-book of pathology, that he has tried to make the etiological influences the basis of his classification, and that without making any claim for novelty, he has wished to feature, so to speak, the concept of injury as covering all activities, whether parasitic or chemical, which induce in the animal body the reactive phenomena ordinarily designated as disease. That, in our present somewhat dense ignorance of a number of conditions, this procedure leads to grave difficulties is to be expected, and the rebellious subject of tumors, of the cause of which we certainly have not the slightest inkling, is perforce promptly excluded from the classification and treated in a separate section. Even in other subjects, the etiological treatment leaves gaps; for example, if paresis and tabes are to be considered as due to the *Spirochæta pallida* alone, the query instantly arises as to the infrequency of these diseases in the negro and, also, in the white female, though syphilis affects black and white of both sexes in approximately equal numbers. Some etiological factor is missing, evidently, though the student may gain the idea that the spirochete is alone to blame. In consequence of this method of classification the reader may, also, find it difficult even with the aid of the index to complete his knowledge of certain processes. Appendicitis is included under inflammatory processes induced by bacteria; but, unless he possesses more than the average stock of erudition observable in his genus, the student will not realize that mention of the possible correlation between inflammatory lesions of the organ and the presence of oxyuris in the appendical mucosa is to be looked for in the index under the name of the parasite and not under the caption "appendix" or "appendicitis."

But these slight defects are matters of small moment in comparison to the real and positive value of the text taken as a whole. The style is so clear and admirable that the author's hope, expressed in the preface, of making a continuous story of the facts of general pathology, is excellently realized. Among the most valuable chapters are those on the blood-forming organs and on the diseases due to injuries of the organs of internal secretion. In the first, the lesions of the bone marrow are illustrated by a beautiful series of plates, some of them in color, while in the second the various clinical aspects of hyper- and hypoactivity of the hypophysis are brought out with unusual clearness, assisted by striking photographs of cases, many of them from Cushing's monograph.

The volume is brought to a close by a long and admirable chapter on tumors with many illustrations and a final summary of the modern views on etiology. The temptation to impose a new classification of neoplasms on a long-suffering scientific public is happily resisted by the writer, and as a consequence the old familiar designations now hallowed by long use are still employed.

Les Blessures de l'Abdomen. Par J. Abadie (d'Oran), Correspondent National de la Société de Chirurgie. Avec Préface du Dr. J. L. Faure. Une volume de 240 pages avec 67 figures originales et 4 planches, hors texte. Price, 4 francs. Paris: Masson et Cie., 1916.

This volume is intended to be timely above all. Concerning abdominal wounds there are more differences of opinion than when other localities are involved. We cannot reconcile the results of expectancy with those of operation, because cures are seen under non-operative management. Palliative as well as radical operations have a field. Three objects are always kept in view, viz., the doctrine, or determination of the method of choice for the individual case; the organization, which makes it possible to treat the case properly, and, finally, the technique.

Medical and Surgical Reports of the Episcopal Hospital, Philadelphia. Volume III. Edited by Astley P. C. Ashhurst, M.D. Published through the generosity of a friend of the hospital. Octavo of 356 pages. Philadelphia: Press of William J. Dornan, 1915.

This volume consists of collected papers by members of the attending staff, the papers being based on work done in the Episcopal Hospital during the years 1914-1915. Many of the articles have been published in medical journals and are reprinted so that the hospital shall receive credit for all articles based upon material it has furnished. There are twenty-five contributors who have furnished thirty-eight papers representing work in the following departments: Medical, Surgical, Orthopedic, Ophthalmic, Aural and Laryngeal, Obstetric, Dermatological, and Dental. Many of the papers are profusely illustrated and practically all reflect much credit upon the institution with which their authors are connected.

A Manual of Otology for Students and Practitioners. By Charles Edwin Perkins, M.D., F.A.C.S., Professor of Clinical Otology in New York University and Bellevue Hospital Medical College; Associate Aural Surgeon to St. Luke's Hospital; Associate Aural Surgeon to New York Eye and Ear Infirmary; Fellow of the American Otological Society, New York Otological Society, New York Academy of Medicine, etc. Illustrated with 120 engravings. Price, $3 net. Philadelphia and New York: Lea & Febiger, 1916.

A thorough knowledge of the ear from the anatomical, physiological, and pathological standpoint is notoriously very difficult of attainment. By which is meant that to learn how to properly treat diseases and affections of the ear is by no means easy. It follows then that this branch of medical study is a difficult part of the student's curriculum. The aim of Dr. Perkins's manual is to lighten these difficulties for medical and post-graduate students and to supply data which will enable those who thoroughly master them to become capable aurists. This aim appears to have been accomplished in a satisfactory manner. The chapters of the suppurative diseases of the labyrinth may be especially recommended.

Society Reports.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

Two Hundred and Eighty-first Regular Meeting, Held November 3, 1916.

DR. JOHN S. THACHER, PRESIDENT, IN THE CHAIR.

Rhinoplasty. — Dr. ROBERT ABBE showed a man on whom he had made an unusually presentable nose by a novel plastic operation. The entire nose, except the edges of the nostrils and tip, had been destroyed by cancer, which involved the septum and sides so that they required extensive removal. To make a nose by the usual flap from the forehead would have left a deep saddle-nose defect, so that a central support was required. This Dr. Abbe made by undermining a triangle of skin from each cheek, its base at each side of the nose. The nutrition of these flaps came from the cellular tissue and periosteal base, inasmuch as the skin was cut through superficially clear up to the nasal defect, but deeply on the cheeks. These flaps were turned over the nasal defects so that their points crossed each other and they were stitched together side by side where the bridge was needed. The flaps had their skin side inward and wet side up. On this bridge was now laid a forehead flap wet side down carefully stitched to the tip of the nose and cheeks. Thiersch's skin grafts then covered the forehead defects. In two weeks the redundant skin at the root of the nose was carefully cut out and the shape of the nose was symmetrically balanced. The patient breathed freely through both nostrils on account of the skin lining where the cheek flaps were inverted. Each cheek presented a fine horizontal scar. There was every reason to believe there would be no sagging of the bridge.

Inoperable Peripheral Gangrene. — Dr. W. GILMAN THOMPSON read this paper (see page 1103.)

Dr. G. E. BREWER said that in many cases of peripheral gangrene the general condition was so poor that amputation beyond the probable extent of the gangrene was extremely risky. In many cases small local amputations were imperative whatever the patient's condition and these had to keep pace with the extension of the gangrene. He was greatly interested in the hot-air treatment. He had used the hot air in treating burns, but not in treating gangrene. The relief of pain and the elimination of the odor were strong recommendations for the procedure as outlined by Dr. Thompson.

Dr. WM. H. PARK said that he had had two experiences in gangrene which were interesting. In a case of typhoid fever, two subcutaneous injections of horse serum for the control of intestinal hemorrhage had been followed by gangrene and sloughing of the surrounding connective tissue and the overlying skin. The areas were as large as one's hand but, while serious, did not interfere with the course of the disease. In a case of scarlet fever, gangrene and sloughing had followed a subcutaneous injection of serum. No permanent harm had resulted. Dr. Park was of the opinion that some other elements than pressure entered into the causation of the gangrene in both cases.

Dr. J. A. FORDYCE said that gangrene was not infrequently encountered in syphilitic endarteritis. This gangrene might be very extensive. A confusing point in these cases was that they not infrequently showed a negative Wassermann reaction. It was very unsafe to regard them as nonsyphilitic on this alone. In all such cases a provocative dose of salvarsan should be given. This frequently changed a negative reaction to a positive one and made the diagnosis certain. In all cases of doubt autosyphilitic treatment should be instituted.

Dr. L. A. CONNER said that in cases of gangrene associated with diabetes a determined effort should be made to reduce the patient's blood content of sugar to as nearly normal as possible. Under normal procedures this end could usually be attained with a fair degree of promptness and the cases of gangrene in diabetes which he had seen had been greatly helped. He strongly advised conservative measures in the treatment of these cases and considered medical care more helpful than surgery.

Dr. ROBERT ABBE said that one of the chief advantages of the hot-air treatment of these cases was the purification of the atmosphere. This was a very important feature of the treatment. At times prompt amputation must be insisted upon. He had used spinal anesthenia in these cases with great satisfaction and had obtained quick convalescence. He had seen one case of apparently severe gangrene make a spontaneous recovery. The surface of the great toe had been blue black, but only a shedding of the cuticle had occurred.

Dr. M. ALLEN STARR asked if hot air had been employed in the treatment of Raynaud's disease.

Dr. C. L. DANA said that he had used dry heat for a good many years and had obtained good results with it in Raynaud's disease.

Dr. GILMAN THOMPSON, in reply to a question of Dr. Thacher's, said that the best temperature he regarded as about 150° F. He considered the free circulation of the hot air as most important to produce evaporation. The current of hot air should be fairly strong. Where the employment of hot air had been impracticable he had used 95 per cent. alcohol with satisfactory results, this being far better than the weak solutions usually employed.

Tonsillectomy in Poliomyelitis.—Dr. J. C. ROPER presented this communication. In the recent epidemic of poliomyelitis the New York Hospital had opened a special branch hospital for the treatment of this disease. At this hospital the bacteriology of the disease had been studied by Dr. E. C. Rosenow of the Mayo Clinic, Rochester, Minn. From pus expressed from the tonsils of the patients during life, Dr. Rosenow had isolated a streptococcus which produced paralysis in small animals and monkeys. Tonsils removed at autopsy had revealed small foci of purulent material from which same organism was isolated with the same result. This organism Dr. Rosenow considered identical with that recovered from the spinal cord by Flexner and Noguchi. Many cases of poliomyelitis showed a tendency to progress as regarded paralysis. After the acute symptoms had subsided in these cases, extreme irritability persisted accompanied by a slight fever and apparently at times an extension of the paralysis. In these cases, on the basis of Dr. Rosenow's work, the possibility was assumed that the process was being kept up by reinfection from some source, probably the tonsils. Tonsillectomy was performed in twelve cases and foci were found in many of the tonsils removed. No acute cases were operated upon. In the case showing the most marked improvement, operation had been performed on the 21st day of the disease. The tonsils contained three typical foci. Operation on all of the other cases had been performed from the 23rd to the 35th day of the disease. Several seemed distinctly benefited. Because of the number of deaths occurring after the first week (50 per cent. in this series) if Dr. Rosenow's work was confirmed we would seem justified in cases of delayed recovery in removing the tonsils as possible infecting foci. No untoward results were observed.

Dr. W. H. PARK said he did not feel that much progress had been made during the past six months in the knowledge of the disease. Personally, he could not yet accept the possibility of the process of the disease being kept up by repeated infections from a tonsillar focus. Rather he regarded it as akin to rabies and cerebrospinal meningitis in being a single infection of the central nervous system. There was no question but that Dr. Rosenow was a skilful and enthusiastic worker, but Dr. Park doubted if he had established the identity of the streptococcus isolated from the tonsils with the Flexner and Noguchi organism recovered from the spinal cord. At the Department of Health laboratories, they had gotten the small forms from eighteen of nineteen cases but had seen no transmutations to large forms. It was probable that infection occurred through the intestinal tract as well as through the nasopharynx and tonsils. Possibly something of interest and importance would be developed during the next six months from the work now being carried on at the laboratories of the Department of Health.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Forty-second Annual Meeting, Held at Indianapolis, October 10, 11, and 12, 1916.

THE PRESIDENT, DR. WILLARD J. STONE OF TOLEDO, OHIO, IN THE CHAIR.

(*Concluded from page 1094*)

Operative Treatment of Tuberculous Spine. — Dr. HENRY B. THOMAS of Chicago stated that the Hibbs technique had the following advantages: it copied nature in her preparation for the fixation of the verte-

bræ. It required operation only in the posterior region of the spine itself, making unnecessary the removal of bone from the leg. The technique, though difficult at first, became simple with repetition. It immediately reduced the kyphotic deformity by the length of the spinous process, usually one-half to one inch. Ankylosing the articular processes greatly aided in the fixation. Welding the opposed laminæ was an additional link in the chain of ankylosis. The most important suggestion regarding the after-treatment concerned the mechanical fixation after the patient was kept in bed for six weeks; either a cast or a brace was worn for from six to ten months, with constant observations of the position and progress.

Dr. John Ridlon of Chicago said that in these operations of Hibbs and Albee for the treatment of tuberculosis of the spine, he still used braces. It was claimed that it shortened the duration of the sickness. Perhaps it did, but sometimes it certainly did not, because all these cases were not perfect restorations, despite Albee. Some of the patients died as the result of the operation, some of the grafts came out, some of the grafts broke, and a great many of them that were put in were put into spines already ankylosed through the course of time and by the grace of God. These were the best results that were to be had when a graft was put into a spine that was already perfectly solid. There was no doubt that in selected cases this operation had a place, and he was of the opinion that the Hibbs operation was a little more appealing to one's judgment of what was right than the Albee. On the other hand, he had seen many of these operations, he had assisted in some, he had done none himself, and he never would.

Dr. Charles Davison of Chicago stated that any procedure which would shorten the duration of anything so serious as Potts' disease should be entitled at least to consideration. The probabilities were that the real benefit could only be decided by a large series of cases collected for many years. He had been very much interested in Dr. Thomas' work at the Cook County Hospital, and he had the honor to see some of the cases of Albee, which he did, collected through quite a period of time. The thing that he was most interested in was what happened to the transplant. He made experiments also along other lines and along lines of bone grafting. With a transplant taken from the same individual and opposed to the same kind of bone, for instance a contact of the tibia, to a contact bone of the spine, if it was done in an esthetic manner, if there was absolute immobilization of the transplant, we got a primary union similar to the primary union of one of the soft parts. For the time being at least the transplant left a succulent pabulum between it and the host when it went on and became an integral part of the bony framework. As long as it had function it would remain; when the function ceased it would deteriorate to a certain extent. In the Hibbs method of bony repair it seemed to be different. The bone was taken from the same neighborhood, but instead of being kept in a mass it was largely minced or broken up in particles. Some of the pieces might be intact so that they would heal promptly and become a part, but largely the bone was broken up, the bony cells were liberated, the lining of the bone cell was given up, and we got a new growth of bone there much like a callous. That continued to immobilize as it became osseous as long as there was function; when function ceased it gradually absorbed and went to the compensation between strength and bone.

Dr. John D. Trawick of Louisville said that he had seen Dr. Thomas operate and he must say he was just a little enthusiastic about the method of his operation. He should be very glad if he would discuss the question of the anesthetic for these little patients. Was the risk of the anesthetic the ordinary risk that was to be expected in any capital operation for a child? Was there a choice of anesthetics, and if there were any particular points he could bring out in his closing discussion bearing relatively on the mortality as it pertained to the anesthetic, he should be very glad to have his view.

Dr. W. B. Owen of Louisville thought we made a great mistake in using the word "cured" for these cases. In tuberculosis of the spine, or pulmonary tuberculosis, no matter what area of the body might be involved, we made a mistake to use the word "cured." The first reports were really almost too good to be true. He thought they had proven not to be true; that is, they had not lasted. Two hundred and fifty operations for bone transplant with one hundred per cent. cure was hard to swallow at one time. He had had a good many of these cases and did not feel the operation itself was a serious one. The shock that resulted from it was very slight. In many cases an opiate was not necessary. He did not think it made any difference what anesthetic was used, so long as we were using the best that was known for any surgical procedure. As to the two operations that Dr. Thomas discussed, while he had had very little experience with the Hibbs operation, it seemed to him very simple and in some respects a more feasible procedure, although he should think there would be one objection, and that was the point that was first claimed as a point in its favor—the flexibility of the spine produced by the Hibbs rather than the autogenous splint. If we allowed motion in the spine the cure was not so apt to take place. One splint would probably be retained in place more satisfactorily than several splints, and in the breaking down of the spinous process that was what it meant—it was made up of a number of pieces of bone.

Doctor Thomas, in closing, said that in regard to the anesthetic, he thought Dr. Trawick probably asked the question because he saw a fatal result he had. He had had two deaths on the table. He thought both of them were from the anesthetic, or the way the anesthetic was given. At one of the cases he lost Dr. Trawick was present, and he had made it a rule ever since to attempt to do no operation on the spine unless he had a professional anesthetist. He wanted no intern to give the anesthetic for him when he operated on tuberculous spines. There was no trouble, the children got along nicely, especially if we kept them in the hospital for a few days beforehand and got acquainted with them, so they went to the table without fright. They did nicely so far as the anesthetic went.

Tumors of the Breast.—Dr. J. Garland Sherrill of Louisville considered proper palpation the most valuable of all the means at our command for determining the character of a mammary tumor. If not properly employed, however, it might be worth less. Very little could be learned by pinching the breast between the fingers; the proper plan was to place the palm of the hand flat on the breast and gently press the gland against the chest wall. This would reveal any abnormal mass, show whether it was indurated or not, determine its mobility over the chest wall or pectoral muscle, also its mobility under or attachment to the skin; its outline elasticity, and whether or not it was encapsulated. The observer would also note the amount of pain produced by pressure and manipulation. By gently sliding the breast over the pectoral muscles with the palmar surface of the examining finger its attachment could be readily made out, and dimpling of the skin with slight fixation occurring early in cancer could be detected. Palpation also enabled one to determine the enlargement of the axillary and cervical glands. Recently a case came under his observation where the patient had a malignant tumor of considerable size in the breast, which could scarcely be detected by flat palpation over the breast; but was readily made out by lateral compression. He had also seen a case where there was a malignant growth of supernumerary glandular tissue lying some distance above a normal mammary gland. Certain characteristics were present in benign enlargements whether of cystic or solid type. They occurred at any age, more often in the young. They grew slowly or not at all. They were usually encapsulated and never infiltrated the surrounding tissues; they were mobile, showed no glandular enlargement and were usually painless, but in certain neuralgic patients might be quite painful. They occurred in unmarried and nulliparous women especially. Malignant growths usually developed after thirty, but sometimes as early as eighteen years of age. They were likely to grow slowly but constantly if carcinomatous; fast but spasmodically if sarcomatous. They were encapsulated, with the possible exception of certain cases of sarcoma. They became attached to the skin and fascia quite early. Early glandular involvement was shown in carcinoma. Pain was a late symptom, but always present in the later stages. These growths usually occurred in parous women. An irregular outline and induration gradually merging into surrounding tissue is characteristic of scirrhus. It was not always easy to differentiate between adenoma, adenocystoma, cystoma, and a cysto-sarcoma; and adenocysto-carcinoma of the proliferating type was always difficult to distinguish from the above types.

There was also a border line condition where pathologically the tissue was benign in one portion and malignant in another, seen in cases of chronic cystic mastitis of Koenig. In such cases histological examination at operation was imperative to determine the best line of operative procedure. In rare instances abscess and suppurative cysts of the breast had been mistaken for a malignant growth. In order to verify the clinical diagnosis every mammary tumor should be subjected to microscopic examination.

New Methods of Pyloroplasty for Congenital Pyloric Stenosis.—Dr. ALFRED A. STRAUSS of Chicago drew the following conclusions: "The advantages of pyloroplasty over posterior gastroenterostomy are (1) The incision required is very small, in contradistinction to that necessary in performing posterior gastroenterostomy, large enough to deliver the partially distended stomach, transverse colon, and then to find the right loop of jejunum. (2) Those who have performed gastroenterostomies in these infants will appreciate the saving of a tremendous amount of shock thus secured. (3) The methods of operative procedure described cover every form of pathologic condition so far found in congenital pyloric stenosis. (4) The operations reconstruct a pathologic pylorus to a more normal pylorus, particularly as to its lumen and enormous thickness of musculature. Finally, the normal anatomical relation of the stomach to bowel is preserved by the pylorus remaining the normal connecting tube between stomach and duodenum. The developing liver and pancreas in the infant, which we know from experiments in physiology are stimulated reflexly by food passing through the duodenum, must certainly be considered in a more normal condition here than with a closed-off pylorus, as occurs after a posterior gastroenterostomy. Moreover the duration of the operation is one-third the time taken by posterior gastroenterostomy. The most important fact regarding this operative procedure is that these children come back from the operating room with no more shock than from the smallest minor operation. The projectile vomiting has ceased, no peristaltic waves are seen. they take their nourishment, and do not appear ill at all, as one would expect from an abdominal operation."

Surgical Treatment of Internal Hemorrhoids Under Local Anesthesia.—Dr. LOUIS J. HIRSCHMAN of Detroit stated that the technic was very simple and was efficacious for the following reasons: "(1) The anesthesia was complete and satisfactory. (2) There was no necessity of damaging the sphincter by dilating or divulsing it by mechanical means. (3) By the everting forceps the use of specula which only obstructed the view was obviated. (4) The method of placing the ligature at the junction of pile and healthy mucosa by shutting off the blood supply from the branches of the superior hemorrhoidal vessels rendered the operation almost bloodless. The only hemorrhage with which one met came from the power portion of the wound which was largely supplied by the inferior hemorrhoidal vessels and was of no consequence. (5) By tying the ligature with a long and short end the long end of the ligature was used as a suture and when tied to the short end and at the top of the wound brought the edges together so that good hemostasis was assured. (6) By excising the hemorrhoid and removing all diseased tissue below the mucosa level and down to the sphincter all of the pathology was eradicated and recurrence was impossible. The clamp-and-cautery or clamp-and-suture operations were so often followed by recurrence because only the top of the hemorrhoid was removed. All under the bits of the clamp was left behind and that very often was the major part of the hemorrhoid. By the open operation and the excision, nothing could be left behind and all of the hemorrhoid was accounted for. If the average surgeon who used a clamp would before he sewed or seared remove the clamp, opening the wound, thus discovering what he left behind, the author was sure there would be no more clamp operations performed for the removal of hemorrhoids. (7) Postoperative anesthesia was so satisfactory when quinine and urea were employed that the patient was able to be up and around after the first day or two, and many of them refused to stay in bed at all. (8) The lateral position prevented any sacroiliac strain which was often caused by the lithotomy position."

Fat as a Hemostatic in Renal and Prostatic Surgery.—Dr. IRVIN S. KOLL of Chicago said that the clinical experience at this time was sufficiently extensive to warrant the conclusion that the method could be considered of practical value. The fat was preferably obtained from a dog, under strict aseptic precautions. Placed in an airtight, sterile container, in salt solution, on ice, it could be kept indefinitely. Should it not be possible to obtain it from a dog, the fat could be taken from the patient at the time of operation. There was usually sufficient perirenal fat for the kidney work, but the patients were often not sufficiently adipose to obtain enough fat from the site of the incision in suprapubic prostatectomy. Following the enucleation of the prostate, the bleeding was checked either by hot water irrigation or tamponing the cavity tightly for a few moments with gauze. The cavity was then well fitted with fat, and several interrupted catgut sutures were tied over the edges of the cut mucous membrane of the bladder to hold the fat in place; enough of an opening was left for drainage. The fat would slough out in two or three days after it had served the purpose for which it was intended. The efficiency of this method of hemostasis was indicated by the cessation of the oozing, as noted by the rapid clearing of the urine. When doing a pyelotomy, two sutures were placed longitudinally at either side of the pelvis before it was incised. After removal of the calculus and exploration by the finger, a piece of fat—preferably perirenal—was placed over the incision and the opposite ends of the two sutures were tied over the fat. This made a perfect closure and required no further suturing. Should it be necessary to cut into the cortex of the kidney for the removal of the stone—the cavity thus left was plugged with a piece of fat, another piece was placed over the incision, the sutures were then run through this plug and tied over the other piece. Lacerations were repaired by using a large piece of fat and including it in the suture. This prevented tearing through the kidney at the same time it held the fat in place. The rapid clearing of the urine and recovery of 19 suprapubic prostatectomies, together with the satisfactory use of the above method in 20 kidney operations, the writer felt, should place the use of fat as a hemostatic in renal and prostatic surgery upon a sound surgical basis.

Tumors of the Kidney and Stone.—Drs. H. H. MARTIN and H. O. MERTZ of LaPorte, Ind., from their studies, concluded: "(1) Epithelial tumors of the kidney are most frequently associated with renal calculi. That of these, the relative proportion of association is greater in epithelial tumors of the kidney pelvis. (2) Cystic tumors, associated with renal stone are next in frequency. (3) The coexistence of renal calculi and mesotheliomatous and sarcomatous tumors is rare. (4) There does exist a definite and constant relation between the stone and epithelial tumors of the same kidney. The stone in the majority of cases, fifty-six per cent. in epithelial tumors of the parenchyma and sixty-two per cent. in epithelial tumors of the pelvis and ureter, being the primary lesion, "which because of its irritation, direct and consequent, is the principal etiological factor in the production of the neoplasm." (5) In cystic tumors of the kidney, in the true polycystic degeneration the calculus is invariably secondary, or but chance, while in a large cyst it not infrequently is one of the etiological factors. (6) In mesotheliomatous tumors the stone is always secondary, or but chance occurrence, while of the sarcomatous neoplasms we have collected two cases with an uncertain relationship existing, while in the third case the stone was secondary. (7) That in the coexistence of stone and neoplasm in the kidney of a child must be extremely rare. In our searches we have found no such association."

High-Frequency Electricity in Treatment of Uterine Fibroids and of Prostatic Enlargements.—Dr. NATHAN ROSEWATER of Cleveland summarized as follows: "(1) High frequency currents applied through glass vacuum electrodes upon the mucosa of the vagina and rectum are not painful, irritating, nor seemingly harmful in moderate doses over long periods of time. (2) High frequency currents given as described do not tend to cause sterility, but on the contrary several cases of pregnancy occurred after treatment in married women who had been sterile over periods of eight to eleven years. (3) In cases of acute specific prostatitis, immediate cessation of painful symptoms and rapid cure without recurrence, occurred in the cases treated. (4) In the cases of enlarged prostate of the senile, without inflammatory conditions a slower but equally posi-

tive improvement was observed. The first noticeable passage of urine—after two years absolute cessation except with catheter—was after one month's treatment, bi-weekly, and the next six weeks later, followed by others soon after. (5) In cases of even extremely large uterine fibroids an extra prolonged treatment weekly, or even once a month was followed by decided reduction in size and in restitution to normal function. It is uncertain how many treatments should be given, over what period of time they should be repeated; but most of those who stopped treatment subsequently submitted to operation; none died subsequently of malignancy. (6) Case 6 was not given iodides, ergot or other medication nor was she bandaged, yet her fibroid was materially reduced in size, and normal function returned, so that the high frequency current stands credited with mass reduction and uterine tonicity. In case 5, function was improved long before mass reduction was noticeable and leaves it uncertain as to what aid was given by the bandage, the iodides or the ergot, singly or combined with the electricity. The reverse is also true; the use of the bandage in appropriate cases, together with the iodides and ergot, is not incompatible with a successful result in the treatment of uterine fibroids. (7) High frequency electricity applied in the rectum and vagina for tuberculous peritonitis is not incompatible with a successful recovery after laparotomy, reserving laparotomy for those cases that show no improvement without it."

Value of the Cystoscope in the Differential Diagnosis of Abdominal Lesions.—Dr. COURTNEY W. SHROPSHIRE of Birmingham, Ala., stated that the very best results in the differential diagnosis of abdominal lesions were obtained by the combined efforts of the surgeon, cystoscopist, Roentgenologist, and laboratory technician. It was impossible in a great many cases to say without the aid of the cystoscope whether an existing lesion was within the abdominal cavity or represented some pathological condition of the urinary tract. It was therefore his belief that a cystoscopic and radiographic examination should be made in every case which bordered on uncertainty. For it was only in this way that we would avoid serious errors in diagnosis and increased risk to our patients. Chute of Boston reported some time ago a case of renal calculus causing marked intestinal symptoms, referable to the splenic flexure of the colon. The patient was advised that laparotomy was necessary, but for some trivial reason refused operation. During a similar attack some time later an examination of the urine revealed the presence of pus and blood. These findings were followed by a cystoscopic and Roentgenographic examination. A large calculus was discovered in the left kidney. Following an operation relief was immediate, and the patient had had no further symptoms. The fact which impressed him more than any other in this instance was the failure to make a cystoscopic examination in this very obscure condition—for neither the symptoms nor the radiographic examination of the intestinal tract was of great value—and it was not uncommon for lesions of the left kidney to produce symptoms simulating obstruction at the splenic flexure of the colon. Symptoms somewhat similar to the above occurred in a patient whom he saw in consultation at one of the local infirmaries. There was intense abdominal pain, which was general, accompanied by marked tenderness to pressure along the lower border of the ribs on the left side. The patient's bowels had not moved since the beginning of the attack, three days previous, and there was intermittent vomiting, a distended abdomen, and a temperature of 102°. After considerable effort on the part of the surgeon the patient's bowels moved. Examination of the feces for blood was negative, and nothing of value could be learned by means of radiographic examination. After the bowels had been emptied he was very comfortable and remained so for several days. His pain then returned, and the original symptoms again developed. At this time we were called to make an examination of the urinary tract. A cystoscope was easily introduced, bladder negative, right ureteral opening negative, left ureteral opening very much congested. Catheter passed to right pelvis with difficulty, left catheter was introduced, meeting with some resistance about 5 c. above ureteral opening, but it was gradually forced higher by gentle manipulation. Urine dripped from left ureter continuously and rapidly until 150 c.c. were collected. Functional test with phthalein as follows: Right, appearance 3 minutes; 30 minutes 48 per cent.; left, appearance, 10, 30, 10 per cent. Thorium was injected into the left pelvis and the radiographic examination showed a large irregular shadow extending from the kidney region downward to the brim of the pelvis. Diagnosis, hydronephrosis on left kidney. The surgeon who operated on this patient made an incision anteriorly, removing the left kidney with great difficulty. On examination, we found a large hydronephrotic kidney, the kidney substance proper being reduced to a mere shell. This sac was filled with a gelatinous substance. The patient died on the third day following operation. No autopsy was held. In concluding his paper he said that: (1) Too much reliance should not be placed upon pain or even tenderness to pressure in vague abdominal lesions. (2) Lesions of the left kidney often produced symptoms referable to the intestinal tract. (3) Renal colic was caused by an overdistention of the renal pelvis, and that an obstruction in the lower third would often cause symptoms referable to the kidney region. (4) A cystoscopic and radiographic examination were an absolute necessity in the differential diagnosis of abdominal lesions.

Treatment of Fractures of the Long Bones.—Dr. F. P. CORRIGAN of Cleveland said that reduction under anesthesia should be the procedure unless strongly contraindicated by age or infirmity. Immobilization, using immobilization only in the sense of maintenance of reduction. Complete immobilization with splints was not possible nor was it necessary; if reduction was maintained slight motion between the fragments did no harm, and it was even held, by some authorities, that it was in a sense physiologic and an important factor in stimulating osteogenesis. The form of immobilization apparatus was not important, but there was a very decided trend toward the made-to-measure splint, of plaster Paris, silicate of soda, etc., rather than the ready-made splints turned out by the manufacturers to fit all fancies. The principle of extension and early reduction were the ones upon which he wishes especially to lay stress because extension had never been given the attention in this country that it deserved. The work of Bardenhauer of Cologne, which was well known and largely accepted, in Europe, had been very little mentioned in this country, and it was his belief that the greatest advance in fracture treatment would come from a wider study of the principles of extension laid down by him. In order to facilitate the early application of extending force to the limb, he had devised an extension bandage or sleeve woven in such a fashion that when pulled upon from below it became smaller and gripped the limb. The advantage of this extension bandage was primarily that it did away with the disagreeable and annoying features of adhesive plaster. Moreover, it was easily and quickly applied, easily removed and was sterilizable.

Technique of Nephrectomy for Renal Tuberculosis and Other Infections of the Kidney.—Dr. PAUL MONROE PILCHER of Brooklyn, N. Y., said that, leaving out many of the points upon which most surgeons agreed, such as a sufficiently large incision to expose the kidney region, resection of the ribs, if necessary, and removal of much of the perinephritic fat, he wished to direct attention to three points: (1) The adhesions of the kidney to the surrounding tissues. (2) The treatment of the pedicle. (3) The treatment of the ureter

1. In studying the specimens which he had removed, it had been repeatedly noted that at those points where the active tubercular lesions came to the surface of the kidney, the surrounding tissue always threw out a defensive line of plastic material forming adhesions covering this point. This was especially true at the upper pole of the kidney. He respected these protective barriers thrown out by nature by carefully ligating the adhesions and cutting the adhesions between ligatures leaving a considerable portion attached to the kidney itself. As soon as the capsule beneath the point of attachment of these adhesions was lifted up active tuberculous foci were almost invariably discovered. It was his contention, then, that the stripping up of these adhesions in removing the kidney was a source of danger, for if the kidney surface be left unprotected during the manipulation of nephrectomy it was very easy for caseous material to be squeezed into the wound, and infection take place. He had found it of advantage as a rule to attack the upper pole, for it was here the adhesions were strongest, and while it took some time to tie and cut these adhesions, still the result was a freely movable upper pole which allowed us more quickly to approach the vessels which were in the superior half of the pedicle.

2. If the upper pole had been freed it was usually possible to pass the finger down beneath the pedicle and by careful dissection to expose the elements of the pedicle. There was very little danger of rupturing the pedicle if too much strain had not been put upon it. By a certain blunt dissection and the use of gauze the fat which made up the chief bulk of the tuberculous pedicle could be stripped down and the artery usually became plainly evident. Then in most cases the ureter was found and easily differentiated. Having controlled the pedicle by the finger beneath it to hold it up, a ligature carrier was passed between the vessels and the ureter, and a chronic gut ligature was applied to the vessels before they were cut. Then a second ligature was applied to the vessels near the kidney itself, a clamp applied near the ligature which controlled the vessels and the vessels were then divided. Before doing further, a second ligature was placed around the vessels and, if possible, the artery and the vein were also tied separately. It was needless to say that this was not always possible. Having freed the kidney from its restraining vessels it was lifted up, and it was very simple then to strip the tissues away from the ureter for a very considerable distance, usually allowing us to control 4 or 5 inches of the ureter without much difficulty. Up to this point it would be noted that the wound had been entirely protected from infection, first by not disturbing the adhesions protecting the active tuberculosis near the surface, and, second, by not having exposed anything which communicated with the pelvis of the kidney or the interior of the ureter. He then allowed the kidney with its ureter still attached to hang out from the lower end of the wound and proceeded to close the wound from which the kidney had been removed, draining together all of the deeper tissues and bringing together the fascia and the muscles in their proper relations and entirely closing the wound, suturing the skin, leaving the kidney still attached by its ureter coming out at the lower angle of the wound.

3. The final step: Suture was passed through the skin just above the ureter, and this was used as a ligature to tie off the ureter. Then the needle of a hypodermic syringe containing 95 per cent. phenol was inserted into the upper portion of the ureter and 10 to 15 drops of phenol was injected into the ureter. Then the upper portion of the ureter was clamped and was cut between ligature and clamp. The stump was cauterized and dry dressings applied. His experience since he had employed this technique had been more uniformly satisfactory than it had been with any other method.

Roentgen Examination of Fractured Skulls.—Dr. WILLIAM H. STEWART of New York City said that the frequency with which fracture of the skull was mistaken for various other conditions, especially in cases of coma, called for any method which would make a rapid and positive diagnosis. This, with many other difficulties which were encountered in the correct interpretation of this lesion, rendered the routine Roentgen examination of the skull of the greatest importance in all head injuries. It offered an actual visual demonstration of the presence or absence of fracture, its location, character and extent. It was a noteworthy fact that each succeeding collection of statistics of the relative frequency of fractures gave this lesion an increasing percentage; thus Guilt gave 1.45 per cent., von Bruns 3.4 per cent., and Chudosky 3.8 per cent. These figures, he believed, in view of the more accurate diagnosis with the Roentgen ray, were altogether too low. If a systematic Roentgenographic examination were properly made of all injuries, either direct or indirect, of the head, he felt confident that the relative frequency of fractures of the skull would show a much larger percentage. He based this statement on the number of cases in which the diagnosis could only be made by means of the Roentgen examination, especially when the patient had no symptoms, either objective or subjective, only a history of a fall. In one of the institutions he was connected with 250 cases of head injuries had been examined since Jan. 1, 1915, forty-five of which were positive for fractures—about 20 per cent. Patients were often in a comatose or irritable condition when referred to the Roentgenologist; therefore, extreme patience and perseverance were required. It must be borne in mind that the minimum amount of disturbance and movement was the rule. In the examination of these cases the head must be absolutely fixed and all respiratory movement overcome. If the objective symptoms, such as bleeding from the ear, nose, or mouth, laceration of the scalp, hematoma, or paralysis were present, they were a clue as to the possible site of the fracture, and attention was naturally directed toward that area. This must not mislead one, however, for every examination should cover the frontal, both parieto-temporals, occipital and basilar regions. Having obtained satisfactory Roentgenograms, it was necessary for us to have the experience and anatomical knowledge to make the correct interpretation. In the reading of Roentgenograms of the base of the skull, beginning behind, we saw the foramen magnum and within the odontoid process of the axis. Just forward from this opening on either side the mastoids were distinctly reproduced with the associated shadows of the petrous portion of the temporal bones. Anterior to this was a clear view of the middle fossa. If we had not produced too much extension of the chin the anterior fossa could be seen well in front of the overlying shadow of the lower jaw. Fractures of the zygomatic arch with the amount of displacement were usually beautifully shown in these base plates. In the interpretation of the frontal, lateral and occipital regions we had to remember the normal radiating lines cast by the grooves on the inner table of the skull which accommodated the meningeal blood vessels. These grooves spread out fan-shaped from an anterior point backward. The shadows cast by the diploic spaces, between the inner and outer tables of the skull, were lines extending vertically upward from a point at the base, directly in variance to the shadows representing the meningeal grooves. Fractures usually showed as light, sharply cut lines of varying width, depending upon the amount of separation; they might be vertical, horizontal, or curved, but were seldom directed in the same manner as the blood vessel grooves.

Roentgen Studies in Bone Pathology with Special Reference to Spontaneous Fractures.—Dr. LEON T. LE WALD of New York City, stated that in two cases the spontaneous fracture occurred in the femur, one in the middle of the shaft and in the other at the junction of the shaft with the neck. In neither case could complete reduction be accomplished, but as the final outcome proved, this appeared to be a desirable rather than an unfortunate outcome, as the general alignment was better than the corresponding bone on the other side in each instance. This would almost make it appear as if the spontaneous fracture were an attempt on the part of nature to straighten the extreme deformity which one saw in these cases. Rapid and complete union of the fragment occurred in both cases. In his series of pathological fractures, bone cyst merited most careful consideration, for without careful Roentgen examination an ordinary fracture would have been diagnosed, and inadequate treatment would have been instituted. In two cases a perfect result was obtained, in one by open operation and curettage, in the other a similar procedure supplemented by a bone graft. A rare form of bone cyst was encountered in the skull of a young woman. This was successfully dealt with by removal. Without Roentgen examination, which showed the absolute limitation of the process, sarcoma would have been thought of, and either no operation or a very extensive one might have been the method of treatment. In the past, without doubt, many cases of bone cysts had been dealt with too radically even by amputation of an extremity under the supposition that one was dealing with a sarcoma. Spontaneous fracture might give the first clue to a primary or secondary new growth in bone. Roentgen examination of the part involved might immediately establish the diagnosis. Clinical examination based upon the Roentgen findings might then locate a primary growth at some remote part of the body, such as the kidney or prostate gland. Syphilis of the bones might not be suspected until a spontaneous fracture followed by Roentgen examination and a Wassermann test established the diagnosis and pointed the way to a cure, not only of the bone condition but of other unsuspected syphilitic lesions.

Radiation Treatment of Cancer of the Cervix.—Flatau removes the mass with scissors and curette until no cancer tissue remains. Radium is used at the operation surface, while with the *x*-rays an attempt is made to head off metastases by raying all lymphatic areas. The entire pelvis is next irradiated. Recently (1913-1916) eight out of nineteen inoperable cases have been improved or arrested. Of six recurrences, two have shown improvement or cure. Of twenty-four beginning cases, twelve have been cured and seven improved. Of the forty-nine cases treated, twenty are dead and in fourteen the disease is arrested (provisional cure).—*Zentralblatt für Gynäkologie.*

Miscellany.

Mortality Statistics for 1915.—A preliminary announcement with reference to mortality in 1915, issued by the Bureau of the Census, shows that nearly one-third of the 909,155 deaths reported for that year in the "registration area," which contained approximately 67 per cent. of the population of the entire United States, were due to three causes—heart diseases, tuberculosis, and pneumonia—and nearly two-thirds to twelve causes—the three just named and Bright's disease and nephritis, cancer, apoplexy, diarrhea and enteritis, arterial diseases, diabetes, influenza, diphtheria, and typhoid fever. The deaths from heart disease numbered 105,200, or 156.2 per 100,000 of population; this is a marked increase as compared with 1900, when the death rate was only 123.1 per 100,000. The increase has not been continuous, but has fluctuated from year to year. Tuberculosis in its various forms claimed 98,194 victims in 1915, of whom 85,993 died of tuberculosis of the lungs. The decline in the death rate from this disease has been continuous from year to year since 1904 and has amounted to over 25 per cent., from 200.7 per 100,000 in 1904, to 145.8 in 1915. Tuberculosis in all its forms, however, still causes more deaths annually than any other form of bodily illness except heart disease, and about 46 per cent. more than all external causes— accidents, homicides, and suicides—combined. Pneumonia, including bronchopneumonia, caused 89,326 deaths, or 132.7 per 100,000. This rate, although lower than for most of the years from 1900 to 1911, is higher than for 1912, 1913, and 1914. The rate for 1914, 127 per 100,000, is the lowest on record. The death rate from pneumonia, like that from tuberculosis, has shown a marked decline since 1900, when it was 180.5 per 100,000. The fluctuations in the rate from year to year have, however, been continuous. The only other death rate higher than 100 per 100,000 during 1915 was that for Bright's disease and nephritis, 104.7, the total number of deaths due to these maladies being 64,480 and 6,020, respectively. The mortality rate from these two causes increased from 89 per 100,000 in 1900 to 103.4 in 1905, fluctuated more or less between 1905 and 1912, and has shown little change since that time. Next as a cause of mortality come cancer and other malignant tumors, which caused 54,584 deaths in 1915. The death rate from cancer has risen from 63 per 100,000 in 1900 to 81.1 in 1915, and the increase has been almost continuous. It is quite possible, however, that at least a part of this increase is due to more correct diagnoses and greater care in making reports. Of the deaths from this cause in 1915, nearly 39 per cent., 21,221, were due to cancer of the stomach and liver. Apoplexy caused 53,397 deaths, or 79.3 per 100,000 Diarrhea and enteritis caused 48,325 deaths or 71.7 per 100,000; this rate has declined almost steadily since 1900 when it was 133.2. Arterial diseases caused 15,685 deaths, or 23.3 per 100,000; diabetes, 11,775 deaths, or 17.5 per 100,000; and influenza, 10,768 deaths, or 16 per 100,000. The rate for diabetes has risen almost continuously since 1900, when it was 9.7 per 100,000. Of the lesser causes of death, the rate for diphtheria and croup was 15.7 per 100,000, for typhoid fever, 12.4 per 100,000, for whooping cough, measles, and scarlet fever, 8.1, 5.4, and 3.6 respectively.

That the "safety first" campaign has borne good fruit is shown by the figures for accidental deaths. For 1913, 54,011 deaths were reported as due to accident; for 1914 the number was reduced to 51,770, and for 1915 to 51,406; and during this period there was not only an increase in population of the registration area but an increase in the area itself. The rate, therefore, fell from 85.3 in 1913, to 78.5 in 1914, and to 76.3 in 1915. The number of suicides reported during the year was 11,216, or 16.7 per 100,000; the suicide rate has varied but little during the past ten years.

Books Received.

The MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will promptly be made of their receipt under this heading; but this is with the distinct understanding that it is under no obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

LES BLESSURES DE L'ABDOMEN. Par J. ABADIE (d'Oran). Préface de J. L. FAURE. Avec 69 figures dans le texte et 4 planches hors texte. Published by Masson et Cie., Saint-Germain, Paris. 238 Pages. Prix, 4 fr.

NERVOUS AND MENTAL DISEASE MONOGRAPH SERIES No. 7. THREE CONTRIBUTIONS TO THE THEORY OF SEX. By Prof. SIGMUND FREUD, LL.D., Vienna. Authorized Translation by A. A. BRILL, Ph.B., M.D. With Introduction by JAMES J. PUTNAM, M.D. Published by Nervous and Mental Disease Publishing Co., New York, 1916. Second Revised and Enlarged Edition. 117 pages. Price, $2.00.

LES SÉQUELLES OSTÉO-ARTICULAIRES DES PLAIES DE GUERRE. Par A. BROCA. Avec 112 figures dans le texte. Published by Masson et Cie, Saint-Germain, Paris, 1916. 177 pages. Prix, 4 fr.

RADIODIAGNOSTIC DES AFFECTIONS PLEURO-PULMONAIRES. Par F. BARJON. Avec figures dans le texte et 26 planches hors texte. Published by Masson et Cie., Éditeurs, 120 Boulevard Saint-Germain, Paris, 1916. 182 pages. Prix, 6 fr.

BEITRÄGE ZUR KLINIK DER INFECTIONSKRANKHEITEN UND ZUR IMMUNITÄTSFORSCHUNG (mit Ausschluss der Tuberkulose). Herausgegeben von Prof. Dr. L. BRAUER. Redaktion: Für die Originale: Prof. Dr. H. Schottmüller (Klinischer und bakteriologischer Teil) and Prof. Dr. H. MUCH (Immunitätswissenschaftlicher Teil). Für die Ergebnisse: Prof. Dr. H. LÜDKE, in Würzburg. V. Band, Heft 1. Verlag von Curt Kabitzsch, Egl. Universitäts-Verlagsbuchhändler, 1916. 234 pages. Illustrated. Price, 12 marks.

MANUAL OF CHEMISTRY—A Guide to Lectures and Laboratory Work for Beginners in Chemistry. A Text-Book Specially Adapted for Students of Medicine, Pharmacy and Dentistry. By W. SIMON, PH.D., M.D. Published by Lea & Febiger, Philadelphia and New York, 1916. Eleventh edition, thoroughly revised, with fifty-five illustrations, one colored spectra plate and six colored plates, representing forty-eight chemical reactions. Price, $3.50 net.

CONSTIPATION, OBSTIPATION, AND INTESTINAL STASIS (Auto-Intoxication). By SAMUEL GOODWIN GANT, M.D., LL.D. Published by W. B. Saunders Co., Philadelphia and London, 1916. Second edition, enlarged, with 259 illustrations. 584 pages. Price, $7.50 net.

BLOOD-PRESSURE FROM THE CLINICAL STANDPOINT. By FRANCIS ASHLEY FAUGHT, M.D. Published by W. B. Saunders Co., Philadelphia and London, 1916. Second edition, thoroughly revised. Illustrated. 478 pages. Price, $3.25 net.

PERSONAL HEALTH—A Doctor Book for Discriminating People. By WILLIAM BRADY, M.D., Elmira, New York. Published by W. B. Saunders Co., Philadelphia and London, 1916. 407 pages. Price, $1.50 net.

THE OPERATING ROOM—A Primer for Pupil Nurses. By AMY ARMOUR SMITH, R.N. Published by W. B. Saunders Co, 1916. 295 pages. Price, $1.50 net.

SENSITIZED TYPHOID BACTERIA. (TYPHOID SERO-BACTERINS.)

BY A. L. GARBAT, M.D.,

NEW YORK.

ASSISTANT PATHOLOGIST AND ADJUNCT VISITING PHYSICIAN, GERMAN HOSPITAL.

SENSITIZATION of antigens is becoming a recognized important procedure. Sensitization means the mixing of an antigen (bacteria, red-blood cells, proteins, etc.) with its specific antibodies. These antibodies are supplied by the serum of an animal that has been previously immunized with the particular antigen. If, for example, a rabbit or goat receives injections of typhoid bacteria, the usual antibodies (agglutinins, bacteriolysins, bacteriotropins (opsonins), complement fixation bodies, etc.) appear in its serum. If an emulsion of typhoid bacilli be mixed with this immune serum, the bacteria become sensitized; that is, during the process of sensitization the bacteria unite with the specific immune bodies present in the serum.

Several important general rules pertaining to sensitization must be mentioned right here. (1) It is not sufficient merely to mix the bacteria and the corresponding immune serum; it is essential that the bacteria and their antibodies unite, before we can say that they have become sensitized. Thus it is important, primarily, to have an excess of immune serum and, secondarily, to expose the bacteria to the action of the immune serum for a sufficient length of time in order to obtain complete and thorough union. Otherwise incomplete sensitization occurs which manifests itself on animal injection by a production of antibodies stimulated by those bacteria which had remained unsensitized. (2) The immune serum used for sensitizing the bacteria should be free from complement. This is accomplished by heating the serum, if fresh, for half an hour at 56° C. before adding it to the emulsion of the bacteria, or if the serum has been kept for a long period, the complement will have been destroyed. (3) The immune serum may be obtained from an animal of the same or different species, *e. g.* the typhoid bacteria may have been isolated from the human being and the immune serum for sensitization obtained from a convalescent typhoid individual. As a general rule, such a procedure is not practicable; so that the serum for sensitizing is usually obtained from an animal (goat or horse or rabbit) that has been immunized by successively increasing quantities of the respective bacteria, in this way obtaining a strongly immune serum. (4) Finally, sensitized bacilli may be dead or living, depending on whether the bacteria have or have not been killed previous to being mixed with the immune serum.

Results of Injection of Sensitized Bacteria.—Let us first take up animal experiments and see what happens after injections of sensitized bacteria (Garbat and Meyer).[1] It is of interest to compare these findings with those obtained by immunization with the same dosage of non-sensitized bacteria. A description of an actual experiment in rabbits will contrast these clearly. Virulent strains of typhoid bacteria are grown upon agar for 24 hours at 37° C. The growth thus obtained is washed off and suspended in normal saline. The bacteria are killed by exposing the emulsion to 60° C. in a water bath on two successive days. The entire amount is divided equally. One-half is mixed with an excess of a highly immune, inactive typhoid serum obtained from a horse; the mixture is allowed to sensitize in the incubator at 37° C. for 24 hours, then washed carefully in saline, suspended in saline, and injected intravenously. The other half is simply washed the same way, suspended in an equal amount of saline, and also injected intravenously. Certain differences in the two animals are evident:

A. Temperature.—The temperature of the sensitized rabbit begins to rise about one hour after the injection and rises 2 or 3° above the normal temperature. The maximum degree is reached in about 4 to 6 hours. The fever does not remain high, but falls rapidly in 2 to 4 hours. This quick response to sensitized bacteria was recently proven also by Schottstaedt.[2] The temperature of the non-sensitized rabbits rises slowly; it does not, however, reach the same height as did the rabbit injected with non-sensitized bacteria. It returns to normal only after 24 to 36 hours.

This difference in the temperature is observed regularly, and not only after the first, but also after all subsequent injections. As will be seen later on, it is dependent upon the rapid destruction of the sensitized bacilli. This phenomenon proves to us an important characteristic of sensitized bacteria, *i. e.*, that their action is rapid, almost immediate, and of quick response. Any immunity that their action may produce is necessarily more quickly attained.

B. The General Condition of the Animals.—When the maximum temperature has been reached, the sensitized rabbits are much more active and sprightly than the non-sensitized animals, which seem greatly depressed and show signs of serious illness; they sit still and often have diarrhea. They remain in this condition for about 36 hours, while the sensitized rabbits are completely restored to activity after 8 or 10 hours.

When the rabbits received repeated injections at intervals of 8 days and at each time the dose of the antigen was doubled, the non-sensitized rabbits died almost without exception after the third injection. Their temperature dropped far below normal; severe diarrhea continued until death. Post mortem examination showed merely a severe inflammation of the small intestine. This result confirms the con-

clusions arrived at by Kraus and Stenitzer, regarding bacterial anaphylaxis. The sensitized rabbits, on the other hand, reacted more favorably to the third injection, so that it would seem that sensitization reduces the danger of anaphylaxis. The recent work of Jobling supports this finding. Of 7 non-sensitized animals 6 died. Of 7 sensitized animals 2 died.

The above description of the reaction from the injection elicits a second important point in favor of the sensitized bacteria, namely, the *slighter disturbance after inoculation.*

C. Antibody Content of Serum.—The typhoid antibodies are agglutinins, precipitins, complement fixation bodies, bacteriolysins, and bacteriotropins or opsonins. After one or two injections of *sensitized* typhoid bacteria, rabbits do not develop any agglutinins or complement fixation bodies. On the other hand, the rabbits immunized with non-sensitized bacteria get up a high power of agglutination and complement fixation. After a third and subsequent injection of sensitized bacteria some agglutinins and complement fixatives appear, but far fewer in number than in the sera from rabbits immunized with non-sensitized bacteria.

That no agglutinins were produced by the injection of the sensitized bacteria, was by some attributed to the possible development of antiagglutinins, but this is disproven by mixing the non-agglutinating serum in equal parts with a strongly agglutinating one and finding that the power of agglutination is not decreased any more than can be accounted for by the dilution. The absence of agglutinins or complement fixation bodies is very well explained in the light of Ehrlich's theory of saturation of the antigen with its antibodies. The classical experiments of Neisser and Lubowski[3] showed that killed agglutinated typhoid bacilli produced no antibodies. The fact that some degree of agglutination appears after the third or subsequent injection of sensitized bacteria may be due either to the difficulty of complete saturation of such large quantities of bacteria or to a separation between the agglutinin and its bacillus in the blood stream, setting some of the bacilli free and unsensitized and thus capable of stimulating agglutinins. This is hardly ever the case after the first or second injection, if the bacteria have been properly sensitized.

The question that next arises is: Do rabbits that have been immunized with sensitized bacteria, and that have developed no agglutinins or complement fixation bodies, possess any typhoid antibodies at all? Most emphatically, yes. The serum from these rabbits, when examined by Neufeld's method of phagocytosis in the test tube, or Pfeiffer's method in the peritoneal cavity of the guinea pig, shows a very high degree of opsonic or bacteriotropic activity. The examination of the peritoneal exudate shows marked phagocytosis. On the other hand, similar experiments undertaken with the serum from rabbits that had been immunized with non-sensitized bacteria, show a much lesser opsonic activity in vitro and a strong bacteriolytic (*not phagocytic*) action in the peritoneal cavity of mice and guinea pigs. Furthermore, and even more important, is the fact that the serum from rabbits immunized with sensitized bacteria, and containing no agglutinin or complement fixation bodies, is capable of saving mice that had been injected with lethal doses of live typhoid bacteria. This curative property was either entirely absent, or present to a much lesser degree, in the sera of rabbits injected with non-sensitized bacteria. Thus, in summarizing this question of immune bodies, it may be said that injections of sensitized bacteria produce hardly any agglutinins, precipitins, or complement fixation bodies, a moderate number of bacteriolysins, but large numbers of bacteriotropins and curative bodies for mice; while unsensitized bacteria produce large numbers of agglutinins, precipitins, complement fixation bodies, and bacteriolysins, but few bacteriotropins and curative bodies for mice.

In studying the literature on this subject, I have found that some observers, Nègre,[4] Ardin Delteil, Nègre et Raynaud,[5] report some degree of agglutination after the injection of sensitized typhoid bacteria, although only about one-tenth as strong as after non-sensitized. More recently, Lieberman and Acél[6] found identically the same titer of agglutinin and bacteriolysin in rabbits after injection of sensitized as of non-sensitized bacteria. They do not, however, state their method of sensitization, so that I am almost convinced that their procedure was faulty. On the other hand, Pfeiffer and Friedberger[7] corroborated my results. They found *no* precipitation action, an agglutination action of only 1:20, and an especially low bacteriolytic action after injection of sensitized typhoid and cholera bacteria. Their conclusion, however, is erroneous when they say that sensitized typhoid bacteria had no antigenic value; they omitted to test the opsonic value of the serum or its action in animals.

A recent article by Schottstaedt[8] also shows low agglutinating and bactericidal power of the serum in rabbits after injection of sensitized typhoid bacteria. It is wrong to conclude therefrom, as this author does, that "the height of the immunity curve after sensitized vaccines is only about one-quarter as potent, or that sensitized vaccines are less potent than non-sensitized typhoid vaccines." From merely agglutination or bactericidal action, such comparison is not permissible. Bacteriotropic or opsonic experiments in vivo and in vitro, or curative action in animals, will refute such statement. High agglutination or bactericidal action should not be *expected* after injections of sensitized typhoid bacteria. In man, the systematic study of antibodies after the prophylactic injection of sensitized typhoid bacteria has been carried out most carefully by Broughton Alcock,[9] working under Bezredka's supervision. They found *no* agglutination or complement fixation in the individuals after two inoculations of sensitized living bacteria, while the power of phagocytosis was very high (6 bacilli per phagocyte in dil. 1:192). These results correspond fully with my animal experiments.

I have dwelt in detail upon this subject of antibodies because the general relationship between immunity and the detection of antibodies is still a problem for discussion. We all know that immunity can last long after the disappearance of known specific serum properties; then, too, we have often found that the serum from patients who died contained many antibodies, while those that recovered had very few. Leishman[9] considers an increase in phagocytic activity as the most important immunity. Klein[10] attaches more importance to phagocytosis than to agglutination and bacteriolysis. Most recently, Bull[11] has shown that agglutination does enter as the primary stage in the destruction of the bacillus typhosus and other bacteria.

Virulence and Toxicity of Sensitized Typhoid Bacilli.—Next in importance to the question of antibodies is the question of the virulence and toxicity

of sensitized typhoid bacilli. I already mentioned, under the heading of general reactions, that rabbits immunized intravenously with progressively increasing doses of sensitized bacteria withstood the inoculation much better than those inoculated with non-sensitized bacteria. Of seven rabbits thus immunized with dead non-sensitized bacilli, six died after the third injection, with symptoms of anaphylaxis; while of seven rabbits immunized with dead sensitized bacteria only two died. No explanation for this was offered, but Jobling[12] has since found that bacteria treated with serum do not absorb the antitrypsin ferments of the blood, the disappearance of which is associated with the phenomenon of anaphylaxis.

Guinea pigs inoculated intraperitoneally with lethal doses of dead sensitized bacilli remained alive, while the animals injected with the same dose of non-sensitized bacilli succumbed within ten hours, with severe symptoms of intoxication. Two hours after the injection, the rectal temperature of these non-sensitized guinea pigs was so low that it could not be estimated by the thermometer. The temperature of the animals treated with the sensitized bacilli rose slightly. Stained specimens of the peritoneal exudate from the sensitized guinea pig showed, two hours after the injection of the sensitized bacteria, no intact bacteria and an excess of leucocytes, for the greater part vacuolated. Later on, macrophages appeared, which took up the leucocytes, all this being strong evidence of positive chemotaxis. The peritoneal exudate from the non-sensitized guinea pig showed many broken up bacilli, but only few leucocytes.

Already in 1902, Bezredka[13] had found that the sensitized vaccine of typhoid and cholera bacteria (killed by heating one hour at 60° C.) when injected intraperitoneally in guinea pigs, was less toxic than the unsensitized vaccine. My above-mentioned experiments confirm this absolutely. More recently, Cecil[14] repeated these experiments, and, in addition, used *live*, sensitized bacilli. He also came to the same conclusion, namely: (1) Sensitized, living typhoid bacilli, when injected intravenously in rabbits and guinea pigs, are less virulent than non-sensitized living typhoid bacilli. (2) Sensitized typhoid bacilli, killed by heat, are in a similar way less virulent than non-sensitized, killed typhoid bacilli. (3) The most probable explanation for this difference is that sensitized typhoid bacilli undergo phagocytosis and bacteriolysis more rapidly than the non-sensitized bacilli.

Mode of Action of Sensitized Bacilli.—We may now discuss the mode of action of sensitized bacilli. Pfeiffer and his workers showed that the typhoid, as well as the cholera bacillus, belongs to a class of microorganisms whose poisonous substances are contained within the body of the bacillus, and are not easily given off into the surrounding medium in which they grow, as is the case, for example, with the diphtheria bacillus. This central substance was named the endotoxin, and was for a long time considered highly poisonous to the animal body. For example, death has been reported in the literature (Drigalski[15]) as having been caused by the sudden liberation of these endotoxins in typhoid fever after the use of a highly bacteriolytic serum. The term endotoxin had always been considered a misnoma, as it did not fulfill the requirements of a true toxin; *i.e.* it was devoid of antigenic properties, and its toxicity did not follow the rule of multiple proportions.

With this view in mind, associated with the animal and test-tube experiments mentioned in this paper, it seems permissible to the author to propose as a working basis the following explanation for the action of the sensitized bacteria: The typhoid bacillus consists of two parts: an inner, central or nuclear substance, the endotoxin, and an outer or enveloping protoplasmic substance or membrane. Injection of the whole bacilli stimulates antibodies first referable to the outer capsule, the usual bacteriolytic, agglutinating and complement fixation antibodies. After the production of these bodies they combine in vivo with the typhoid bacteria, *i.e.*, sensitize them in the circulation, and, with the aid of the complement of the blood, bacteriolysis occurs, resulting in the liberation of the central substance or endotoxin. This endotoxin is now capable of producing its own antibodies, the anti-endotoxins. When *sensitized* bacteria are injected the outer capsule is already saturated with its antibodies (agglutinins, bacteriolysins, complement fixation bodies, etc.); thus, none of these antibodies, or only a few of them, are formed; antibodies *are*, however, produced referable to the endotoxin, because as soon as the sensitized bacteria reached the circulation bacteriolysis at once occurred; the bacteria were immediately broken up by the aid of the complement, and the endotoxins were liberated and allowed to stimulate their antibodies. These antiendotoxins, as they may be termed for purposes of designation, are strongly bacteriotropic or phagocytic in nature. This has already been proven above by the examination of the serum of man and animals after inoculation with sensitized bacteria. Thus *sensitization may be considered a biological means for the liberation of endotoxin.* For years attempts have been made to liberate the typhoid endotoxins by physical and chemical methods of extraction or maceration of the bacteria. The methods of M. Hahn, MacFayden, Bezredka, Kraus and Stenitzer, Meyer and Bergell, are well known. Lüdke's adoption of the Gottstein and Matthes' method by ferment digestion has the same object in view. Sensitization accomplishes this end, in a manner more closely resembling that of nature. The endotoxin should not be looked upon in the light of the *only* poisonous element of the typhoid bacillus, because it has been shown above that rabbits and guinea pigs are not killed by the sudden liberation of large quantities of endotoxin after inoculation with multilethal doses of sensitized bacteria, while animals inoculated with same doses of the whole bacteria succumbed with marked symptoms of intoxication. Thus the outer portion of the typhoid bacillus must also have its poisonous constituents, if not even more so than the endotoxin.

I am fully aware that the theory of endotoxins had exposed itself to criticism during the recent split products and ferment period of Vaughan, but as some of this latter work has been shaken in its foundations by the works of Jobling, Bronfenbrenner,[16] and still more recently by the experiments of Novy, the endotoxin theory seems as yet to be the best working hypothesis for immunization with sensitized vaccines. I am glad to see that Nichols,[17] in a recent paper on sensitized vaccines, has arrived at a similar conclusion. Vaughan's explanation for the action of sensitized vaccines, as expressed by him in the very short but lucid paper of Stewart[18] seems to me, after all, to agree fundamentally with the view advocated above, but he

expresses it in terms of protein split products, instead of Ehrlich's nomenclature.

A few words should be allotted to Theobald Smith's[19] consideration of the mode of action of sensitized bacteria. He draws the analogy between bacteria saturated with their antibodies and toxin-antitoxin mixtures. Definite active immunity is produced with neutral toxin-antitoxin mixtures. A single such injection surpasses in effectiveness many doses of pure toxin. The mixture penetrates quite generally through the body, whereas the pure toxin is chiefly held at or near the place of injection. This diffusion tends to cause maximum antibody formation over a wide territory by a relatively very small amount of free or perhaps dissociable toxin in the toxin-antitoxin mixtures. Theobald Smith is inclined to believe that a similar phenomenon of diffusion occurs with sensitized bacteria. Naturally, this idea is purely theoretic.

Preparation of the Sensitized Vaccine.—Before taking up the practical application of sensitized bacteria in man, certain problems in the preparation of the sensitized vaccine merit a little additional discussion.

First, and most important, is the question of *live versus dead sensitized bacteria* and the posible dangers associated with the use of the former. As a rule, if there are several methods for producing immunity, that one should be chosen which approaches most closely the way that nature employs in producing that same immunity, provided that there are no harmful effects. In general, living virus has proven itself superior to a heated one in calling forth immunity. The less artificial manipulation of a vaccine during its preparation the better; thus we can destroy the entire efficiency of a vaccine by too prolonged or too high exposure to heat. From a study of antibodies, Schottstaedt found that vaccines killed by heat seem to be less active than those killed by the addition of phenol only. However, the possible *infectious power of a living sensitized vaccine,* or its *liability to produce a typhoid carrier state,* has kept many physicians from the use of the live virus. This is erroneous. Both of these factors are dependent upon the proper sensitization of the vaccine. An emulsion of live bacteria, but which have been *thoroughly and completely sensitized, i.e.* all bacteria saturated with antibodies, can do no harm, because, as has been so often said in this paper, when injected even in a massive dose the sensitized bacteria are quickly destroyed at the site of injection or in the circulation with the aid of the complement there existing; no live bacteria remain to cause a typhoid carrier state. Certainly, if the vaccine is not completely sensitized so that there are a great number of live bacteria ununited with their antibodies, these bacteria will not be destroyed when they are injected, but may multiply, and thus cause a typhoid infection. Even in this instance the almost immediate immunity produced by those bacteria which had been sensitized may destroy the unsensitized ones if they are not too numerous. The fact that cultures made from live sensitized bacteria show a profuse growth should not lead one to believe that the same thing will happen in animals or human beings when inoculated with living sensitized bacilli. Naturally, when live sensitized bacteria are cultured they will grow; they have remained alive and have not been destroyed, as they would be in a living body, by the help of complement. This is further proven by mixing living sensitized bacteria in one test tube with fresh normal horse serum, and in another tube with heated horse serum (the heating has destroyed the complement). Both mixtures are allowed to remain at 37° C. for one hour, and then cultures are made from each. After 24 hours' incubation a profuse growth will be noted from the test tube which contained living bacteria plus heated serum, while no growth occurs from the mixture of living bacteria plus fresh, non-heated serum. The latter contained sufficient complement to allow bacteriolysis, or destruction of the bacteria, even in the test tube. (Rowland.[20]) These experiments are in accord with my theory expressed above for the freedom from danger in sensitized bacteria, and disprove the statements made by many that sensitized bacteria are inocuous because they are easily and rapidly taken up by the phagocytes. In this test-tube experiment there were no leucocytes, so that phagocytosis was no element. The important factor is the *bacteriolysis* which takes place almost immediately with sensitized bacteria. The property of increased phagocytosis comes into play later by stimulation from the liberated endotoxin. The immediate bacteriolysis in the presence of complement explains also the important question relative to producing a typhoid carrier.

For several years after Bezredka first advised the method of the live sensitized bacteria he was met by opposition on the grounds that a typhoid-carrier state might possibly thus be produced, with the gall bladder as the central supply. (Editorial *Jour. Am. Med. Ass'n,* Vol. LXI, No. 20, p. 1914.) Bezredka[21] and others had reported on over thousands and thousands of cases without a single mishap of this kind. At the same time, this skepticism prevailed—unrighteously so. In rabbits, no gall-bladder lesions are produced after subcutaneous and intravenous injections of sensitized bacteria. If the sensitized vaccine were accidentally taken by *mouth,* as is possible from contaminated water or food, it may be inferred that disease *would* be produced, because under ordinary circumstances there would be no complement available in the gastro-intestinal tract for the completion of the bacteriolytic phenomenon. For the same reason, when sensitized vaccine is injected directly into the gall bladder of rabbits a purulent cholecystitis will be produced, and typhoid bacilli can be recovered from the pus as well as from the stools. In this instance the bile is simply a good medium for the multiplication of the typhoid bacilli. There is insufficient complement for the destruction of the bacteria. Even *after* rabbits have been immunized with Bezredka's vaccine, subcutaneously or intravenously, an active purulent cholecystitis from which typhoid bacilli can be recovered may be produced by direct gall-bladder inoculations with the live sensitized virus (Nichols[17]). This is to be expected; because the fact that rabbits have been immunized does not mean that their bile has developed typhoid protective bodies, or contains more complement. It is the complement and associated bacteriolysis which are the deciding factors in the inertness of the live sensitized vaccine, but the latter must be completely and properly sensitized. Typhoid infections, or typhoid carriers from the live sensitized vaccine, are thus entirely preventable if these immune reactions are kept in mind. Most of the sensitized vaccines on the market at present are made up of dead bacteria. At this stage of their use this may be a wise step, for it prevents any possible trouble that might arise from an im-

properly prepared live vaccine. With the great number of unreliable commercial firms or laboratories which have entered into this field, such poorly prepared vaccines would be more than probable. This would be a great hindrance to the further development of the live virus type of vaccine.

It may be of interest to dwell for a few moments upon the question of what *strain of typhoid bacillus should be employed* in the preparation of the sensitized vaccine. As you know, both the English and American armies have made up their non-sensitized typhoid vaccine from a single strain of the typhoid bacillus (known as the Rawling strain), which was obtained from the spleen of a soldier who died of typhoid in England in 1900. It was selected originally by Leishman for experimental use in preparing vaccines, not on account of its low toxicity or superior immunizing properties, but because it gave a remarkably even emulsion when washed off agar with salt solution (Leishman, Harrison, Smallman, and Tullock[22]). Recent examination (Nichols[17]) has shown this strain to be still definitely pathogenic for rabbits, in that it produces a typhoid cholecystitis when injected into the gall bladder of rabbits. It is relatively avirulent, as in general the recently isolated strains are more virulent; finally, it is distinctly toxic, and its efficacy is believed to depend upon this toxicity. Naturally, this same strain can be used in preparing the sensitized vaccine, and the serum for sensitization obtained from a horse that has been highly immunized against this Rawling strain. It has always been an open question which type of typhoid bacterium is most suitable for a vaccine (Broughton-Alcock[5]). Thus, Leishman, Russel, and Vincent have recommended a strain of feeble virulence; Wassermann has proposed a strain that calls forth the greatest response in antibodies; Bezredka has obtained contradicting results in trying the virulence of several strains upon animals. Thus, a strain taken from a carrier killed guinea pigs in one-sixth the quantity found necessary of a strain taken from a man after death from typhoid fever. The injection of the latter gave rise to an attack of typhoid in a chimpanzee, while an injection of the former had but a slight transitory effect on another chimpanzee infected. The clinical evidence, as furnished by the very convincing results in the English and American armies, favors the use of the Rawling strain in the preparation of the vaccine. The writer, however, has always been strongly of the opinion that a polyvalent typhoid vaccine, non-sensitized as well as sensitized, is the ideal preparation. In the prophylactic inoculation of my patients in private practice, and of the nurses and doctors at the German Hospital of New York, a polyvalent vaccine from eight different typhoid strains, isolated from the blood of different patients at the hospital, has been used. It would be rational to include also the two types of paratyphoid in the vaccine. This was primarily carried out by Kabeshima[23] in the Japanese navy. More recently, Vincent,[24] Widal,[25] and Chantemesse[26] speak favorably of this plan. Also in the treatment of typhoid fever with sensitized bacteria have I employed a polyvalent vaccine. Naturally, the polyvalent emulsion of bacteria has to be sensitized with a serum that has been produced by immunization with all of the different strains, in order that the very important factor of complete sensitization is assured. The failure in immunization, as has been reported in several civil communities after the use of the army vaccine, may possibly be accounted for by the lack of the polyvalency; *i.e.* antibodies, stimulated by the Rawling strain, were inert against the type of the typhoid bacillus causing the infection. This seems plausible when one considers the experimental evidences by Teague and Torrey,[27] Raskin,[28] and Garbat,[29] who showed that various strains of the same bacteria differ from one another in their specific antibodies, both agglutinins and complement fixation antibodies. Furthermore, the different action observed in sugar media of dextrose and mannite with the various strains of the typhoid bacillus proves slight individual peculiarities, and should be considered in favor of the polyvalency for both prophylactic and therapeutic vaccines. As for *autogenous* sensitized vaccine in the treatment of typhoid fever, this is somewhat impracticable. First of all, its preparation entails 4 or 5 days, and secondly, it is questionable whether the same patients' serum which it would be advisable to use in order to be certain of absolute sensitization contains sufficient antibodies. Immunizing an animal with this particular strain, and then using this serum for sensitization, would cause entirely too much delay. I have treated three typhoid fever patients with autogenous sensitized vaccines, but found no better response than from the use of a stock polyvalent sensitized vaccine.

It may be interesting from a laboratory worker's standpoint to say a few words about the different methods for standardization or enumeration of the vaccines. As a pupil of Sir Almroth Wright, I have followed his classic method of a comparative count between red-blood cells and bacteria in a stained smear made from a dilution of equal parts of the bacterial emulsion and red-blod cells. Sensitized bacteria are somewhat swollen, but are regular in outline and stain well. At the same time, I have found it simpler, in order to get an even smear, to standardize the bacterial emulsion before sensitization, as it was somewhat difficult after sensitization to break up the agglutinated clumps. One notes the total quantity of the original saline emulsion, a sample of which is used for enumeration, before the addition of the immune sensitizing serum; then, after sensitization and washing of the sensitized bacteria are completed, saline is added in a quantity equal to the original volume noted. In this way the standardization of the *un*sensitized emulsion holds true for the sensitized one. Bezredka suspends a quantity of bacteria grown upon the gelose surface of a Roux bottle, sensitized and washed, in 100 c.c. of saline; 1/10 c.c. of this emulsion is supposed to contain 500 million bacteria. Broughton-Alcock finds that if there are 500 million sensitized bacteria to 1 c.c., and this is diluted 1:40, 1/10 c.c. of this dilution will just fix 1/10 c.c. of guinea pig's complement titrated to just dissolve 1 c.c. of 5 per cent. sheep's blood. Dilutions can be thus arranged so as to come up to this standard. He further found that a 24-hours' growth on an ordinary agar slant approximates about 50,000 million bacteria. A Roux bottle is about 16 times as great.

Some observers (Schottstaedt[7]) employ the hemocytometer method, using the Helber blood-platelet counter, while others (Ichikawa[30]) employ arbitrary dilutions and dosage; thus the growth from one agar slant is sensitized and suspended in 10 c.c. of saline, and of this ½ c.c. is taken as the dose. All these methods probably have their wide margins of error, but give good results with each worker.

The last method of arbitrary dilution is simplest, but indefinite as to actual numbers. It seems to me that the original Wright method, with the above-described modification, aims at an accurate determination, and in the hands of one accustomed to it renders comparatively favorable estimations.

With these introductory experimental findings we are in a position now to discuss the *administration of sensitized typhoid vaccines* for prophylactic and therapeutic purposes. It may be of help to first compare its action with the *ordinary vaccines*. The inoculation of the ordinary dead typhoid bacteria as a prophylactic measure is now well recognized. The results in the American and English armies have been exceedingly satisfactory. The efficiency of this vaccine is easily explained on the basis of the biological indications to be met. The injection of the dead bacteria into a normal individual is usually followed by the production in great numbers of the various antibodies mentioned above: bacteriolysins, agglutinins, bacteriotropins, and occasionally complement fixation bodies. Some of these immune agents are probably capable of destroying the typhoid bacilli. If the inoculated individual is exposed to infection, that is, if live bacteria find their way into his body, they are readily destroyed, and will not multiply. Naturally, if the army of invaders is excessive, or the defense too slight, infection will arise in spite of the prophylactic measure. Fortunately, such instances are exceptional. The immunity is, therefore, explained on a bacteriolytic, and to a less degree on a bacteriotropic or opsonic basis. From clinical experiences it has been shown that immunity persists even after these immune bodies cannot be demonstrated any longer.

The prophylaxis attained by the injection of Bezredka's sensitized typhoid vaccine, living or dead, cannot, if sensitization is complete, be explained on identically the same principles, for as soon as the sensitized bacteria enter the normal system they combine with the complement of the blood and are broken up. The agglutinating and bacteriolytic antibodies and the complement fixation bodies are, therefore, either not produced at all or only in very small quantities; consequently, the reliance for protection must be placed on the phagocytic activity, stimulated by the liberated central substance of the broken-up bacteria, the so-called endotoxin. Thus the prophylactic immunity with sensitized vaccine is of a bacteriotropic character, while that with the non-sensitized vaccine is mainly of a bacteriolytic nature. Which one is superior cannot as yet be definitely stated. Thus far, many thousands of cases have been inoculated by the sensitized method, but sufficient data are lacking for comparison with the Wright method. Metchnikoff and Bezredka[23] have the laboratory experiments in their favor. Possibly this unfortunate war may furnish us more statistics, as members of the French army have been vaccinated with the sensitized virus. We know, however, that the reaction from the sensitized vaccine inoculation is much milder, and the immunity starts more rapidly; possibly the future will prove that it is also more lasting and secure. The doses employed are similar to the non-sensitized, *i.e.*, 500 millions, 1000 mil. 1000 mil. at intervals of about seven days, or 1000 mil. 2000 mil. at intervals of 10-12 days. The inoculations are usually given subcutaneously.

It may be in place here to consider a problem which has suggested itself to me, but which I have thus far been unable to carry out. If the injection of ordinary vaccine causes mainly a bacteriolytic reaction, and the administration of sensitized vaccine mainly a bacteriotropic response, would it not be advisable in prophylactic immunization to inoculate individuals with both sensitized and non-sensitized vaccines? In this way a combined form of immunity would be attained. As experimental basis for this suggestion I have shown that if the serum from rabbits immunized with non-sensitized bacteria is mixed in equal quantity with the serum from rabbits immunized with sensitized bacteria, this mixed serum was more curative for mice infected with typhoid bacteria than equal quantities of either serum alone. Naturally, it will be necessary to establish the best method for such mixed immunization: whether the two vaccines should be administered separately, and at different times, or whether they should be given at the same time, as would be accomplished also by an incompletely sensitized vaccine.

In the therapy of typhoid fever the use of the ordinary non-sensitized vaccines has not met with as favorable results as for purposes of prophylaxis. Up to the present time thousands of cases have been treated, but the beneficial effects in the majority of instances are not sufficiently marked to warrant the employment of vaccines as a routine procedure.

Recently, series of cases treated by *intravenous* injections of non-sensitized vaccine have been reported; occasionally a striking crisis in the course of the disease was observed. There are other reports, however, in which the effects have been distinctly harmful (or even fatal).

When the biologic basis for the possible therapeutic value of ordinary vaccines in typhoid fever is asked, the explanation is much more difficult and hypothetical than in the question of prophylaxis. Several factors are to be kept in mind: First, typhoid fever is a self-limited disease, running a typical clinical course, and probably associated with definite phases of immunity to account for its characteristic picture and self-limitation. Second, the number of bacteria existing in a typhoid patient is very great; they circulate everywhere, and stimulate the tissue cells continually, resulting in the formation of agglutinins, bacteriolysins, bacteriotropins, complement fixatives, etc. These antibodies are apparently produced very slowly, and are either not of sufficient number or are of a nature suitable to overcome the infection quickly. It usually takes four weeks or more to ultimately accomplish this. The reason for this prolonged period may possibly be ascribed to the structure of the typhoid bacillus. As we said above, this bacterium belongs to a class of microorganisms whose central substance, the so-called endotoxin, is liberated only after the bacillus has been broken up. This central substance also stimuates antibodies (antiendotoxins for purpose of designation) which are bacteriotropic in action and probaby important elements in the curative process of typhoid fever.

Were it permissible to divide the phases of typhoid fever from an immunological point of view, as is usually done from the clinical aspect, one would assume that the first stage consists of the multiplication of the invaded typhoid bacilli. Then, as a defensive reaction, the tissue cells stimulate the formation of antibodies (bacteriolysins, agglutinins, and but few bacteriotropins). The next phase sees the numerous bacteriolysins attack the bacte-

ria, sensitize them, and with the aid of the complement the micro-organisms are broken up and their endotoxins liberated. The latter, thus freed, further stimulate the tissue cells, with the result that other protective bodies (antiendotoxins) are produced in sufficient numbers to prevent any harmful effects and finally to overcome the infection. Naturally, these very schematic stages are not sharply limited, and do not fall within definite periods of time. Sluggishness, or absence of the proper reaction on the part of the tissue cells at any stage, is followed by a protraction of the disease, or even death; death by infection, if the bacteria multiply and are not broken up, due to insufficient response by the bacteriolysins, or death by intoxication if marked bacteriolysis has occurred, or has occurred so quickly that the liberated endotoxins are not in turn neutralized by sufficient antiendotoxins.

Keeping this explanation in mind, one can readily observe that the injection of ordinary vaccines in typhoid fever aims at nothing more than what the body is already doing with all its power, namely, the production of antibodies for the breaking up of the bacteria, the liberation of their endotoxins, and the ultimate manufacture of antiendotoxins. There may be cases in which the body cells are inactive, and are stimulated to activity and production of antibodies only after the inoculation of the vaccine. Here the ordinary bacterins are of undoubted aid.

As a general rule, however, it is best to relieve the sick body as much as possible of any active reaction. uring an infection the tissue cells are less responsive than during health, especially if the disease be a severe and prolonged one. That is why an efficient serum (passive immunity) would be the ideal form of specific therapy. Sensitized vaccines possibly hold a position between serum therapy and ordinary bacterin treatment. In the first place, they save the system from the strain of producing the primary antibodies for the destruction of the bacteria, since the bacteria are already laden with these bacteriolysins, agglutinins, etc., artificially supplied; and second, this provision hastens the stage of liberation of the endotoxins and the consequent almost immediate stimulation of the antiendotoxins, an important step in the recovery from the disease. With this explanation one readily sees the more rational basis for the employment of *sensitized* vaccine in the typhoid fever therapy.

As early as 1911-12 I treated a series of 17 typhoid cases with a vaccine killed by heating, sensitized with immune serum from convalescent patients, and given subcutaneously in doses of 200 to 500 million every 5 or 6 days. While the disease terminated by crisis in only a small percentage of cases, the impression was gained that the general course of the disease was milder. With my present knowledge of sensitized vaccines, I would unhesitatingly advise more frequent inoculations.

Ichikawa[30] reported a series of 87 cases treated with live sensitized vaccine administered intravenously. Ten platinum loopfuls of typhoid cultures were sensitized with 10 c.c. of immune convalescent serum for 5 or 6 hours in incubator, and the sediment, after being washed three times, was suspended in 100 c.c. of saline. Of this, ½ c.c., diluted with saline, was injected intravenously. He also treated 23 cases subcutaneously. Usually, one or two injections, when given intravenously, were sufficient to bring the temperature down to normal on the morning following the intravenous administration. A chill and increase in temperature usually occurred before the drop.

Boinet reported a series of 15 cases in 1913[31] and a series of 53 cases in 1914.[32] He used Bezredka's vaccine subcutaneously in increasing doses of 1, 2, 3 and 4 c.c. on 4 to 6 consecutive days. Usually, 3 to 6 injections were given, and the temperature came down to normal.

Szécsy[33] treated 112 cases with a live (not older than 12 days) vaccine, sensitized with immune horse's serum, and injected subcutaneously in doses of 1, 2, 3 and 4 c.c. on four consecutive days. Each c.c. contained 1/10 platinum loop of growth from an agar slant.

Fritz Meyer[34] treated 26 cases intravenously in a manner similar to Ichikawa, and came to similarly favorable conclusions.

The literature of typhoid fever therapy by means of sensitized vaccines intravenously is increasing very rapidly on account of the war. The above few reports are taken as examples of the distinctly encouraging results. Other reports are by Biedl,[35] Eggerth,[36] Sladek and Kotlousky,[37] Boral,[38] Holler,[39] Lang, Luksch and Wilhelm.[40]

With the subcutaneous method of Boinet or Szécsy, sharp reactions were not the usual termination, but the disease ended by lysis. On the whole, the impression was gained that the inoculation rendered the general course of the disease milder and shorter and the complications and relapses fewer. I would be inclined to adopt the intravenous method of treatment even though the reaction following the inoculation is sometimes severe.

The fundamental work of Gay on sensitized typhoid vaccine has not been overlooked. His recent very complete contribution[41] holds forth distinct promise for the vaccine therapy of typhoid fever. The preparation employed by Gay is, however, a modified sensitized vaccine; one from which the endotoxin is extracted, thus differing in principle from the usual sensitized vaccine under discussion.

We are still on the very lowest step of the ladder of sensitized vaccines as a therapeutic measure in typhoid fever. Experience must teach us the accuracy of the dosage, the frequency of inoculations, the mode of inoculation, the contraindications, etc., etc. Only then shall we know definitely the value of this form of treatment.

I wish to warn you, however, how guarded one should be about the results of any form of specific therapy in a disease like typhoid fever. Normally, all types of illness may exist. Clinicians have frequently observed that during some typhoid seasons the patients will present mild infections without any special treatment whatever. One could attribute beneficial effects to vaccine treatment with certainty only if rapid improvement or crisis in the course of the disease would set in soon after the inoculation. Such acute changes can be expected more often by treatment with a specific serum than with a vaccine, for by the former (passive immunization) antibodies are injected ready for neutralizing the poison; while in the latter instance the antibodies must first be manufactured by the tissue cells. This ever-existing factor in vaccine therapy makes it absolutely necessary to start the treatment in typhoid fever as early in the course of the disease as possible, at a time when the reactive power of the individual is still responsive and unimpaired by the infection.

DIATHERMIA IN THE TREATMENT OF TRIFACIAL NEURALGIA.*

By HEINRICH F. WOLF, M.D.,

NEW YORK.

CHIEF OF THE DEPARTMENT OF PHYSICAL THERAPY, MOUNT SINAI HOSPITAL AND DISPENSARY.

I HAVE used the diathermia treatment in cases of trifacial neuralgia for more than two years. Looking over the literature I have found that Nagelschmidt has published his results of this treatment with diathermia and Dr. Q. C. Geyser has published in *American Medicine*, 1913, Vol. 8, page 606, a report on one case which he treated in the same way. I am publishing my experience firstly on account of the good results I have obtained in many cases, and secondly because this experience has taught me which type of cases are amenable to treatment.

First a few words concerning diathermia. Diathermia, or thermopenetration, is a method which consists in heating the tissue by means of the high-frequency current. The ordinary high-frequency current cannot be used properly for this purpose, as the tension is too high and the irritation too marked by the sparking. It would take too long, however, to go into the detail of the technique and I have to refer to other publications.

The conservative treatment of trifacial neuralgia of the more severe kind has been considered a hopeless one. The fact that frequent remissions occur in the severity of the pain, especially when the disease is only of recent date, has induced a great many physicians to exaggerate the value of certain methods such as galvanic electricity or the static breeze, but we can say with a large degree of certainty that a fully developed ticdouloureux has rarely if ever yielded to conservative treatment, and we know that even injections of alcohol have failed in a large percentage of cases, or have given only temporary relief.

Under such circumstances it might be of value to report the results, which I have had in the treatment of severe cases of trifacial neuralgia with diathermia.

Case I.—February 10, 1915. A. F., aged about 40 years, has suffered from severe attacks of neuralgia, in the right supraorbital region, for a number of years. The present attack started ten days ago. The pain was continuous, and did not respond to medical treatment of any kind. The patient had not slept for ten days. This pain disappeared after the first treatment and the patient slept for one hour, after which the pain returned, but in a lesser degree. After six treatments, the patient was entirely free from pain.

Case II.—D. L., about 35 years old, suffered for nine years from typical ticdouloureux, the attacks occurring every few minutes, especially in the infraorbital region of the upper jaw. There was typical paresthesia in the mouth. The attacks were rare in the beginning, gradually getting more frequent and of longer duration. The patient was injected twelve times and operated upon on Feb. 10, canal being opened and injected. He did not improve, and was about to be operated upon again, but the day before the operation was to take place I was sent for to see him. At that time he was having attacks every five to ten minutes, and was sleeping badly. We commenced daily treatments, and about ten days later the patient had attacks only twice a day; he slept well, but had pain when eating or talking. After twelve treatments the pain had entirely gone, and the patient was presented in the Yorkville Medical Society. About six weeks later the patient had a recurrence and received three more treatments. I am not able to ascertain whether he was permanently cured.

Case III.—Mrs. E. B., aged 72, had pain in the left side, especially the lower jaw, very severe during the last six months; her nights were sleepless on account of the pain. The duration of the attacks was from thirty minutes to three hours. Alcohol injections were given six weeks previous to this treatment, but without result. The first treatment was given on March 14, 1915. On the following day she reported herself a great deal better, having had but one severe and one light attack. On the 16th there were some very light attacks, but no severe ones. On March 22 she had attacks the whole of the afternoon and from one to two and from five to six on the following morning. There was a burning sensation in the mouth. On March 24 there were light attacks from 7 P.M. to 1 A.M., and on March 25 stronger attacks at 5 A.M. No treatment was given for three days. March 28, somewhat severe and prolonged attacks. March 29, light attacks only in the morning and evening. The patient disappeared for a time and later was admitted to the Mount Sinai Hospital according to prearranged plans (having been put

*Read before the Society for the Promotion of Physical Therapy, New York, May 11, 1916.

on the waiting list). She was then found to be so much better that it was not necessary to give her surgical treatment.

CASE IV.—Mrs. D. F. (recommended by Dr. Abrahamson) had had pain for six months in the middle and lower branches, the attacks being very frequent, with hardly any painless intervals; she could not sleep. There was tenderness at the supramaxillary and inframaxillary foramina. We commenced treatment March 23, 1915. On the following day the condition was the same. On March 25 she was slightly better, and on the following day was much better. Treatment was then discontinued, on account of an intercurrent disease. The patient returned after two weeks in greatly improved condition. She received in all ten treatments, and is now apparently cured.

CASE V.—Mrs. S. S., 51 years (Dr. Abrahamson), had had pain for eight years, without known cause, in the right infraorbital region; it formerly occurred in attacks, but latterly pain has been constant. Eating and drinking cause excruciating pain. She sleeps sometimes four or five hours, lying down seeming to relieve the pain. After four treatments the patient was greatly improved, having only slight pain in the morning. She was treated for a month with varying effect. There was a recurrence during the summer and the patient received a few more treatments. The ultimate result is doubtful, as the *x*-ray picture shows a bony tumor in the neighborhood of the nerve at the base of the skull. This patient, who had been treated by Dr. Abrahamson for years, has not reported for treatment at his clinic since.

CASE VI.—Mr. M. (Dr. I. Strauss), has had severe pain in the upper branch for one month, the attacks occurring every ten minutes. Improvement commenced after first treatment. The day following the second treatment the patient had only three attacks. Discharged after four treatments.

CASE VII.—Mrs. W. N. (Dr. I. Strauss), had had light attacks of neuralgia for a number of years. The pain disappeared after three treatments.

CASE VIII.—Mr. N., 38 years old (Dr. I. Strauss), has had very severe pain during the last seven years, the pain being continuous, with severe exacerbations about twice a day. Two injections did not give any relief; he cannot eat or talk without pain. The patient received about twenty applications without any appreciative relief and discontinued the treatment.

CASE IX.—Miss W. (Dr. W. J. Maloney), had been ill for seven years, the pain being practically continuous, with remissions during the night. A number of alcohol injections were given by prominent neurologists without effect. The treatment brought relief for about an hour, but owing to the patient having to leave the city, it was discontinued after eight sessions. No conclusion could be drawn from this case on account of the limited number of treatments, but I have included it to make my record complete.

CASE X.—Mr. M., referred to me by Dr. Carr. The patient has a long history of suffering. During the past six years he has had attacks of the most severe type of trifacial neuralgia on the left side in the middle and lower branches, alternating with free intervals, which are becoming steadily shorter and the attacks always longer. Patient always describes them as spasms. At the beginning of the war he was in Munich to receive alcohol injections, but left the country immediately before the treatment was commenced. His last attack has continued steadily for six months. *X*-ray examinations revealed caries of the alveolar process, which was operated upon by Dr. Carr. In spite of the operation, the pain continued and the resection of the ganglion Gasseri was contemplated. As a last resort diathermia was used, which completely relieved the pain after ten days. The patient was presented before the Neurological section of the Academy of Medicine, where I expressed my doubt whether the relief of the pain was due to the usual remission or to the treatment. A few days later the patient again began to have slight pain, which, however, has practically disappeared after a few more treatments. The character of the pain changed, it being more a sensation of soreness, without spasm. The patient returned four months later with an unusually severe attack which, according to his previous experience, should have lasted four or five months. He had about 200 spasms (as the patient describes it) in one night, and seemed to be in a desperate condition. After four treatments the pain entirely disappeared. The wound in the upper jaw has not yet healed.

CASE XI.—Mr. Sch. has had a very severe form of trifacial neuralgia of the upper and middle branches for twelve years, alternating with remissions. In the beginning there was swelling of the face. Two teeth were extracted and the pain disappeared. Two years later the pain returned and lasted six weeks. The attacks were slight. Again two years later there was another attack which lasted a few months. Three weeks ago the pain returned with unusual severity. It began at four A.M. and lasted for twelve hours. It was so severe that the patient actually crawled on the floor. An alcohol injection was given without effect. Diathermia treatment was then commenced, with splendid results. The patient was enabled to resume his work after one week, even though he still has slight attacks off and on. The *x*-ray picture was negative.

CASE XII.—Mrs. G. L., has had neuralgia in the upper and middle branches for three years, especially severe during the last six months, without intermissions; the exacerbations occur periodically. Received injection in Mount Sinai Hospital with no result, and was then referred to me. After four treatments patient was so much relieved that she could bear the pain very easily. The treatment has been continued with excellent result.

CASE XIII.—Mrs. T., 50 years of age. The patient's history, as told by herself, is as follows: She had a severe attack of typhoid twenty-six years ago, and has never been quite well since. About twenty years ago pain developed in the right side of the face (always in the lower jaw). In the beginning the pain was very severe, and she had attacks of thirty minutes' duration, at intervals of two to four hours. This occurred about once a year and lasted for about three or four weeks at a time. The attacks became gradually worse until the pain became practically continuous throughout the time mentioned. It has been very bad for ten years. About nine years ago she was treated with injections, but she was unable to tell me what the substance was; it could not have been alcohol, as the injections were given daily with small needles. The attacks then became lighter and less frequent, and she gradually became better. The condition remained much the same for nine years, but since last September the patient has had very frequent attacks—in fact, the pain has been nearly continuous, with very little sleep at night. We commenced treatment three weeks ago, and improvement began three days later, there being no attacks sometimes for two or three hours, even when talking. The patient was able to sleep some nights for six or seven hours without interruption. The attacks are now usually very short, lasting only a few seconds, and the pain is quite mild. The treatment will be continued. Two days ago she complained of chills which start during the night, followed by attack of heat, and sometimes without the latter. Upon investigating I discovered that she had suffered with malaria fifteen years ago, five years after the beginning of the present trouble. I have had no opportunity in this short time to examine her blood for malaria plasmodia, but I am aware of the possibility of their presence. The fact that the attacks began long before the malaria started is not quite sufficient to exclude the connection, as the malaria might have been unrecognized.

Though not belonging to this class, I should like to report a case that was brought to me by Dr. M. Mrs. M. suffered from a sudden attack of neuralgia in the middle branch of the trigeminus. Diathermia treatment stopped the pain after ten minutes and there has been no recurrence.

If we try to analyze the records of these cases we note that those patients who were sick only for a short time were relieved permanently and quickly. Patients who complained of genuine tic douloureaux, with free intervals, reacted well. Old people, in whom the disease seems to be due to arteriosclerotic changes in the vasa nervorum, seem to be greatly relieved by this treatment. Trifacial neuralgia in adults, which causes continuous pain with exacerbations, with paresthesia in the mouth, and which are evidently due to degenerative changes in the ganglia, seem to be refractory to the treatment. The difficulty with these cases is that through the long duration of disease the nervous system has been to such an extent deranged that it is difficult to

induce them to take the treatment for any length of time. They are too quickly discouraged and become unmanageable. Injections of alcohol into the nerve seem to spoil the chances of recovery, as Nagelschmidt has already pointed out; but it has occurred to me this conclusion may not be correct, as the injections are given only in very severe cases of long standing, which yield neither to injections nor to any other form of treatment, except dissection of the ganglion Gasseri.

In one very interesting case the Gasserian ganglion was resected by Dr. Elsberg, and the occurrence of complete anesthesia proved that the operation was successful, but the patient still complained of considerable pain. The condition was improved by diathermia.

So far as the technique is concerned, I wish to point out that we have to try to apply the electrodes in such a way that the affected ganglion shall be located between the two. The best way is to apply one at the back of the neck, at the base of the skull, and the other over the eye, which is first covered with a thick layer of cotton saturated with salt solution, or on the upper jaw.

We seldom use more than 1000 milliamperes and generally only 700. The duration of each treatment is from thirty minutes to one hour.

In conclusion I wish to say that diathermia is a very valuable agent in the management of trifacial neuralgia, and it should always be tried before less conservative treatments, such as alcohol injections or section of the nerves or the ganglion, are resorted to.

None of the patients mentioned as improved or cured have returned to the physicians who recommended them or to me, which may be regarded as proof that the improvement continued.

161 West Eighty-sixth Street.

EMPLOYMENT OF PERSONS IN THE ARRESTED STAGE OF TUBERCULOSIS.*

By JAMES S. FORD, M.D.,

WALLINGFORD, CONN.

ASSISTANT PHYSICIAN, GAYLORD FARM SANATORIUM.

One of the most important questions that the tuberculosis worker has to face is what employment the arrested cases may safely take up. This question has been argued for a great many years and even to-day there is not unanimity of opinion.

The advice given years ago that all arrested cases must seek outdoor employment, irrespective of what that might be, is still given by many men in general practice. There has been in the last few years a decided trend among those engaged in the treatment of tuberculosis to send their patients back to their former ocupations provided, of course, they were not harmful. From an economic point of view this question is of vital interest, bearing as it does upon the income of the family thus determining what living and housing conditions will be available. Considerations that must enter into the advice given the arrested cases are whether the place of employment is going to be in a crowded city or in a small town and whether it will be in a poorly lighted and poorly ventilated building, or in the modern steel and concrete type furnishing a maximum amount of fresh air, sunlight, and efficient ventilation.

All too often these factors are not thought of and what may be perfectly safe employment under ordinary conditions becomes most harmful under conditions of overcrowding and poor sanitation. Furthermore, employment that may be safe and healthful in a well-ventilated shop becomes a menace to the discharged patient when attempted in a tenement home. A great deal of stress is put upon the danger of various occupations but very frequently litle or no attention is paid to the housing and living conditions of the individual. We have discovered time and again that the working conditions of many of our former patients were all that could be asked for but that their housing conditions left very much to be desired. Under such circumstances the employment cannot justly be blamed for a relapse and yet I dare say that but little attention is given to this other important factor I have mentioned in determining the cause of the breakdown. It is supreme folly to treat a man six months to a year in a sanatorium, then send him back to a shop or office where everything is ideal from a hygienic standpoint and have him live in a home where conditions are most unhealthful. Such a patient is almost certain to relapse and his occupation will have nothing whatever to do with it. The time and money sent in obtaining an arrest of the tuberculous process is entirely wasted.

The question has frequently been brought forward as to what occupations are harmful to the arrested case and while there are, no doubt, a few that would fall into this classification, I am convinced that very often the personal habits of the individual are the predisposing factors in the relapse for which the employment bears the burden of blame.

We hear a great deal of the so-called dusty occupations predisposing to tuberculosis and being absolutely unsafe for patients to resume. However, in the modern factories with their various appliances and exhausts to carry off irritating dust, the element of danger to the returned worker seems to be reduced to a minimum. On going over our records we find that we have had a great many more housewives as patients than representatives of all the dusty trades put together and very little objection is raised against the housewife, whose disease has become arrested, returning home to resume her household duties. Surely no work is more wearing or has longer hours than the keeping up of a well-regulated household. Standing in front of a hot stove preparing meals is certainly enervating and the exposure that so frequently occurs going out into the cold from a hot kitchen is a decided factor that predisposes to "catching cold" with a consequent lighting up of the arrested process.

In sending patients back to work a most important injunction to be given them is that they continue to obtain a maximum of rest. If you can thoroughly impress this advice upon discharged patients—that every hour not spent working must be spent resting for the first year, at least, following the restoration of their health—employment will be found not to be such a factor in relapse.

The decision as to sending a patient back to work is often a difficult one to arrive at and this especially is true when the individual is an unskilled hand. The first advice he frequently receives from misguided relatives and his family doctor is that he must seek an outside job and too often do we hear that much-talked-about, but never-realized "light work on a farm." I have no hesitancy in saying that the patient taking an outdoor job where he will

*Read before the Third Annual North Atlantic Tuberculosis Conference, Newark, N. J., October 21, 1916.

be exposed to the elements, runs a fifty per cent. greater risk of relapse than does the man who takes inside employment. The farm colony idea, so enthusiastically championed by Forster, Sloan and others, is not practical, due to the difficulty in interesting the average patient in farming. I have no argument whatever with the advocates of this form of employment when used for therapeutic purposes and when the workers are under the care of a well-trained physician. However, to have these patients take up farming after leaving the sanatorium, thrown as they will be upon their own resources and free from any medical supervision, is fraught with danger. The hours of work on a farm are long, there is exposure to all kinds of weather, the worry is great and very often, especially in the beginning, the financial return is small. With this last factor in mind you must realize that the housing and living conditions are bound to suffer. This myth of light work should have been exploded long before this, for the only thing light about the occupation of farming is the pay.

It is a big mistake to take your patient from an indoor position and urge upon him the taking of an outdoor occupation. The field in this regard is limited to canvassers, collectors, teamsters, trolley and railroad jobs, chauffeurs, watchmen, foremen of construction gangs, and timekeepers. The last three might be considered suitable employment for the arrested case, being exposed to the elements less than any of the others mentioned, but the hours would in all likelihood be long, the pay small, less desirable housing be obtained and poor living conditions ensue. Then, added to this, would be the anxiety over the possibility of not making good in the new employment, the bringing into play of previously unused muscles, with consequent marked fatigue, and the worry that would go with the diminished income.

The most logical plan is to send the patients back to their old occupations, for here the mental strain is decidedly less, they would be assured of a larger income than would be the case were they to engage in a new field and they could enjoy better housing and living. Furthermore, they would be working with and for people who in all likelihood would make things as easy as possible for them.

An ideal arrangement is to send the arrested cases back to their old employment, beginning with part time work and keeping them under medical supervision. We have been able to have that plan adopted by a few of the manufacturing companies of our state and it solves the question of employment for the discharged patient as no other plan does. The returned worker reports back to us for periodical examinations and his working hours are increased only on our recommendation. In this way the individual is able to try out his strength and by gradually adding to his working time suffers no bad effects.

There can be no doubt that indoor work for the discharged tuberculosis patient is much to be preferred. On going over the records of Gaylord Farm for the past twelve years we discovered that of the patients who had returned to indoor employment, but 20 per cent. had relapsed; that of those who had returned to outdoor employment, thirty-nine per cent. had relapsed; and that of those who previous to their illness had indoor positions but after discharge had taken up outdoor work, forty-two per cent. have had a setback. The work indoors as a rule is not as strenuous as outdoor occupation and most of it can be done sitting down, which is a decided factor in the prevention of undue fatigue.

I want to mention an occupation that I believe offers much to many of our discharged young women patients—that of the trained tuberculosis nurse. Many of the patients who would have to return to employment where long hours prevail, or to boarding places where living and housing are not up to the requirements that the discharged patient should have, will find here a means of prolonging their life, of earning a good livelihood under favorable auspices and have the satisfaction of doing a good work. There is undoubtedly a distinct field in sanatoria for the trained tuberculosis nurse. However, I do not believe, as some do, that she has a place in public health work. Aside from the fact that her training is not general I feel that such work is much too strenuous and wearing for any one with even a slight amount of tuberculosis.

The problem of employment is rather easily solved when you are dealing only with the incipient cases. By far the great majority of these can safely return to their original occupation and by living a God-fearing life for a year or so will be as good physically as any healthy man. Of two hundred and thirty-six incipient cases discharged from our sanatorium, two to twelve years ago, one hundred and ninety-three, or eighty-two per cent. are alive, well and at work.

The problem of employment is not so easily solved for *some* of your moderately and far advanced cases. For these people part time work, not of too laborious a character, should be obtained; and no doubt through the agencies of employment bureaus, private, municipal and state and through the organized charities associations such work could be found. The moderately advanced and far advanced cases present a tremendous economic problem as the percentage of these cases that can keep at occupations of any kind suffers markedly when compared with the incipient group. Of six hundred and ninety-seven moderately advanced cases discharged in the past twelve years, three hundred and seventeen, forty-five per cent., are alive and at work, while of one hundred and seventy-nine far advanced cases discharged in the same length of time but thirty-three, eighteen per cent., are working.

There is one other factor that will help solve this much mooted problem of employment of these arrested cases and that is an early diagnosis of their disease. I have shown you how large a percentage of our incipient cases have been able to return to their own work and I feel sure that these figures can be duplicated elsewhere throughout the country. In addition to this the preaching of improved home hygiene and better living will have a most beneficial influence. The well-known work of The Home Hospital in New York City has shown us what improved housing will do for many cases of tuberculosis. If then we could have these model tenements built in the large cities where these arrested cases could live and have manufacturers appreciate the enormous value of fresh air, sunlight and efficient ventilation in their plants, I feel sure that the question of employment of arrested cases would not prove the bugaboo that it now so frequently is.

Myelo-erythrocytoma Mediastinicum. — Moreschi under this term describes tumors of the mediastinum which consist of rapidly proliferating and infiltrating erythroblasts and megaloblasts and occur with the blood state erythroleucemia. In more familiar language the tumor was a lymphosarcoma.—*Il Policlinico.*

HEMATURIA AND PYURIA.

By S. WILLIAM SCHAPIRA, M.D.,
NEW YORK.
PROFESSOR OF GENITO-URINARY SURGERY, FORDHAM UNIVERSITY SCHOOL OF MEDICINE; VISITING GENITO-URINARY SURGEON, SEA-VIEW AND SYDENHAM HOSPITALS.
AND
JOSEPH WITTENBERG, M.D.,
BROOKLYN.
INSTRUCTOR OF GENITO-URINARY SURGERY, FORDHAM UNIVERSITY SCHOOL OF MEDICINE; ATTENDING GENITO-URINARY SURGEON, BEDFORD DISPENSARY AND HOSPITAL, BROOKLYN, N. Y.

HEMATURIA occurs with bleeding from any cause in or into any part of the urinary tract. The causes are local and general.

Under local causes we have: (*a*) Traumatism of the kidney, bladder, or urethra, by external violence, by calculus, by injury with instruments, or by the scratching with crystals in concentrated urine. (*b*) Inflammation or congestion, which occurs with infectious diseases, from exposure or with the elimination of irritating drugs like cantharides or turpentine. (*c*) Ulceration: simple or tubercular, occasionally leuetic. (*d*) Rupture of dilated veins, in the papillæ of the kidney in the ureter or in the bladder. (*e*) Tumor. (*f*) Parasites, as bilharzia or filiaria. These are very rare in this climate. (*g*) Under the head of congestion, we should include the congestion resulting from the complete emptying of an overdistended bladder. The support which is given to the congested vessels in the bladder wall is suddenly removed and they bleed slightly.

General causes include dyscrasia of the blood which we find with: (*a*) the specific infectious diseases. (b) Hemophilia, purpura, and leucemia, (*c*) Phosphorus poisoning.

Essential hematuria comes under the heading of those resulting from general causes, but the fact is that in the majority of cases of what we call essential hematuria careful examination of the kidney shows that the condition is not idiopathic at all, the kidney showing some interstitial change or change in the blood-vessels, commonly dilatation of the vein, at the apex of a pyramid.

Peculiar cases of family hematuria have been observed where no other symptoms were present in life and no lesions were found in the kidneys post mortem.

The amount of blood in the urine varies from a few blood cells, to what appears to be almost pure blood. The term hematuria, as commonly used, implies that sufficient blood is present to be noticed microscopically.

Diagnosis of Hematuria.—Hematuria must be distinguished from coloring of the urine after ingestion of certain substances, especially rhubarb and senna, or dyes in candy. The microscope is the simplest and best means to exclude them all.

Diagnosis of the seat of the hemmorhage and of its cause is made by: (1) the history of the case and the symptoms; (2) the time of appearance of the blood, whether at the beginning or the end of urination; (3) the appearance of the urine and by its constituents, and (4) physical examination.

For example, a history of attacks of renal colic, made worse by jarring, will point to renal calculus. Hematuria appearing and stopping without apparent cause, and scanty in amount makes us think of tuberculosis of the kidneys or of the bladder. A profuse hematuria appearing and stopping without apparent cause, immediately suggests a tumor. The presence of a stab or a gunshot wound or signs of other severe trauma at the region of the kidney or bladder with the hematuria clearly point to injury of the kidney, just as a profuse purulent discharge from the urethra, with pain or urination accompanying the hematuria, shows a urethritis.

The time of the appearance of the blood is of assistance. Blood appearing with the first part of the stream shows the hemorrhage comes from the urethra. Terminal hematuria means that capillaries at the posterior urethra or at the trigone have been injured by the spasm of the muscles in squeezing out the last few drops of urine. Urine that is well mixed with blood shows hemorrhage above the internal sphincter or in the posterior urethra with the blood draining back into the bladder.

The appearance of the urine, its color, clots, mixture with pus, etc., teaches much. In blood which has long been in contact with acid urine, the oxyhemaglobin is changed into methemaglobin; the blood is therefore dark. In alkaline urine, the blood regains its light color. Dark colored blood in the urine is therefore apt to come from the kidney, the urine being usually acid and the mixture of the blood with the urine being long and intimate. When the bleeding is from the bladder, the condition causing the hemorrhage is apt to be accompanied by alkaline urine: also all the blood not having been in contact with the urine for a long time is therefore apt to be light in color whatever the reaction of the urine. Blood clots in the form of ureteral casts, show hemorrhage above the bladder; blod clots formed in the urethra are broader than ureteral casts. Blood clots of irregular shape show that coagulation takes place in the bladder, but they do not show the source of the blood—whether the kidney, the ureter, the bladder, or the posterior urethra.

Differentiation is made between hemorrhage from the bladder and that from the posterior urethra, by washing the bladder clear, and filling it with clear salt solution. If the bleeding is from the bladder, all the solution is soon colored; if from the posterior urethra, whatever part of the fluid is withdrawn through the catheter is clear, and that part passed by the patient is colored, especially the last part, from expression of any blood present in the posterior urethra, with the last drops of urine.

Other contents of the urine may point to the cause or to the location of the lesion. We may find: (*a*) tumor fragments or cells, (*b*) concretions of stone or numerous crystals, (*c*) renal casts and abundant epithelial cells from the various parts of the urinary tract, (*d*) albumin, which is always present with hematuria, being derived from the blood serum. If however the albumin is out of proportion to the amount of blood the kidneys are probably involved.

The cystoscope is the last and the most certain means of determining whether the bleeding is from the bladder or from the kidney, and, if the latter, from which kidney. If from the bladder, it will also show the cause; if from the kidney, the ureter catheter passed into the renal pelvis may bring away a piece of tumor or withdraw tuberculous urine, or if coated with wax, may show the scratches made by a calculus.

Pyuria.—Pyuria results from some purulent inflammation along the course of the urinary tract: or the emptying of pus from some neighboring focus into the urinary tract. The suppuration results from some infection, simple or tuberculous, or which complicates a calculus, tumor, or stricture.

We must first make sure that turbidity of the urine is due to pus; once satisfied as to that, we look for the site of the suppurating focus and for its cause.

We will review the things from which we must differentiate pus and the simple methods used.

The cloudiness produced by urates, disappears on warming the urine; phosphates clear up on the addition of a little acid; carbonates clear up by the same method with the evolution of some carbonic acid gas; chyluria clears up on shaking the urine with ether; mucus precipitates on the addition of a little acetic acid, and redissolves by adding an excess of the acid after the urine is first diluted with an equal volume of water.

The haze of bacteriuria is not affected by heat nor by chemicals and the germs are not precipitated by the centrifuge unless alcohol is first added to the urine. The urine is opalescent and often has a foul odor.

A simple chemical test for pus is adding a solution of a caustic alkali to the urine and twirling the glass; the pus is coagulated into slimy ropy masses. If the sediment is allowed to settle, the fluid above decanted and a solution of caustic alkali added, the coagulum produced will adhere to the bottom of the glass if that is turned upside down.

We make a diagnosis of the site of the suppurative lesion and its cause by the history of the case, by the symptoms present, and by the physical examination as mentioned in the section on hematuria. Of these we will mention only a few points that are so characteristic of certain pathological conditions as immediately to suggest these conditions.

Intermittent pyuria, where the urine is perfectly clear at certain times and suddenly becomes full of pus, then clear again, shows a condition in which there is a temporary obstruction to the escape of pus from a suppurating cavity. A strongly suggestive accompanying symptom is that the patient presents septic symptoms when the urine is clear, that is when the pus is retained, and these septic symptoms promptly subside with the removal of the obstruction and the discharge of the pus in the urine. The usual condition in which this is present is a pyonephrosis complicating a calculus or a prolapsed kidney, where the ureter is at times obstructed by the calculus or by a kink from displacement of the kidney. An inflamed diverticulum of the bladder may give the same symptoms as will occasionally a seminal vesiculitis, the pus being poured into the bladder at intervals.

We will consider the characteristics of the urine more particularly and the direct examination of the urinary tract. Pus showing in the first glass and not in the second means that the source of the pus is in the anterior urethra. A turbid first and second urine show either an acute posterior urethritis (that is habitually accompanied by an acute anterior urethritis) where the discharge is profuse enough to flow back into the bladder, or a purulent process above the vesical sphincter.

Renal pus is characterized by settling on the bottom of the glass in a flat layer like heavy sand. The fluid above is slightly cloudy from a little pus and bacteria. Since chronic renal irritation, of which this pus is an indication, is usually accompanied by a polyuria, the urine is of low specific gravity. Pyuria of renal tuberculosis shows a light color, often like that of lemonade or lighter; while calculous pyuria is apt to be dark from blood.

Bladder pus is mixed with considerable mucus, so that it floats well and becomes somewhat viscid on standing. Pus from the urethra is also light and fluffy, but is mixed with less mucus, and therefore settles more readily. In neither cystitis nor urethritis is polyuria present; the specific gravity is therefore not low, as with pyuria of renal origin.

Alkaline pyuria was formerly thought to be of visical origin and acid purulent urine from the kidneys. We now know that the reaction of the urine depends on the causative germ. Infection by the *B. coli*, tubercle bacillus, gonococcus and *B. typhosus* is accompanied by acid urine, while infection by the staphylococcus, streptococcus or *B. proteus* results in decomposition of the urea with the formation of ammonia. It is true though, that infection by the ammoniagenic germs is much more common in the bladder than in the kidney, in which it is quite uncommon.

Cystoscopic examination and ureter catheterization is the last refinement in the diagnosis of the source of pus in the urine when that is above the internal sphincter.

The condition of the bladder wall and the presence or absence of diverticula are seen. The efflux from the ureteral mouths is seen to be turbid or clear. When the pus from a kidney is too scanty to be noticed in this way, ureteral catheterization will secure the urine from each kidney separately for careful examination. In rare instances where some neighboring suppurating mass empties into the ureter, the catheter, if passed into the renal pelvis, will withdraw clear urine, while the urine as it comes from the ureteral mouth is contaminated.

The causes of the suppuration may be judged at times by the other urinary findings. Concretions of urinary salts, pieces of tumor, considerable epithelium from the bladder, from the renal pelvis, or from the urinary tubules are good guiding signs. A trace of albumin is due to the pus itself; considerable albumin points to disease of the kidneys.

RHINAL PREMONSTRATION OF TUBERCULOSIS.

By J. A. HAGEMANN, M.D.,

PITTSBURGH, PA.

OTO-RHINO-LARYNGOLOGIST TO THE PITTSBURGH HOSPITAL.

PREDILECTION to determinate channels of exit from the human body is evidenced by a number of substances which have medicinal applicableness. Some of these display the idiosyncrasy of producing considerable disturbance at their respective areas of departure. One need but recall the hydragogue action of elaterium, or the renal and vesical irritation from cantharides or turpentine. Other corroborative examples readily come to mind, and the truism is merely cited as an anticipatory substantiation of the postulate to be presented. The parts played by the toxins which have their origin in the secluded pockets in pyorrhea alveolaris and the elusive tonsillar crypts in the etiology of arthritis, neuritis, etc., have lately been so extensively exploited that a review of them here would be supererogatory, and reference is made thereto only in collateral confirmation of the concept which inspired the writing of this paper. Reflection on the foregoing commonly accepted knowledge excites astonishment that analogous excretory irritations encountered in patients not having ingested any material which might precipitate such symptoms

should so persistently have been classed as primary maladies. When, for example, percolation of end-products from some remotely situated pathological process occurs within the nose, we may have a clinical picture of coryza similar to that excited by chilling of the surface, or by bacterial invasion. As no nose is sterile, a culture will almost certainly reveal a "mixed infection." But we are not justified in reasoning post hoc, ergo propter hoc. The mere presence of this or that infective agency does not authenticate that it is the instigator of the then present activity. Bacterial guests may simply be neighbors who "dropped in" without being implicated in the disturbance. Hypothetically, the nasal mucous membrane might be assumed to be a sort of safety valve, serving as an indicator of some internal bullition, and in the present discussion consideration will be limited to derangement of nasal functions conjecturally due to incontiguous tubercular sources. Generically speaking, it may be conceded that a secretion is a substance which is of further use to the economy, whereas an excretion is but eliminated débris. Accordantly, the normal moisture investing the nasal mucous membrane may be considered a secretion, because it undoubtedly has efficacy.

When the excretory functions are ordinarily performed, no inconvenience is experienced, but when adventitious elements must be disposed of there may be afflictive harassment at the area of emergence. Sometimes the burden becomes too onerous, yet excites no particular irritation and vicarious elimination is essayed. Such elimination may be superposed upon a secretory surface. For example, it is familiar that the kidneys expel iodine to a certain degree. When their capacity is taxed, the burden of eliminating the surplusage, or at least chemical products of such surplusage, is allotted to the Schneiderian membrane with coincident distressing hydrorrhea. It is a familiar observation that the arytenoids become unduly tumid during the progress of some cases of pulmonary or laryngeal tuberculosis, but the contingence that a sustained coryza might portend a possible concealed tuberculous nidus appears to have been largely disregarded. A unique physiognomy characterizes the victims of early covert tuberculous invasion. In a minor degree there is resemblance to the facies of hay-fever, yet the lacrymation characteristic of that distressing ailment is not present. On the contrary, one often notes a lactescent tint of the sclera, suggestive of low percentage of hemaglobin. The skin of the upper lip and about the angles of the mouth sometimes assumes a faint purplish tint analogous to that observed in some women during the early months of pregnancy. While only similar in type, and less in degree, that comparison conveys a more graphic conception than a lengthy description might. A peculiar psychological propensity is often noted. The patient aims to minimize the defective resonance due to tumescence of the nasal mucous membrane, and develops a habit of gently and rather surreptitiously mopping the moisture from the nose with the kerchief.

It is improbable that any considerable quantity of toxic material is poured into the blood or lymph streams during the early invasive or the latent tuberculous stage. Yet during such periods one encounters the peculiar coryza alluded to. It appears plausible that such toxic products as are formed have a predilection to escape from the body by way of the nasal mucous membrane, and that the secreting surface smarts under the unaccustomed burden.

Of course, these traits are often encountered in flagrant cases of tuberculosis, but are then usually so overshadowed by more salient signs that their import becomes insignificant and negligible. Sometimes the focal center of infection is ensconced in such manner or place as to exact an exhaustive search on the part of the physician. Painstaking indagation of the thoracic organs may at first fail to elicit any evidence of tuberculous involvement there, yet, in heedless or neglected patients, in process of time unmistakable indications of the bacillary invasion will crop out. One may feel comparatively safe in assuming that in the majority of cases a circle whose radius extends three inches from the thyroid notch will encompass the focal area of the tuberculous infective process giving rise to the nasal outburst. Waldeyer's ring, comprising a circle of lymphoid tissue beginning at the lingual tonsil, and in its upward passage following the course of the posterior pillar, and traversing the small lymphoid mass sometimes called the tubular tonsil, then the pharyngeal tonsil via Rosenmueller's fossa, and thence in reverse order down the other side to the opposite lingual tonsil, is a fertile field for tuberculous processes. Whether borne there by the blood current or deposited there by the respiratory perflation may not be determinable, but the clinical features are uniform. The patients are relatively healthy. Their cardinal complaint is the discomfort brought about by the hyperplasia of the lymphoid tissue comprised in Waldeyer's ring. Children so afflicted are commonly considered "scrofulous." Small tonsils, which are secluded between the anterior and posterior pharyngeal pillars, are sometimes so elusive that only a most painstaking search will prove them accomplices in the pathological process.

A patient's statement that "the tonsils have been removed" should not be accepted without challenge. There may be remnants whose undestroyed crypts constitute serviceable propagation depots. Deep palpation along the sides of the neck will probably reveal strings of very small glands, some of them quite sensitive, merged in the cervical fascia. The engorgement of the glands is presumably due to the absorption of products sent forth by the bacilli which have lodgment at one or several points in the lymphoid tissue constituting Waldeyer's ring. The characterizing, unyielding coryza preponderates to such degree that other symptoms appear subordinate and minor signs may be overlooked. Taking all these matters into consideration, they would seem to warrant the hypothesis that intractable excretory irritation of the nasal mucous membrane presents strong presumptive evidence of some tuberculous activation.

The gratifying results attained by judicious treatment of early tuberculosis are too familiar, and the methods of ministration are so well grounded that their recital here appears uncalled-for.

Highland Building.

Cure or Arrest of Hydrocephalus.—Eunika relates the case of a child aged 14 months which sustained a fall from which there followed perforation of a hydrocephalus with bulky effusion under the skin. As a result of three punctures from 500 to 700 cm. of this effusion were drawn off and the balance was absorbed. The disease, if not cured, was at least arrested.—*Zentralblatt für Chirurgie.*

DEEP BREATHING.

SINCE deep breathing is a popular health measure, advocated also by many physicians, a scientific consideration of the subject by a competent medical observer should be welcome. In the *Berliner klinische Wochenschrift* for October 2, Professor Arnold Hiller writes on the action of deep breathing on certain important somatic functions. The author gives a résumé of the scientific literature of the subject since 1890. Deep breathing has been recommended chiefly for asthmatics and young candidates for tuberculosis, especially children. Aside from these uses the exercises are employed to promote euphoria and efficiency. In 1890 the author was recommending sea bathing because it was naturally calculated to ventilate the lungs through the combination of high atmospheric pressure and the sea breezes. The first component to receive his attention was diaphragmatic breathing, which in superficial breathers is the only form in use. As the diaphragm descends with forced inspiration it compresses the soft, plastic tissue of the liver and increases the passage of blood through that organ. At the same time it increases the secretion and excretion of bile. Any condition like gallstone disease which is aggravated by stagnation in the liver may in theory be prevented by deep diaphragmatic breathing. The stomach, when filled with food, may likewise be favorably influenced by the same factor; because the movement of the stomach-contents through the pylorus is facilitated. The influence exerted on other abdominal viscera, such as the spleen and kidneys, is problematical.

Costal breathing is concerned chiefly with the upper portion of the chest and promotes the circulation of blood in the lungs and heart, because as the chest expands the blood in the great veins is forced toward the heart; while at the same time the circulation of the brain is somewhat depleted when for any reason that organ is congested. Under favorable conditions a deep inspiration with expansion of the chest may be seen to empty the distended veins on the backs of the hands. As similar conservative action may be demonstrated in cases of varicose veins and hemorrhoids. So far as any alleged danger of emphysema of the lungs is concerned, the author has seen the latter condition disappear under deep breathing. To return to the heart the author insists that deep breathing causes a physiological hypertrophy of the right side, in which the musculature is apt to be relatively weak.

The subject of the respiratory exchanges, which naturally is one of vast importance, is left by the author to the last. An increased intake of oxygen naturally stimulates metabolism. Increased combustion of carbohydrates may cause a notable reduction in weight, while all products of incomplete catabolism become fully oxidized. Deep breathing is therefore the most scientific resource for the prevention of uric acid disease. Much depends upon a correct technique. One must begin with diaphragmatic breathing, which naturally precedes rib breathing. The inspiratory movements are now slowly increased until all the muscles involved in rib breathing gradually participate. One begins with three daily periods of 15 or 20 minutes each. The position of the breather is immaterial, and he may do his forced breathing while standing or walking. The author makes one assertion which should be modified slightly. It is true that continuous deep breathing will cause an increase in the volume of the radial pulse, but in some individuals a very deep breath appears to arrest the pulse because of the compression of the subclavian artery by the fully inflated apex of the lung. Hence inspirations should be limited to a certain number per minute.

SUBFEBRILE TEMPERATURE AND FEBRICULA.

SLIGHT hyperthermia may represent the initial phase of a serious process; of a benign type of a disease which usually pursues a serious course; or of a condition essentially mild. Fifty years ago the term "slow fever" was used for a protracted febricula, but such terms disappeared with the general use of the clinical thermometer. If the latter instrument were in more familiar use we should doubtless find that many an individual who is feeling below par is running a subfebrile evening temperature. If the medical man recognizes such a case he orders the patient to bed until the temperature becomes normal. But when, as is often the case, rest does not help and the patient rebels at the rest cure, the practitioner is constrained to let the patient go about his business, and the temperature becomes normal in time. Febricula is most common in childhood, when many affections react with subfebrile temperature, or actual fever. This may be associated with slight colds, gastrointestinal disturbances, a single inflamed tonsillar crypt, etc. In adults the same conditions may or may not cause febricula.

In *La Riforma Medica* for September 18, Professor Rossi considers a number of conditions which cause mild hyperthemia of a sustained type. The first patient suffered from Graves's disease. The symptoms were numerous but very vague, and at first no diagnosis was made. A subfebrile temperature at times became febrile. The entire range was 37° to 38° C. (98.6° to 100.4° Fahr.). Lowering of temperature had no prognostic significance. The theory in such cases is that hyperthyroidism can affect the heat centers. In another case a febricula

was brought with difficulty into relationship with lues. In an elderly man with a slight febrile movement pointing to an enterocolitis the cause was found to be pseudoleucemia. In certain cases of cancer and sarcoma, usually of the viscera, rise of temperature may be present. The febricula of tuberculosis requires no discussion. A temperature up to 100° Fahr. in a child of 4 years was found to have been due to basilar meningitis.

There are, however, quite different types of febricula. Rossi mentions the case of a woman who was sent to a sanatorium for general failure of health. A subfebrile temperature led to the diagnosis of tuberculosis, which was, however, negatived by other tests. No cause could be found for the temperature rise nor for the general state. Subsequent developments appeared to show that all the symptoms were psychogenic. Rossi also gives in great detail other cases which were finally found to be examples of nervous or hysterical hyperthemia. For all of these cases he makes use of the term dysthermia—whether neurotic or endocrinic or mixed origin. There is no doubt that this neuro-endocrinic mechanism may be sometimes involved in the first-mentioned cases of febricula—notably in cases of exophthalmic goiter.

THE FRENCH TREATMENT OF BURNS.

THE daily press and certain medical reports from the European fighting front have frequently mentioned a new and successful treatment of burns by French surgeons. Since the special dressing was known by a coined word and since its composition was not definitely stated, the profession has been awaiting an official description. In the first place it is not very new, since its employment goes back to 1904. It has been in use in the present war almost from the outset, but has only recently come into anything like general employment. It consists of a mixture of paraffin and resin, and while no chemical change is set up it possesses peculiar physical properties which make it available for the treatment of burns.

In the *Archives de médecine et de pharmacie militaires* for August Dr. Barthe de Sanfort reported over 300 burns in soldiers treated with the remedy, which is described in detail. The name "ambrine," with which it was christened, comes from its amber hue, and seems to be purely descriptive. This surgeon states that he first devised the formula in 1904. Toussaint used it in 1907 in the Military Hospital at Lille, while another colleague, Michaux, has also had long experience with it. Recently Kirmisson presented some patients before the Société de Chirurgie in which the remarkably favorable action was well demonstrated.

The substance is a solid which fuses at about 50° C. and may be sterilized by boiling without injury. It is applied hot (at 70° C.—158° F.), causing no pain whatever, and even after 24 hours is still warmer than the body. The favorable action is due in part to local hyperthermia. Occurring as it does in cakes of paraffin consistency it is broken up into bits of various size, heated to 125° C. (257° F.) and then cooled to 70° C. (158° F.), the temperature of application. Its use is not confined to burns for it is excellent in freezes and is even superior in the treatment of certain wounds. It is first applied in very small quantities with formation of a thin pellicle. Over this is placed a very thin layer of cotton, which is followed by more of the remedy. This simple dressing is painless and inexpensive. It is removed in 24 hours and comes away *en masse* and without pain. It is true that considerable pus, often of foul odor, is found beneath. This, together with loose sloughs, is carefully wiped off and the surface dried with a hot air douche. The dressing is then reapplied. In no type of burn is it contraindicated. In general, rapid healing takes place with superior end results.

LEAD POISONING FROM IMBEDDED BULLETS.

INTEREST in this possibility has been revived during the present war. Nothing seems more assured than that bullets in the tissues do not, in the vast majority of cases, cause even the mildest form of plumbism. The question is, have they ever caused this condition beyond doubt. Lewin and Küster long ago answered this question in the affirmative and in more recent years Dennig and also Neu have analyzed a very large number of observations and have found the sequence less uncommon than one might otherwise believe. It is necessary to follow cases up, because plumbism may not appear until many years after the injury. At a session last June of the Verein der Aerzte in Halle a. S. (*Muenchener medizinische Wochenschrift*, September 26) Disselhorst discusses the possibility of the solubility of metallic lead in the tissues and the mode of its elimination. That erythrocytes show basophile granulations as a result of lead absorption cannot always be shown. Should the bullets be extracted as a prophylactic or curative measure? For anatomical reasons this must be answered largely in the negative—for we are presumably dealing with deeply buried projectiles. In discussion Schneider said that he had seen plumbism follow retention of bullets; why it does not always occur is a great mystery. Deeply seated bullets must not be removed as long as these are reactionless. Should lead appear in the urine the question of removal must be thought of, all depending on the general surgical problems involved. David thought the blood test most dependable if several tests were made before reaching a decision.

THE ENGLISH BULLDOG.

THERE are certain characteristics, said to be national, which we are fond of exemplifying by anecdotes. Some of these are complimentary, many the reverse. Thus we speak of the pugnacity of the Irish, the economy of the Scot, the vivacity of the Frenchman, and the gallantry of the Spaniard. The English nation takes a secret satisfaction in the tradition which ascribes to her children the quality of bulldog perseverance, the not-knowing-when-you're-beaten spirit, the tenacity which "muddles through" somehow. The soldier imbued with such a spirit would, theoretically at least, be hard to kill, and a communication to a recent number of the *Lancet* seems to bear this out. Dr. Sidney D. Rhind writes in the issue of September 9 of a British soldier who accidentally received two bayonet wounds in the chest while practising with another soldier. When seen, shortly afterward, he was

found to have a left-sided pneumothorax with internal hemorrhage. About four inches of colon and mesentery were protruding from one of the wounds. He was operated on under a general anesthetic and the abdomen was examined, but no injury to any viscus was found. The operation lasted half an hour, and he survived it six and a half hours; but the remarkable part of the affair was that a post-mortem revealed that one of the wounds had gone through the diaphragm into the right ventricle, injuring the septal cusp of the tricuspid valve, and then through the right auricle. Each of these two wounds in the heart would admit an index finger easily. This man, in other words, lived eight and a half hours with two large wounds of the heart, a hemopneumothorax on one side and a hemothorax on the other. And during these eight and a half hours he underwent an abdominal section under general anesthesia. No wonder the British don't know when they are beaten. They do not even know when they have been instantly killed.

News of the Week.

Plan New State Hospital.—At the first hearing before Governor Whitman on the New York State budget, on December 19, Dr. George W. Pilgrim, medical superintendent of the State Hospital Board, called attention to the fact that during the past fifteen years no new State hospital has been built, although in that time the insane population in the various hospitals has increased from 20,845 to 35,657. Dr. Pilgrim told the Governor that the Board planned to build a new institution on State land to care for a population of 1,500, and to change the district boundaries so that the metropolitan district will be relieved by the transfer of 1,500 patients from Ward's Island to Poughkeepsie.

Ambulance in Collision.—A motor ambulance of St. Joseph's Hospital, Paterson, N. J., was in collision with an Erie Railroad train on December 22, and was completely demolished. The driver was thrown out, and so badly injured that his death was expected; the surgeon and the patient, a woman being taken into the maternity ward of the hospital, however, suffered only minor injuries.

Hospital Shelled.—The Italian War Office, on December 22, announced that the military hospital in Goritz had again been shelled, in spite of its protection by visible red crosses. Of the sanitary personnel, two were killed and four wounded.

Herter Lectures.—The Faculty of the University and Bellevue Hospital Medical College announces that five lectures will be given under the Herter Foundation on "The Distribution of Inorganic Compounds in Animal and Vegetable Tissues, and the Forces that Determine It," by Prof. A. B. Macallum of the University of Toronto. The first lecture will be given on Monday, January 8, 1917, at four o'clock, at the Carnegie Laboratory, 338 East Twenty-sixth Street, and the remainder of the series will be given on subsequent days at the same time and place.

New Hospital Building.—The directors of the Manhattan Eye, Ear and Throat Hospital announce that there will shortly be constructed a six-story stone extension to the present hospital building on East Sixty-fourth Street, to cost $350,000, and to be used as a nurses' home and administrative building.

Gifts to Charities.—By the will of the late Jacob H. Purdy of New York, the sum of $100,000 is bequeathed to St. Mary's Free Hospital for Children of this city, for the establishment of free beds in memory of the testator's sister, Joanna H. Purdy, formerly a member of St. Mary's Guild.

Dr. J. Madison Taylor of Philadelphia addressed the College of Physicians, Pittsburgh, on the evening of December 14, on the subject, "The Scope of Reconstructive Therapeutics."

Physicians Graduate.—Forty-seven candidates successfully passed the recent examinations of the Medical Department of the University of Toronto, and all have enlisted for service overseas. The class had been at work steadily for the past fourteen months in order that they might be ready for service as soon as possible, and a special convocation for the conferring of degrees was held on December 11.

Care of Infantile Paralysis Cases.—The New York Committee on After Care of Infantile Paralysis cases, which grew out of a series of conferences called by Health Commissioner Emerson, and includes about 350 persons representing the medical profession, hospitals and dispensaries, nursing associations, charitable societies, and the general citizenship, has undertaken three major pieces of work. First, it has tried to coordinate the efforts that have been made for the treatment, home care, and training of children left paralyzed by the epidemic, to distribute them among the agencies, and to keep track of them so that none shall be neglected. Second, it has attempted to unite the several transportation funds and to augment them, so that, if possible, all children in need of special transportation to and from dispensaries may have it; to which end a Committee on Transportation has been appointed. And third, the committee has undertaken to raise $250,000 for the work. This last branch of the work has been entrusted to a Committee on Appeals, the administrative expenses of which will be met by the Rockefeller Foundation, so that contributions to the funds will be used entirely for the after-care work. All of this work is being carried on with the cooperation of the Department of Health and of the Department of Public Charities. Up to December 12, the committee reports, 5,773 children had been referred to it by the Health Department, and 5,504 were under treatment or had been satisfactorily accounted for; 51 had died since their discharge from quarantine; 30 had left the city; and 152 had not been found. To the same date, the Committee on Transportation had been able to provide seven motor buses and four motor cars, which had been fully engaged in transporting 1,227 different children a week. About $2,000 had been spent by the committee for braces, upon request from the dispensaries, and the Health Commissioner has turned over to it the large fund for braces raised in answer to his appeal last summer.

Birth Control Advocates Defeated.—At a meeting of the Medical Society of the County of New York on Tuesday evening of this week, a resolution asking for the repeal of the State law forbidding instruction in measures for preventing conception was defeated by a vote of 210 to 72.

Medical Society Elections.—DUVAL COUNTY (FLA.) MEDICAL SOCIETY: Annual meeting at Jacksonville on December 6. Officers elected: *President*, Dr. William MacDonell, Jacksonville; *Vice-President*, Dr. Kirby Smith; *Secretary-Treasurer*, Dr. S. Richardson.

ORLEANS PARISH (LA.) MEDICAL SOCIETY: Annual meeting at New Orleans on December 9. Officers elected: *President*, Dr. Paul J. Gelpi; *Vice-Presi-*

dents, Dr. Frank J. Chalaron, Dr. J. George Dempsey, and Dr. H. E. Bernadas; *Secretary*, Dr. Charles A. Bahn; *Treasurer*, Dr. H. W. E. Walther, all of New Orleans.

Greene County (Mo.) Medical Society: Annual meeting at Springfield on December 12. Officers elected: *President*, Dr. William Reinhoff; *Vice-President*, Dr. John C. Matthews; *Secretary*, Dr. T. O. Klingner; *Treasurer*, Dr. Edwin F. James, all of Springfield.

Medical and Surgical Association of the Southwest: Third annual convention at Frankfort, Ky., on December 11. Officers elected: *President*, Dr. J. I. Butler, Tucson, Ariz.; *Vice-Presidents*, Dr. R. E. McBride, Las Cruces, N. M., and Dr. J. W. Laws, Lincoln, N. M.; *Secretary-Treasurer*, Dr. D. W. Detwiler, El Paso, Tex.

Harrison County (Ia.) Medical Society: Annual meeting at Logan on December 7. Officers elected: *President*, Dr. Charles S. Kennedy, Logan; *Vice-President*, Dr. A. H. Konigmacher, Missouri Valley; *Secretary-Treasurer*, Dr. J. D. Slattery, Dunlap.

Grafton County (N. H.) Medical Society: Annual meeting at Woodsville on December 13. Officers elected: *President*, Dr. Percy Bartlett, Hanover; *Vice-President*, Dr. A. T. Downing, Littleton; *Secretary-Treasurer*, Dr. John M. Wise, Glencliffe.

Pittsburg County (Okla.) Medical Society: Annual meeting at McAlester on December 8. Officers elected: *President*, Dr. J. O. Grubbs, McAlester; *Vice-President*, Dr. George S. Turner, Krebs; *Secretary-Treasurer*, Dr. James C. Johnston, McAlester.

Columbia (S. C.) Medical Society: Annual meeting at Columbia on December 11. Officers elected: *President*, Dr. Le Grand Guerry; *Vice-President*, Dr. John La Bruce Ward; *Secretary-Treasurer*, Dr. Edythe Welbourne.

Obituary Notes.—Dr. Nora Johnson Ross of Chicago, Ill., a graduate of the Chicago College of Medicine and Surgery in 1911, died at her home on December 1, from septicemia, aged 47 years.

Dr. William Calvin James of Lawson, Mo., a graduate of the College of Physicians and Surgeons, Keokuk, Iowa, in 1864, died at his home on November 12, aged 75 years.

Dr. Ira Sidney Hooker of Winner, S. D., a graduate of the College of Medicine of the State University of Iowa, Iowa City, in 1903, died at the South Dakota State Hospital, Yankton, on October 25, aged 40 years.

Dr. Albert A. Dougherty of Muscoda, Wis., a graduate of Starling Medical College, Columbus, Ohio, in 1896, died at his home on November 23 from angina pectoris, aged 51 years.

Dr. Jabez Fisher of Fitchburg, Mass., a graduate of the Medical School of Harvard University, Boston, in 1850, died at his home on December 15, aged 92 years.

Dr. Harry Malcolm Wasley of Shenandoah, Pa., a graduate of the Medico-Chirurgical College of Philadelphia, Pa., in 1900, and a member of the Medical Society of the State of Pennsylvania and the Schuylkill County Medical Society, died suddenly on November 28, from heart disease, aged 43 years.

Dr. Francis Harvey Roof of New York, a graduate of the College of Physicians and Surgeons, Columbia University, New York, in 1862, died on December 14, aged 76 years.

Dr. William Overholt Baker of Louisville, Ohio, a graduate of the University of Wooster, Medical Department, Cleveland, Ohio, in 1873, died in the Ingleside Hospital, Canton, Ohio, on November 26, from broncho-pneumonia, aged 89 years.

Dr. Charles Young Hogsett of Fort Worth, Tex,. a graduate of the Department of Medicine of the University of Virginia, Charlottesville, in 1895, and a member of the American Medical Association, the State Medical Association of Texas and the Tarrant County Medical Society, died in a sanatorium in Saratoga Springs, N. Y., on November 25, aged 44 years.

Dr. John C. Crowell of Pawpaw, Ill., a graduate of Rush Medical College, Chicago, in 1891, died at his home on November 17, from cerebral hemorrhage, aged 58 years.

Dr. Moses S. Brundage of Rockford, Ill., a graduate of Rush Medical College, Chicago, in 1883, died in his office on November 19, from heart disease, aged 58 years.

Obituary.

WALLACE WOOD, M.D.

NEW YORK.

Dr. Wallace Wood of New York, for many years the holder of the Samuel F. Morse chair of art in New York University, died after a short illness from pneumonia, in Bellevue Hospital, on December 17, aged 64 years. Dr. Wood was educated abroad and had achieved an unusual reputation in several lines of research. He had written largely on many subjects, varying from "Twenty Styles of Architecture," to "A New Method in Brain Study," and had formed a remarkable collection of pictures, costumes, and relics illustrating the history of civilization, which is now in the possession of New York University.

Correspondence.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

AT THE ROENTGEN SOCIETY—PAROXYSMAL COUGH—IRISH MEDICAL GRADUATES—CEREBROSPINAL MENINGITIS—RESIDENTIAL TREATMENT OF TUBERCULOSIS.

London, Dec. 2, 1916.

At the Roentgen Society, Captain C. Thurston Holland, the new president, remarked in his address that during the war mistakes had occurred both in interpretation and in localization in consequence of *x*-ray work having been entrusted to unskilled and untrained operators. This work should be carried out by medically qualified persons with special experience in pathology, as well as in physics, electricity and *x*-ray work. Dissatisfaction was expressed by the president with the present position of radiology, and particularly with the installations in the smaller hospitals of districts where only the services of untrained operators could be obtained. The value of such services was very variable, and in some instances could not be said to exist, and might be more than replaced by error. Electrotherapeutics is becoming more and more important, and should not be separated from other modes of treatment. The time for separate radium institutes has gone by, and the recognition of radiology and electrotherapy by the universities and schools should no longer be delayed. I understand that on your side such teaching is well organized, so that you are, as usual, ahead of us.

Paroxysmal cough is often the chief trouble in connection with influenza, or, indeed, any form of catarrh. In every case the fauces should be explored at the outset and the mucous surface will almost always deserve attention. Inflammation in some stage will generally be present, and swelling of the tissues will be the most marked appearance. The tonsils will present this symptom most prominently, but that should not be allowed to obscure other changes in the lining membrane. If the tonsil is so enlarged as to come from time to time in contact with the epiglottis, this may set up severe attacks of spasmodic cough. The local application of trichloracetic acid is the best remedy. With a holder bent at a right angle and charged with a very thin layer of cotton wool moistened with the acid, it is easily applied to the swollen tonsil and restricted to that. Mr. Hovell reported two very chronic cases to the Section of Laryngology (R. S. M.), one of which had lasted for 15 years, the other for 7. In both of them the cough diminished concurrently with decrease of the swelling of the tonsils. To some extent he approves the old popular remedy of garlic, which has long been held in the highest repute by herbalists, who use it by peeling the "cloves" (segments of the root), cut into thin slices, and worn beneath the soles of the feet, between two pairs of socks If worn next to the skin too great irritation will be set up. He mentions two cases of persistent cough following attacks of pertussis, in both of which relief was obtained as the swelling of the tonsil diminished under treatment by trichloracetic acid. Considering the paroxysms of whooping cough as the result of enlarged tonsils, he holds its terrors as no longer existing, since the juice of garlic passed into the circulation through the skin at once destroys the microorganism, after which a strong astringent applied to the swollen tonsil will complete the cure. Care should be taken to prevent the fluid entering the larynx. This sometimes has occurred, and the spasm so set up is distressing. To arrest it, the patient should be induced to speak. The pronunciation of a single syllable will often suffice.

The Irish Medical Graduates' Association has presented an address of congratulation to Dr. Macnaughton Jones, who has lately celebrated his golden wedding, and who has been the chief worker at the helm of the society for the last 37 years, has been president three times, and has presented it with beautiful works of art which ornament its festive board.

Dr. Macnaughton Jones, in thanking the members, said he would treasure it as one of his most valued heirlooms, as coming from those whom he recognized as worthy successors in the footsteps of the men who, when he joined the association in 1879, presented a galaxy of talent of which they were all proud. He was further delighted that it was not only in professional skill they were worthy successors of the giants of those days, but in devotion to the cause for which all our countrymen are fighting.

In the three months ending on September 30 there were 66 cases of cerebrospinal meningitis notified in London, with 36 deaths. Last year, in the corresponding period, there were 102 notified, with 62 deaths.

At the end of September, this year, 446 persons were undergoing residential treatment for tuberculosis provided by the London County Council. Of these, 136 were adults and 310 children.

CANADIAN LETTER

(From Our Special Correspondent.)

FEEBLE-MINDED IN ONTARIO—A FOOD DICTATOR IN TORONTO—RAILWAY ARRANGEMENTS FOR CONVEYING SICK AND WOUNDED SOLDIERS—MEETING OF THE CANADIAN MEDICAL ASSOCIATION—MEETING OF THE ONTARIO MEDICAL ASSOCIATION—RETURN OF COLONEL NASMITH—APPOINTMENT OF CAPTAIN ELLIS IN HIS PLACE—RETURN OF DR. G. ADAM—RESIGNATION OF C. R. CLARKE AS SUPERINTENDENT OF TORONTO GENERAL HOSPITAL—APPOINTMENT OF PROFESSOR MACALLUM AS HEAD OF THE COMMITTEE FOR INDUSTRIAL AND SCIENTIFIC RESEARCH—CAPT. A. H. CAULFIELD DIRECTOR OF TREATMENT OF TYPHOID FEVER AND CEREBROSPINAL MENINGITIS AT SHOMCLIFFE MILITARY HOSPITAL—LIEUT.-COL. T. B. RICHARDSON MADE PRESIDENT OF THE MILITARY BOARD OF TORONTO—LIEUT.-COL. CLARENCE STARR AT THE ORTHOPEDIC HOSPITAL AT RAMSGATE, ENGLAND.

Toronto, Dec. 21, 1916.

The problem of the feeble-minded is a grave one in all parts of the world, graver in the old world especially, because industrialism, urban life, and conditions of living generally tend to the deterioration of the race. However, on this side of the Atlantic we have our feeble-minded, like our poor, always with us, and recently, both in the United States and in Canada, the proportion of defectives to the general population has increased considerably. This is due to several causes: to the tendency to massing together of the population in cities, to the increase of industrialism, but perhaps above all to the widespread prevalence of social disease, and especially of syphilis. In addition, Canada has received for some years a somewhat large number of defectives from Europe. An important meeting to discuss the situation as regards the mentally defective persons in the population of Toronto and of the Province of Ontario was held by the Section of State Medicine of the Toronto Academy of Medicine a short time ago.

Dr. C. R. Clarke, superintendent of the Toronto General Hospital, one of the speakers, stated that the reason why Ontario possessed such a large mentally defective population was because politicians had failed to do their duty in preventing hordes of defectives from coming into the country. He stated that 54 per cent. of the defectives examined at the psychiatric clinic at the Toronto General Hospital had been imported, and many of them had been in the country only a short time.

Dr. C. M. Hincke, connected with the psychiatric clinic at the Toronto General Hospital, said that there had been examined in that clinic 285 feeble-minded individuals who were habitual thieves, and who were still at large in Toronto. Fifty-eight feeble-minded persons had been examined whose greatest delight was to burn down buildings. One hundred and twenty feeble-minded persons examined had attempted to commit murder. Perhaps the chief menace of uncontrolled mental defectives is that they propagate their species in a most prolific manner, and the uncontrolled female mental defective is a constant source of danger to the race and the state, in that she is the main agent in spreading that most destructive of diseases, syphilis. At least 60 per cent. of prostitutes are feeble-minded. Another mode in which the mentally defective impede the wheels of progress is that when educated with normal children they are

apt to convey and spread their taint, and they hinder the education of all.

So far as Ontario was concerned, Dr. Helen McMurchy stated that there were 7,000 feeble-minded persons in Ontario, while Dr. C. M. Hincke was of the opinion that there were 3,000 in Toronto alone.

The object of the meeting was to impress upon the minds of the medical profession and the general public the gravity of the situation and to suggest and discuss the most effectual means of successfully coping with the existing state of affairs.

The suggestion brought forward by the Toronto branch of the Provincial Association for the Care of the Feeble-minded was told by Dr. Conboy. It is proposed to establish industrial farm colonies for mentally defective boys and girls, such institutions to be of the cottage type, with accommodations for 500 inmates in each institution, in buildings each capable of accommodating fifty.

After discussing the matter for more than two hours and a half the Toronto City Council, on Dec. 18, decided to apply to the Ontario Legislature for permissive legislation to the following effect: 1. To permit the city to issue debentures without the consent of the ratepayers, not to exceed $150,000, for the erection of buildings and equipment for the care of the feeble-minded; and 2. To amend the industrial Farms Act to allow the use of such portions of the industrial farm lands for a site as may be hereafter determined.

The high cost of living, which is attributed by producers and retailers to the war, is pressing heavily upon a considerable part of the population of Canada. Those workers who are engaged in munition making, or in other employments concerned in war supplies, do not feel the advanced prices of all commodities, for the reason that they are earning more money than they ever earned in their lives before. But the poor who have not been afforded the opportunity to earn money in this manner are suffering seriously from the enhanced cost of the necessaries of life. With an early, sharp winter, and the cost of fuel and food at famine prices, the situation is becoming worse. In Toronto, the city authorities have recognized the fact that something must be done to ameliorate conditions, and with this end in view have appointed Dr. Chas. Hastings the medical officer of health to thoroughly investigate into all the circumstances of the case. Dr. Hastings has been vested with exceptional powers, indeed almost with the powers of a dictator, and there is no doubt that his investigations will be searching and productive of good results. Such a duty obviously is well within the province of a department of health, for few events prejudice health more potently than the high cost of the necessaries of life. If individuals cannot obtain good food in sufficient quantities, it follows that their vitality is decreased and their powers of resistance to disease diminished. Infants and children, especially, suffer from the lack of nourishing food and warmth. It matters little how costly luxuries become, as luxuries are not essential to health and well being, but when the necessaries of life are beyond the reach of the poor man's pocket the question is one which intimately concerns the community at large, as it is a menace to the public health.

When Dr. Hastings has thoroughly probed into the reason for the excessive cost of the necessaries of life he will doubtless suggest measures of relief, and it is to be hoped that he will be given the powers of a dictator to enforce such measures.

Arrangements have been made with the Intercolonial and Canadian Pacific Railways for the provision of hospital trains to bring wounded soldiers from Halifax upon their arrival from England. The trains are being built on the same plane as the British military hospital trains, but adapted to the larger Canadian cars. They will be fitted up with hospital beds, surgeries, and accommodation for medical men and nurses. There are said to be in England about 20,000 wounded Canadians, and it is expected that about 250 will leave for Canada each week.

It has been decided to hold the general meeting of the Canadian Medical Association at Montreal on June 13, 14 and 15, 1907. Dr. A. D. Blackader, acting dean of the Medical Faculty of McGill University, has been unanimously chosen president, and Dr. W. S. Morrow, president of the Montreal Medico-Chirurgical Society, vice-president.

The annual meeting of the Ontario Medical Association will take place in Toronto from May 31 to June 12 next.

Col. E. E. Nasmith, C. M. G., Ph.D., Director of the Health Department Laboratories of Toronto, who had done so much excellent work in the sanitary direction both at the camp at Valcartier and overseas has been relieved from active duty and has returned to Toronto. It was considered that the special work which he had organized was practically completed and that it was now more or less a question of routine administration. However, in spite of the fact, leave was given with a good deal of hesitation and chiefly because Dr. Hastings represented that he was urgently needed in Toronto.

Colonel Nasmith may be said to be to a considerable extent responsible for the success of the precautions that have rendered typhoid and paratyphoid fever negligible quantities in the British armies during the war. Of course, inoculation has played a paramount rôle in warding off an epidemic, but the manner in which the water has been sterilized so effectively by chlorination is due to Colonel Nasmith.

Capt. Arthur Ellis, who has done so much valuable research work at the Rockefeller Institute and afterward in the army, has been appointed to succeed Colonel Nasmith as officer-in-charge of the sanitary arrangements of the Canadian oversea forces at the front. Captain Ellis will be assisted by Capt. George Campbell. Capt. Ellis is a son of Professor Ellis, dean of the faculty of Applied Sciences in the University of Toronto.

Dr. George Adam, Professor of Pathology at McGill University, has been granted leave of absence and has returned to his work in Montreal.

Dr. C. R. Clarke has resigned from the superintendency of the Toronto General Hospital after filling that position for five years. Doctor Macallum, Professor of Physiology at Toronto University, has been appointed head of the Committee for Industrial and Scientific Research. The committee has been formed at the instance of the Federal Government with the view of organizing industry and science on a thorough working basis. The war has aroused the British Empire to the need for more and better organization in all branches of industry and commerce, and, moreover, it is recognized that science plays a great part in such an organization. No more able man for the post of head of the committee could be found in Canada than Professor Macallum.

Capt. A. H. Caulfield, A. C. M. C. for Gravenhurst, Ont., is now directing the treatment of cases of typhoid fever and cerebrospinal meningitis at the Shorncliffe Military Hospital.

Lieut.-Col. Thomas B. Richardson, who has been in command of the Toronto Military Base Hospital, has been appointed president of the Military Board, Toronto, and the temporary command of the base hospital has been given to Lieut.-Col. Cameron A. Warren of Toronto. The laboratories of the hospital have been placed under the direction of Capt. George D. Porter.

Lieut.-Col. Clarence Starr, the well-known Toronto surgeon who has had charge of the military orthopedic work in Canada, is now at the Canadian Orthopedic Hospital at Ramsgate, England. On his return to Canada he will set up similar institutions in this country.

2. Shock at the Front. W. T. Porter.
3. Failing Cardiac Compensation During Pregnancy. Charles H. Lawrence.
4. Some of the Clinical Evidence Relating to the Etiology of Epilepsy, Including Some Notes on the Condition of the Teeth as a Factor in Its Production, and on Its Relation to Alcoholism and to Mental Defect. Hale Powers.

1. The History of the Growth of the Anti-Tuberculosis Movement in Massachusetts and the Lessons to Be Learned Therefrom.—Vincent Y. Bowditch gave an account of the work accomplished in Massachusetts along this line before the Trudeau School of Tuberculosis, Saranac Lake, N. Y. He refers to the early teachings of his father, the late Dr. Henry Ingersoll Bowditch, and his investigations begun in the early fifties as to the causative factors of pulmonary tuberculosis. After eight years of study and research the elder Bowditch presented to the Massachusetts Medical Society a paper under the title "Soil Moisture as a Cause of Consumption." This was in 1862. In 1885 Trudeau founded his famous institution, the first of its kind in America. In 1889, a small farm was purchased in Sharon, Massachusetts, eighteen miles from Boston, and a building erected to accommodate eight women suffering from tuberculosis. This was done in accordance with the theory of the writer that this disease could be cured at a low altitude not far from the sea. In 1891 the Sharon Sanatorium opened its doors as a semi-charitable institution, the first of its kind in New England. Bowditch traced the growth of tuberculosis work all through Massachusetts, as well as in some of the United States possessions, namely, Philippines. He also refers to the types of treatment employed at the present time and concludes with a touching tribute to Edward Livingston Trudeau.

4. Some of the Clinical Evidence Relating to Etiology of Epilepsy, Including Notes on Condition of the Teeth as a Factor in Its Production.—Hale Powers states that the students of epilepsy will for some time be divided into two groups as to the causation of epilepsy: one group holding that it is primarily or entirely a disease of the brain, and the other group who look upon it as an intoxication, probably of intestinal origin. Powers, while holding the latter theory, has not yet been convinced that it is in every case the result of infection by a specific organism, because he has so often seen the arrest of the disease follow the correction of errors in diet and the relief of indigestion and constipation without any treatment designed to remove a supposed infection; on the other hand, he has never seen the arrest of the disease occur when these simple measures have been neglected, even after the removal of the colon, not to mention the persistent use of intestinal antispetics. Several years ago he began to realize the fact that the majority of epileptics had bad teeth, and investigating, concluded that the outcome of a case might depend upon the repairing of the teeth. Notes have been taken by him on the condition of the teeth in fifty consecutive cases, and classifications made according to the conditions of the teeth into "good," "fairly good," "bad," and "very bad." All types of decayed teeth were found, and only the fitness of the teeth to perform their function of chewing has been considered, and the presence of unerupted teeth has not been sought for, because the object of the work has been merely to show that the failure of the teeth to perform their function is a factor in the production of epilepsy. In age the patients ranged from three and a half to sixty years, and include almost all the conditions supposed to produce epilepsy with the probable exception of intracranial tumor. In fully half of the cases the diagnosis was made before they were seen by the writer, and in none has the diagnosis been disputed by others. Of the fifty cases, five have bad teeth, five have fairly good teeth, thirteen have had bad teeth, and twenty-seven have very bad teeth. In one case where there was imbecility and cerebral palsy, digestive troubles preceded the epilepsy, which became less severe under treatment of the digestive condition. Overfeeding, in a mistaken effort to restore the patient's strength, is often the actual cause of an epilepsy following an injury or an illness. Powers cites several cases of epilepsy greatly relieved by careful attention to the care of the teeth and the diet. He says that epilepsy is rare in breast-fed infants, and it does not occur before the age of eighteen months. Other investigations showed that epilepsy in childhood usually begins at the time when the child is beginning to eat solid food that requires chewing, and when the teeth are not sufficiently developed to do the work. Powers insists that epilepsy in children is not the direct result of alcoholism in the parents, when it thus occurs, but is the direct result of neglect and not heredity. There is experimental proof of this in the fact that epilepsy in the children of alcoholic parents is just as amenable to treatment as epilepsy in other children, provided that they can receive proper food and care.

7. Infantile Paralysis Treated with Immune Serum. Orlando H. Petty.
8. Compulsory Health Insurance. Eden V. Delphey.
9. Gastric and Duodenal Ulcers. Samuel Weiss.

3. Aural Complications of Grippe.—Edward B. Dench brings out the facts that aural complications or influenza are severe chiefly from the facts that the constitutional infection lowers the general bodily tone; the hemorrhagic type of inflammation, both in the middle ear and in the mastoid process, occurs probably more frequently as a complication of influenza than other constitutional diseases, and that operative interference in these cases must depend upon the otoscopic appearances and the local symptoms. In other words, the actual local lesion determines the character of the surgical interference.

4. Nose and Throat Sequelæ of Grippe.—William L. Culbert states that each succeeding year brings its own particular type of infectious troubles, usually clas-

sified as grippe; however, nothing new has been shown for the last fifteen years in the manifestations of the disease, according to the literature. It is probable that the specific organism produces a specific effect, modified by the resistance of the victim and the point selected for attack. Stated simply, influenza bacilli generally obtain their first foothold in the nasal mucous membrane, with results already too well known to all. The attack may subside and later flare into flame again in any of the adjacent mucous membranes of the upper respiratory tract, namely, of the accessory sinuses, eustachian tubes, tonsils, ethmoid cells, and may go down into the deeper respiratory tract. There may be no lapse of time in this occurrence, but as it often happens, the acute attack may pass into any of these neighboring membranes. Through Stenson's duct the parotid gland can be involved. Culbert outlines the condition produced more in detail and says that in the preventive treatment of infectious grippe three main points must be considered: (1) The condition of the mucous membrane and the anatomical structure of the nose; (2) the resistance of the subject; (3) the environment, which in our crowded cities is a most important factor.

5. **The Faucial Tonsils in Singers.**—Irving W. Voorhees has made a determined attempt to obtain from over a hundred physicians reports as to the effects they have found were produced by tonsillectomies in singers. From knowledge thus obtained and his own experience he draws the following conclusions: 1. An analysis of 5,000 tonsil operations in singers shows that in the hands of skilled operators there need be no special fear of bad results. 2. It is the consensus that bad results are most often due to cicatricial contractions occurring from careless dissection or from neglected after-treatment. 3. Pain in the tonsillar region, neck, and larynx, is probably due to section of some of the larger branches of the glossopharyngeal nerve (Justus Matthews). 4. Loss of singing voice after tonsillectomy might be due to a nerve lesion, but is probably due to adhesions and cicatricial formations in the fauces. 5. Loss of singing voice occurs very rarely after tonsillectomy. Impaired voice is possible, but most cases show an increased range of from one-half to a full tone. 6. The singer's problem is a very special one and no laryngologist should undertake to operate on these patients unless he has some knowledge of the art of singing. 7. At operation the greatest care and skill must be exercised in securing a clean, free dissection. Injury to the tissues surrounding the tonsil may prove disastrous. 8. Postoperative care is of special importance. The patient should be seen daily until full healing occurs.

9. **Treatment of Acute Alcoholic Delirium.**—Hogan conducted his treatments on patients with delirium tremens last year in the Emergency Hospital Service in San Francisco. He found those of the severer types were suffering from an acid intoxication, so his treatment was directed towards efforts to neutralize and dilute the effects of this intoxication and to favor its rapid elimination. Alcohol, belonging to the group of the hydrocarbon narcotics, has an especially selective action for the fats of the liver and nervous system. The pathological changes produced may be anything from simple edema to severe degenerative changes of the fatty type. Therefore, the treatment, to be of service, must be used in the stage of edema. It was only employed in the most severe cases, and not on the mild drunks or mild delirium cases. He employed a mixture of sodium bromide, sodium chloride, and sodium bicarbonate that could be used in large quantities intravenously without producing the toxic effect of bromide as ordinarily given in large doses. As the severe types also suffer from starvation acidosis, glucose in high concentration was also used intravenously, which in 30 per cent. concentration produced dehydrating effects of the central nervous system. Cases are cited, and from the reports the solution may be given once a day or every two hours, according to the results obtained. It is interesting to note that in the cases given the blood pressure was lowered after the injections. Also any existing edema, as of the brain, will be reduced; all the tissues of the body and the blood are dehydrated by the action of the salts. Both of the solutions are prepared so that they do not produce hemolysis, and the association of the chlorin with the bromin ions prevents the toxic effect of the latter.

12. **A New Treatment for Paralysis Agitans.**—Walter B. Swift offers a set of control exercises for treatment of this condition, and reports that he succeeded in bringing about improvement in a marked case of paralysis agitans which was treated with slow moving exercises taken for fifteen minutes three times a day, and resulted in a general constant relief of bad feelings, occasionally an hour of complete relief from all distressing symptoms, and a quickly gained repose into sleep upon retiring. The treatment, though giving marked relief from intense suffering, even to the point of recovering normal conditions for hours at a time, proves no cure, and the symptoms all returned when the exercises were omitted; but they showed improvement again when resumed, and also again gave relief. Swift reports the case of a woman to whom he gave some vowels to be sounded in a prolonged, steady fashion, to improve the voice tremor. She returned later to relate that the tremor in the hands was better, and that she felt better. He then instructed her to carry out the arm and leg exercises, and in about two weeks she had an hour of complete relief from all symptoms. Improvement became prolonged to satisfaction of patient. The exercises are as follows: Patient stands with all clothing constrictions removed. All motions should be executed slowly. The speed is about 3 feet in ten seconds. All sudden, quick or reflex-like motions should be omitted. Each exercise is repeated three times. The patient should practice from fifteen to thirty minutes, three times a day. Exercises:

1. Right arm up to side; down (shoulder level). 2. Right arm up front; down. 3. Right arm up back; down. 4. Right arm flex; extend. 5. Right hand open; shut. 6-10. Same for left arm. 11-15. Same for both arms together. 16. Right leg up to side; down. 17. Right leg up front; down. 18. Right leg up; back; down. 19. Right leg flex; extend. 20. Toes extend; flex. 21-25. Same for left leg. The form of the exercise may be varied from those given, but the important point is the slowness. One case proves little. A series of cases are now under treatment to be reported later. In one case, at least, the marked temporary relief from severe suffering has amply repaid for all the trouble to do the exercises.

18. The Control of the Nausea and Vomiting of Pregnancy by Intramuscular Injections of Corpus Luteum Extract.—John Cooke Hirst gave a preliminary report on this subject in *The Journal A. M. A.*, February 26, 1916, and now presents the result of further experience. He states that the corpus luteum of pregnancy constantly increases in size until it reaches its acme about the third month; from then on it is gradually absorbed. About this time the vomiting of pregnancy begins, during the period of nonabsorption, and disappears about the time the corpus luteum begins to decrease in size. Hirst considers this to be cause and effect, and works out his theory accordingly. Corpus luteum extract was administered intramuscularly in twenty-five cases, taken as they came, without regard to choice, and the treatment was successful in controlling the nausea and vomiting in twenty-one of the twenty-five. In four it proved a complete failure. Hirst reports the cases of his failures as offering a more interesting field. In the average case of nausea, in which it amounts only to discomfort, and the vomiting is limited to one or two morning attacks, the patient will usually respond to a dose of 1 c.c. every other day for five or six doses. Particularly is this true in the cases in which the nausea has begun to decline. In these cases the effect is almost immediate. In the more severe cases, when nausea is constant, and the patients are subject to frequent paroxysms of vomiting at any time during the day, the dose should be 1 c.c. daily for from twelve to fifteen doses. During the period of treatment the patient's activity should be curtailed, and as much rest as possible is essential. In the pernicious cases 1 c.c. was given twice daily, and more if necessary. These patients are confined to bed, of course. The doses suggested above are average only, and Hirst would not hesitate to give 2 or more cubic centimeters to a dose in severe cases in which a decision as to the value of the method must be reached without delay. The site of the injection is prepared by cleansing with tincture of green soap and alcohol. The deltoid is his preference. The syringe used is glass, and it and the needle are boiled, and allowed to cool before the extract is drawn up from the ampule. Alcohol is not a safe antiseptic to prepare a syringe for injection of any animal extract. The site of the injection is gently massaged for a minute or two after the needle is withdrawn. All injections are given deep, into the muscle, and *never* subcutaneously. The material used is in ampules, containing 1/3 grain of soluble corpus luteum powder in 16 minims of physiological salt solution saturated with chlorbutanol for its anesthetic effect. This amount is equivalent to 2½ grains of dessicated corpora lutea. The preparation is absolutely sterile. Not one of the patients aborted, which is contrary to the accepted theory. A sedative action is also produced in neurasthenic cases. Hirst's results encourage him sufficiently to wish that a more extended trial might be made by the profession to prove that his assertion is not unfounded.

2. An Address on the Medical Profession and the Campaign Against Venereal Disease.—Otto May goes into detail with reference to the final report of the Royal Commission in this important campaign. Broadly speaking, he states that the two chief objects to be attained are education of the general public in the significance of the diseases, their racial and economic effects, the importance of thorough and early treatment, and the dangers of neglect; the provision of wide facilities for the free diagnosis and treatment of the diseases by modern methods. He praises the work done in this respect by the higher-class newspapers of the Kingdom, and condemns the hypocritical attitude assumed by the lower-class papers. Knowledge of the diseases and their effects should be brought to the young, first by educating the parents, who in turn could present this knowledge sensibly to their children; again through the school teachers, and more through the family doctor. Through the Army authorities about 900,000 men in and out of the trenches have been addressed through lectures on this subject. Young women have been taught through lectures by the women doctors. The National Council for Combating Venereal Disease has opened up and controlled many of the above avenues for disseminating such knowledge. The idea of the Royal Commission is the establishment of free diagnosis and treatment through clinics, to be organized and carried on through the borough and county council; 75 per cent. of the cost to be borne by the treasury and 25 per cent. by the local authority. This order is called the "Emergency Order," and is compulsory. The principal requirements demanded of local schemes include: (*a*) Arrangements for enabling any practitioner in the given area to obtain at the cost of the council a report on any material he may submit from a patient suspected to be suffering from venereal disease. (*b*) Provision for the treatment at hospitals or other institutions of persons suffering from venereal disease. (*c*) Provision for the supply, under certain conditions, to medical practitioners of salvarsan or its substitutes. It is suggested that, for any given area, the medical officer of health should, in consultation with the medical staff of the available hospitals and pathological laboratories, organize such a scheme. Cards are to be given to patients both by private practitioners and in clinics, and on these cards prepared by the proper authorities are instructions with regard to the methods of contraction of syphilis and gonorrhea, and the care to be taken by the person having already contracted either disease. May states that Mott has informed him that he agrees with Fournier that in the case of syphilis permission may be given for marriage if four years have elapsed since the primary infection and the patient has been free from all symptoms for at least a year. As regards gonorrhea on the question of marriage Mr. Kidd states that doubtful cases are decided by a bacterial examination of three samples of the contents of the seminal glands, obtained by prostatic

massage. The presence or absence of gonoccoci decide the matter. May touches on "compulsory notification," and gives the reasons for and against it as conditions are at the present time.

4. **Pieces of Clothing Embedded in War Wounds.**—Willan decided after the Jutland naval battle that it would be a good thing if it could be known definitely if there was any foreign body, ordinarily nontransparent to *x*-rays, in the wound; and if the same foreign body could be treated with some antiseptic prior to its entry to the wound, and, if possible, that the same medium should be made to fulfill the two purposes. He found on his wards many cases of septic wounds containing pieces of clothing that were not shown up by *x*-ray. He experimented as follows: Strips of flannelette were dipped in the following solutions, respectively: pot. permanganate, 1:5000; hydrargyrum perchloridum, 1:1000; tinctura benzoin. co.; aqueous solution of borsal (equal parts of salicylic acid and boracic acid); and boracic acid, saturated solution. These strips were dried, laid in a row, and *x*-rayed. The strip soaked in tinct. benzoin. co. showed the densest shadow, while that treated with the borsal was next best in density. As a medium similar to borsal seemed to be the easiest one to work with he decided to experiment with a modification of this. Salicylic acid by itself is not very soluble in water. If, however, borax be added it is readily soluble. The solution used was: ℞ Boracic acid, gr. xv.; salicylic acid, gr. xv.; borax, gr. xxiv.; aq. ad ℥i. This solution is referred to hereafter as "B. S. B." The "B. S. B." solution proved to be impermeable to *x*-rays, was nonirritating to the tissues, contained some antiseptic properties, and was nonirritating to the wearer's skin. This raises the hope for Willan that the soldiers' and sailors' uniforms and clothing could be treated and worn just before battle, with the result of lessening septic conditions in wounds through clothing. Surgeon-General Cheyne adds a note to the effect that he has passed the report of Willan's work on to the Board of Scientific Studies, and hopes some satisfactory conclusion may be reached.

1. **Excision of the Knee Joint as a Method of Treatment for Severe Infections.**—Andrew Fullerton, Consulting Surgeon, British Expeditionary Force, states that the treatment of these wounds of the knee joint produced in warfare has received a good deal of attention of late, and much progress has been made. Colonel Gray and his followers have done much to perfect what may be called the "closed" method. Excision of septic wounds into the joint and removal of foreign bodies, if present, followed by complete suture of the synovial membrane, is now the almost universal practice among British surgeons in France. The results of drainage of the joint by tubes as formerly were disastrous. The results of this old method have been seen during this war. Elder and Fullerton followed several cases of knee joint wounds and found in eleven, in which tubes had been introduced into the joint shortly after injury and before entering their ward, that three of the cases required amputation to save life, five were evacuated to England with total disorganization of the joint and sinuses still discharging, and three gave promise of slight movement. Similar results, or worse, have been common in the experience of other surgeons in France. Fullerton, after comparing the bad results obtained through the use of the tubes, ending in stiff joints, sinuses discharging for months, considers the excision method the one of choice. All obstacles to drainage have been removed, the risk of residual pockets remaining after ankylosis is reduced to a minimum, and it is an advantage with a stiff knee that the leg should be shorter than its fellow of the opposite side, as this allows the foot to swing free of the ground in walking without the toes hitching at every step. In an ordinary case the shortening is just under two inches and part of this can be restored, if necessary, by raising the heel of the boot on the affected side. While it is too early yet to speak of the final results, in the meantime they are concerned in the problem of combating sepsis and saving life. In the area to which Fullerton was attached they have operated on sixty-four knee joint cases according to the method he indorses, namely, excision. It will thus appear that the total mortality was six cases out of a grand total of sixty-four. Two of these followed excision alone, and four occurred after a subsequent amputation. From a study of these statistics, incomplete as they are, one can form a fair estimate of the risks of the operation. It must be remembered that a patient who will not submit to an amputation will, even when the additional risk is explained to him, submit to an operation which gives him a fair prospect of retaining his leg, even with a stiff knee. Fifty cases reached the stage of apparent safety as regards limb and life. Most of these have been evacuated to England, and the remainder are about to be transferred. Those operated on within a few days of the dispatch of this paper are not included, as they are obviously useless for statistical purposes.

2. **Gunshot Injuries to the Knee Joint: Treatment.**—Edmond and Galbraith divide these injuries into two classes: Those which get well without interference; those which are better amputated. Cases do not reach their hospital until forty-eight hours after injury. They have passed through a casualty clearing station, where they are cleaned up and splinted, before being evacuated to the base. The treatment they use is based upon the pathological report of the nature of the fluid in the joint and the *x*-ray. Temperature, pulse, or degree of pain mean little, as they are influenced by the mental condition of the patient, often due to his stress and fatigue. They record the types of wounds and treatment for each, such as aseptic without fracture, where excision is not done unless absolutely necessary. When foreign bodies are present, if small, they are left in, and two drachms of glycerin and formalin are injected and the joint watched. With large foreign bodies present, they are removed through a counter incision and the joint is irrigated with normal saline, the wound sutured, and the glycerin and formalin solution injected. The joint is immobilized on a splint in a position of slight flexion. In the septic cases with fracture the wound is freely excised, detached portions of bone are removed along with the missile, and the track is thoroughly cleansed and scraped. A salt pack is the ideal dressing, provided it comes in contact with all parts, otherwise a continuous eusol irrigation is used. In the acute or moderate cases with sepsis and severe fracture, the treatment amounts to an excision of the joint, but modified, so that the septic nature of the wound can be dealt with by irrigation with 0.5 per cent. eusol. To prevent retraction of the patellar flap they have devised a method of their own. The limb is finally splinted at the proper time in a Thomas

splint, with a ham splint posteriorly to support the knee.

Münchener medizinische Wochenschrift.

October 31, 1916.

Ultraviolet Rays from the Carbon Arc Light in Primary and Secondary Tuberculosis of the Skin and Mucosæ.—Spitzer, the director of the Lupus Sanatorium, Vienna, has been using a modification of the Reyn arc light bath with remarkable results. Cases which failed to improve under other forms of light treatment, as well as *x*-rays and radium, have been cured with this appartus. There is no longer any doubt that chemical rays from this source can exert a deep action. The total number of patients treated has been over 200, and the number of exposures was from 50 to 100, given daily. The amperage was 80 and the voltage 60. The earliest exposures are limited to 15 minutes, increased until at the fourth day they number 60 minutes, at which interval they remain. That lupus of the skin should be benefited is not strange, for that happens when the original Finsen-Reyn lamp is used. Far more impressive is the healing of all tuberculous lesions in the mouth, often in cachectic subjects who are perishing of inanition. Six cases which would have been classed as "inoperable" were readily cured. In several cases initial tuberculosis of the apex incidentally underwent resolution, a phenomenon not fully explained, but perhaps due to the general soborant effects of the light treatment.

Eye Lesions in Nephritis and Eclampsia.—Machwitz and Rosenberg conclude that neuroretinitis albuminuria stands in causal relationship with an injury of the renal function, which leads to azotemia. It is seen but seldom in acute, diffuse glomerulo nephritis, and in about one-half the cases of malignant renal sclerosis, and of chronic diffuse glomerulo-nephritis in the stage of insufficiency. It is, in fact, connected with lesion of the glomeruli. Its absence is of value in differentiating between benign and malignant sclerosis. When present it means that the patient cannot live over two years at the outside. The amaurosis of eclampsia is a part phenomenon of eclamptic uremia, in which the eye grounds are normal save for occasional edema of the papilla. The prognosis is good, and improvement usually follows lumbar puncture. In rare cases true neuroretinitis may coexist. The so-called pseudo-uremic ocular disturbances are seen only in kidney scleroses. As a rule, they are extremely fugacious, and are probably dependent on arteriosclerosis and vascular crisis of the cerebral arteries.

Colloidal Silver in Endocarditis.—Klewitz writes in confirmation of his earlier claims that colloidal silver is of benefit in this condition. There must be some selection of cases, for treatment by the intravenous route cannot come into general vogue because of the fear of untoward colateral effects in unskilled hands. The author regards this attitude as unfounded. The intravenous route is the only one to use, and the technique to be used is all important, as in all intravenous medication. In the treatment of endocarditis the author uses a 2 per cent. solution, 5 c.c. for the initial dose. This is followed by another of 8-10 c.c. As a rule, a chill and temperature rise occur in from 2 to 3 hours after injection. This reaction, although it may be severe, is soon over. Permanent damage has not yet been seen. Unless the reaction sets in the benefit from the remedy may not be noted. If the action of the silver is favorable there will be a lowering of temperature on the following day. There is usually a rise after 2 or 3 days, which indicates a second injection. In most cases more than two injections will be required—enough to cause the permanent disappearance of the fever. In rebellious cases larger and more frequent dosage may be required. Often 3 or 4 injections suffice, while as high as 12 have been required. The severity of these cases is associated with notable valvular lesions. In a small per cent. of cases the remedy disappoints us. At present it is the best, if not the only remedy we possess for endocarditis.

Le Bulletin Médical.

November 18, 1916.

Evolution of the Ureter After Nephrectomy.—Leguen regards this subject as a pertinent one. A woman patient from whom he had removed a tuberculous kidney, three years before, later sought aid for a large uterine fibroma. She had never suffered from the ureteral stump. The fibroma and appendix having been removed, search was made for the ureter through a button hole opening in the peritoneum. It was located near the iliac vessels, and when pulled through the button hole was found to be a fibrous cord. The opening was sutured and the operation completed. A piece of this cord was amputated and examined under the microscope. There was no lumen and no suggestion of tuberculosis. The author then practised ureteral catheterization on a number of nephrectomized patients, with the same result, *i.e.*, the ureter proved impervious in a certain number of cases. He then caused an intensive research to be made, literary and clinical, and found that at first the canal was permeable and contractile for a certain period. To the cystoscope both orifices appeared the same; on the operated side contraction and dilatation occurred, just as if the canal was functioning. This activity persisted for several years, and only very gradually was the mutilated ureter seen to slow up in its contractions. When this point was reached a catheter would no longer pass. This gradual process the author regards as physiological. External fistulæ after nephrectomy seldom occurs, and when present tends to close spontaneously. If this does not occur the entire fistulous tract should be excised. In considerable detail the history of a case of post-nephrectomic ureteritis is given. Pus accumulated and was discharged into the bladder. Resorption fever indicated intervention, and lumbar drainage was established after a very difficult operation, which the author regards now as a technical error. Drainage was sufficient at first, but later proved defective, and retention resulted. As a result of the original ureteritis, a periureteritis had formed, with much thickening. In a similar case the treatment should be extirpation of the entire thickened canal. The patient in question had been nephrectomized for a pyonephrosis, and the ureter had been secondarily infected. Originally it was the custom to take out the ureter along with the kidney. This was the author's custom in 1897-8. The practice was abandoned because the conservative policy seemed to give satisfactory results, the canal being sutured or obliterated by one or another procedure.

La Presse Médicale.

November 16, 1916.

Pathogeny of Cholera.—Sanarelli of Rome has been studying experimental cholera in animals. The old belief is that the vibrio of the disease can traverse the stomach unharmed, and set up the disease in the intestine, but this is certainly not the case in all creatures, for in the rabbit the strongly acid gastric juice destroys the microorganisms readily. It becomes apparent that the route of the vibrio from mouth to intestine is through the general circulation. The point

of election is in the vicinity of the ileocecal valve. This is true not only of the cholera vibrio, but of other intestinal flora, as well, and it is not unlikely that Eberth's bacillus reaches the ileum through the blood. In nursing rabbits the author has caused typical cholera by injecting the vibrio into the tissues and veins, and into a loop of small intestine. Proliferation occurs when the organisms have reached the intestine and the lymphatic absorbents are invaded. If the mother rabbit has been immunized against cholera all experiments on the nurslings give negative results. The presence of intestinal flora, notably the colon bacillus, precipitates and augments the symptoms of cholera, and the colitoxin has the same effect. Otherwise stated, the presence in the intestine of the *B. coli* in large quantities weakens their resistance to the cholera vibrio. But long naturalization of the *B. coli* in the intestine results in some degree of immunity towards injections of this bacillus in the blood. The author's researches in this field have only just begun.

Malignant Infection of War Wounds by Anaerobes.—Lardennois and Baumel emphasize the great role of muscle injury in the genesis of all anaerobic infection. Especially in deep, narrow wounds of muscle is infection of this sort to be feared. There are four different clinical expressions, viz.: local, malignant, tumefaction, and edema, simple local gangrene, localized gaseous gangrene, and diffuse gaseous gangrene. From 77 per cent. to 93 per cent. of these infections are due to shell fragments. The lower extremities are far more frequently involved (78.5 per cent. in the author's cases), and the mortality far higher (95 per cent. in the author's material). In about 25 per cent. the wound was complicated with fracture of the limb. Two germs are responsible for the existence of these infections, viz., the septic vibrio and the *Bacillus perfringens;* but numerous other bacterial flora coexist. In malignant edema there is no blood infection, but simply a toxemia. The gas appears to be due to the digestion of the muscle, including, of course, its glycogen. The term edema is not the same as tumefaction, for the latter occurs in the absence of the former. Simple tumefaction is identical with gas phlegmon, a term which the authors repudiated. The entire muscle may be greatly enlarged from interstitial gas. The infiltration develops rapidly, and is a danger signal. It has been taken for hematoma of the muscle. This condition passes on to gas gangrene, but at the outset little free gas is evident and no odor is present. Edema, when present, is located between the muscles and in the cellular tissue, and may also be associated with bronze erysipelas. The treatment is centered in early incision and removal of all infected tissue.

Correspondenz-Blatt für Schweizer Aerzte.

November 25, 1916.

Swiss Ichthyol.—Merian first discusses the original ichthyol source of the Tyrol. Its native name is rock oil, and aside from the Tyrolean supply this oil occurs in several adjacent regions, including Switzerland—a fact not generally or long known. The author describes minutely the region where the substance is to be found, which is the Tre Fontane, near Meride. Here there are masses of black bituminous slate, in the midst of which are found fossil remains of fishes and saurians. When the entire material is dry distilled a sulphurated mineral oil is obtained. The various species or genera of fishes are readily identified, and include the great fish-lizard, or ichthyosaurus. The oil obtained is brownish, with a slight greenish fluorescence, and contains from 6 per cent. to 7 per cent. of sulphur organically united. The new substance (which is at present marketed as a proprietary with an artificial name) has been tested freely in all suitable conditions and forms of exhibition. It costs only half as much as original ichthyol and its congeners, and has several minor advantages. The author claims that it gives satisfactory results, but does not claim that it is the equal of the ichthyol of commerce. The natural supply seems unlimited, as it is found in the mining galleries and tunnels from which the bituminous slate is obtained. The slate masses alternate regularly with cretaceous dolomitic plates.

Myasthenia Gravis Pseudoparalytica.—Krähenbuhl relates a case of this rare affection. The female patient was 31, and had had several attacks of articular rheumatism, the last at the age of 20. At this period myasthenia gravis first announced itself as diplopia toward evening, with slight ptosis in the left eye. These symptoms improved under treatment, but eight days after hospital discharge they reappeared. She then improved under potassic iodide and began to learn nursing. The following year she began to suffer from progressive sense of fatigue, with leg ache and backache, and later dysphagia and general weakness. The corners of her mouth no longer move when she laughs. She was unable to climb stairs at a single effort, and her knees often buckled under her. She was interned five months, and improved so much under strychnin hypodermics that she was looked on as practically cured. She resumed her domestic life, and remained well for eighteen months. The symptoms reappared, but again yielded to treatment. When 27 she suffered a new recurrence with suffocative attacks. She was now interned and treated with rest, heliotherapy, arsenic, and galvanization. After five months she was much improved, and afterward always favored herself. She became worse, and at this time was first seen by the author. She looked tired, and her lower jaw sagged. There was bilateral ptosis, and she was unable to open her eyes. There was nystagmus and lacrymation. She was unable to wrinkle her forehead or pout her lips, and was hardly equal to raising her upper lip. She had speech defects, and chewing was greatly impaired. Swallowing led quickly to exhaustion, but with rapid recovery. The soft palate hung loose, and fluid food often escaped through the nose. The hands and arms dropped from fatigue after slight use, while the legs were badly involved. She could walk but a few steps, and her gait showed great caution. The myasthenic reaction was positive. This disease has long been known and has been interpreted in various ways. In recent years it has been regarded as a syndrome which occurs in Addison's disease and leukemia, as well as uncomplicated. From another viewpoint it can hardly be distinguished from bulbar paralysis. At present it is best regarded as neurogenic, and some evidence of an anatomical substratum has been found in the nervous system.

El Siglo Médico.

November 18, 1916.

Two Cases of Lathyrism.—Dr. Fernandez Sanz states that lathyrism is expressed clinically by spastic paraplegia, while pathologically it is a food intoxication due to eating the seeds or legumes of various species of the genus Lathyrus, which belongs to the pulses or leguminosæ. The disease is not rare in Spain, and the author reports cases in two brothers, aged respectively 26 and 19 years, who had always been healthy. In December, 1915, they left home to work in an olive oil mill, living chiefly on cakes made from the flour of the

chick pea. Not until March did they notice simultaneously a sluggishness in the legs, due to stiffness. The condition became progressively worse, contractures developed, and the men could no longer work. Aside from this affection of the lower extremities the health was unimpaired. In April they returned home, and under changed diet and environment the condition was arrested. The author saw them and at the request of authorities made a complete study of the cases. The men were in perfect health, aside from paraplegic symptoms. Urine and feces were voided laboriously by one brother, while the other complained of priapism. There was a spastic paresis of the lower extremities, muscular hypertonia, contractures in extension, increased tendon reflexes—especially the patellar—foot clonus, Babinski's sign, typical spastic gait. The younger brother could walk only with two canes, and could not climb stairs, while the older used a single cane. There were absolutely no distinctively nervous symptoms aside from the preceding. All the ordinary causes of spastic paraplegia could readily be eliminated, for this affection is nearly always symptomatic. By exclusion the diagnosis of lathyrism was reached, and was clinched by the history of the chick pea diet. Some predisposition must have been present, since both brothers were attacked in the same time and manner. Typical lathyrism differs from the preceding cases in appearing brusquely, with general disorders, fever, and lumbar pains. In order to fix the identity of the poisonous pulse the author identifies it with the Licia sativa, or common vetch, and the English chick-pea, or chickling-vetch. How such bland substances can produce alimentary intoxication is not understood. Many people eat of them with impunity, and the toxicity may proceed from some secondary modification. The disease has never been produced in animals, and autopsies on human beings have thrown no light on the mystery. The author does not mention familial spastic paraplegia under differentiation.

La Presse Médicale.

November 23, 1916.

Case of Chronic Giant Urticaria: Cure by Antianaphylaxis.—Pagniez and Pasteur Vailory-Radot report the results of a physiopathological and therapeutic study of a case of giant urticaria, and consider in this connection anaphylaxis and antianaphylaxis. Urticaria begins as a vasculohematic crisis, and the authors followed up the case, arriving at important prophylactic conclusions which have to do with anaphylaxis. The patient was a healthy man of 29, and the crisis appeared suddenly in the form of angioneurotic edema, later passing into that of giant urticaria. The lesions were of the wandering type, appearing in succession in various localities on the surface. Individual lesions persisted for several hours. Changes in the diet did not appear to exert any influence on the progress of the disease. Pressure on any point in the integument, if sufficiently prolonged, produced a great wheal of urticaria factitia. Hence patient was unable to carry burdens on his shoulder. Scratching also produced hives. The malady became chronic in its duration, although its expression remained acute. The patient, highly intelligent, feared a fatal attack of edema of the glottis. Only one practical lesson had been learned, to wit, that fasting for three days caused a cessation in the outbreak. Of various foods tried after starvation, milk and eggs were notably bad for the disease, while both the mixed and vegetarian regimens evoked a medium degree of lesion. Under a pure carbohydrate diet the lesions ceased to appear. Hence, protein, whether vegetable or animal, could provoke the eruption, the latter form being the most active. The patient was placed on a diet of bread, potatoes, bananas, vichy and wine, in order that a research for anaphylactic phenomena might be instituted. In one-half hour after the first meal pruritus first appeared; in six hours the leucocytes had dropped from 5600 to 2800, while at the same time there was a notable drop in the blood pressure. At the eighth hour the eruption of wheals appeared, although in the meantime the leucocyte count and blood pressure had become normal. The patient was now made to fast three days, and tried out again with animal albumin—eggs and milk. In one hour after the repast generalized pruritus developed. Several hours passed, and only a few small hives had appeared; then simultaneously the leucocyte count and blood pressure began to fall, and the urticarial crisis promptly followed, pruritus became intolerable, followed in twenty minutes by the appearance of large wheals. It is evident that a blood crisis (hemoclasic crisis of Widal) had preceded the skin crisis, as the giant wheals never appeared unless preceded by both these crises. Meanwhile, no progress toward a cure had been made. Treatment of the anaphylactic factor by calcium chloride had long ago been proved valueless. Injections of adrenalin during a severe paroxysm were able to relieve the pruritus, and favorably influenced the wheals. Blood was at once withdrawn, and was found to give no precipitate with egg albumin, although the blood before injection had given a notable one. However, no marked effect could be obtained on the course of the disease. Injection of the patient's own serum distinctly aggravated the trouble. An attempt at antianaphylaxis was now made. As injections were not practicable, a similar procedure per os was carried out. The patient was first fed very small rations of the very substances which had caused the anaphylaxis, viz., bread, 2 gm.; boiled potato, 6 gm. One hour later he received 200 gm. boiled potato, 100 gm. haricot beans, two bananas, 200 gm. bread, 250 c.c. wine. This scheme worked beautifully, and no urticarial crisis followed the meal. As far as known this idea, the author claims, is one which is quite new in therapeutics; a minute quantity of the offending food acting to protect the organism from the anaphylactic shock which follows the ingestion of large amounts.

Axillary Temperatures.—Fürbringer states that a wet armpit usually gives a higher reading than a dry one, the difference averaging two-thirds of a degree. It is, however, not practicable to dry the armpit, for sweating is resumed during the sojourn of the thermometer in this locality.—*Zentralblatt für Gynäkologie.*

Dietary Study—British Beef Stew.—Aulde gives the formula for the 6,000,000 cans of beef stew said to have been ordered for the British Army. Each man is probably entitled to a can a day. The weight is 13 ounces, divided up as follows: Cooked beef, 6 ounces; rice, 4 ounces; beans, 1 ounce; onions, 1 ounce; carrots, 1 ounce. The total amount of calories is 922. The beef must be quite fat, for the per cent. of the latter is somewhat in excess of the protein. The carbohydrate content is small, but of course there is no attempt at a balanced ration. If we reckon the latter at protein 50, fat 50, carbohydrate 200, the stew contains protein 50, fat 60, carbohydrate 37. It is very easy, however, to balance this ration with bread and potatoes, one or both. The chief mineral content is calcium and magnesium oxides, each about 1½ grains per can. Of the 363 grams of stew 294 are utilizable.—*The Medical Times.*

Society Reports.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

One Hundred and Eleventh Annual Meeting, Held November 27, 1916.

THE PRESIDENT, DR. FREDERICK E. SONDERN, IN THE CHAIR.

Election of Officers.—The following officers were elected to serve for the year 1917: *President*, Dr. J. Bentley Squier; *First Vice-President*, Dr. Charles H. Peck; *Second Vice-President*, Dr. Ludwig Kast; *Secretary*, Dr. Daniel S. Dougherty; *Assistant Secretary*, Dr. J. Milton Mabbott; *Treasurer*, Dr. Frederic E. Sondern; *Censors* (to serve two years), Drs. William S. Gottheil, Ward B. Hoag, and Alexander Lyle.

Report of the Counsel.—Mr. GEORGE W. WHITESIDE presented this report. He stated that the efforts of the counsel directed to the activities of quacks operating the so-called medical offices and institutes which were raided during the spring of 1915, had, during the current year, discontinued their most objectionable features and had conducted their places in a manner not only less offensive to public decency, but more equitable to the unfortunates who were allured to these places by the magnetic advertisements circulated by means of the press. The complaints against these places during the past year had been very few indeed, and where a victim had presented a just cause the counsel had been enabled to be of assistance to him or her. The counsel felt confident that the fear of the law was still in the hearts and minds of these men and while it was not possible under our present law to drive them out entirely, still, because of the efforts of the society, the counsel was of the opinion that their practices would not be so vicious in the future as they were a year ago. The so-called museums of anatomy, successfully raided and closed up during the spring of 1915, had not reopened and today the county was practically free from this form of indecency. Mr. Whiteside then presented a detailed account of the prosecutions against individuals alleged to have been practising medicine illegally and also a record of the cases now pending in the Court of Special Sessions. He said that the complaints received during the current year had not been quite so numerous as those received during the previous year. This was due to the fact, undoubtedly, that the records of the prosecutions established during the fiscal year of 1915 had served, and still continued to serve, as a deterrent to those inclined to disregard the laws regulating the practice of medicine. They had received during the year, however, 122 complaints, which were classified and presented. Among the decisions under the medical law there had been none handed down in this State which affected the interests of society so much as the decision of the Court of Appeals in the case of People *versus* Willis Vernon Cole. The court had squarely held that the practice of healing by Christian Scientists was a religious tenet of a church, and, therefore, Christian Science healers were exempted from prosecution so long as that provision of the statute remained. Counsel stated that he had given this matter considerable thought and attention and had come to the conclusion that if the public was to be protected, some drastic preventive measure ought to be taken that should not be designed or interpreted as interfering with the religious liberty of any part of the community, but which should safeguard the public health of the community by strengthening the arm of the law in dealing with those who would improperly, for personal gain, take advantage of the situation which the Cole decision had created. Under the present law a license to practise medicine might be procured either by following laboriously the necessary course in elementary study—devoting years of one's life to the preparation—or, in an instant, by embracing and professing the tenets of any church or faith the creed of which provided for the healing of human disease. Needless to say, a person bent on perpetrating a fraud upon the public would not choose the laborious and lengthy method of procuring his right to practice, but would find it more convenient and possibly as lucrative to suffer a sudden conversion to some form of religion which permitted him, within the law, for money to undertake the healing art. A proper and vigorous appeal to the Legislature must be made to prevent such an absurd and ridiculous perpetration of fraud; this should be done with due respect and complete recognition of the rights of all classes who enjoyed and had complete religious liberty. Another case of interest was the prosecution that was being conducted against the Gatlin Institute of New York, Inc. The charge alleged in the prosecution was that said institute, as a corporation, was practising medicine and that its manager and organizer was aiding and abetting the corporation in its illegal practice. They had in this State at the present time decisions to the effect that a corporation might not advertise to practice medicine unless it was a corporation, such as a hospital, organized under the membership Corporation Laws of New York State. The Court of Special Sessions acquitted the institute and subsequently action was brought against the society for malicious prosecution. The counsel had appealed from a judgment in this matter and expected to argue the case for the society before the Appellate Division during the current month. The cardinal question was "Might a corporation practise medicine, as a corporation, by hiring registered physicians to make the diagnosis and prescribe the treatment?" It was the hope of the counsel that the Appellate Division, in rendering its answer to this question, would make its decision so full that the necessity for raising this question might never again arise in the courts of this State. Pursuant to the instructions of the Comitia Minora, counsel drafted a proposed bill for the purpose of dealing with the evil of venereal disease, abortion, and similar advertising by registered practitioners. This bill had been approved by the Public Health Committee of the County Medical Society and was thereafter approved by the Comitia Minora and forwarded to the Public Health Committee of the Medical Society of the State of New York for its consideration.

Report of the Committee on Public Health.—Dr. FRANCIS CARTER WOOD presented this report, in which he stated that this committee had received a copy of a letter sent to the president of the society asking the society to take action on the following resolutions: "*Whereas*, it has been proven that alcohol has a pernicious and injurious effect on the public health of the country in that it lowers the resistance of the individual to disease, thereby disposing to tuberculosis and other diseases, and, *Whereas*, it is one of the chief contributing factors to poverty, misery, and crime, *Therefore*, We, the New York County Medical Society, place ourselves on record as opposed to its use as a beverage and strongly recommend its use only on medical prescription." The Public Health Committee recommended that the society express its approval of the campaign of the Department of Health of New York City against the widespread use of alcoholic beverages. Mr. Whiteside, in the course of his work as counsel of the society, had found the need of further restriction of advertising on the part of quacks and had proposed the following amendment to Section 170 of the Public Health Law, making it read as follows: "The Regents of the State of New York may censure, suspend from practice, or revoke the license of a practitioner of medicine or annul his registration (or do both) in any of the following cases: . . . (*e*) One who advertises to practise medicine under a name or designation other than his own; or makes, publishes, disseminates, circulates, or places before the public, or causes either directly or indirectly, to be made, published, disseminated, circulated, or placed before the public in this State, in a newspaper or other publication, or in the form of a book, notice, handbill, postbill, circular, or pamphlet, or advertisement of any sort, regarding service, treatment, care, or medicine, offered to the public, which advertisement contains any assertion or misrepresentation of fact which is untrue, deceptive, or misleading, or which offends public decency or morals; (*f*) Who advertises that he can or will restore manly vigor, lost manhood, lost power, or cure stricture, gonorrhea, tuberculosis, or cancer; or (*g*) who advertises any treatment for a woman in a manner that is calculated to lead another to believe that such a treatment refers to abortion, by whatever name such treatment is called or described." The Public Health Committee, after very careful consideration, approved of these amendments.

The above reports were accepted and referred to the Board of Censors.

Report of the Legislative Committee.—Dr. SAMUEL J. KOPETZKY presented this report. He stated that during the past year they had had before them and acted on about eighty-six proposed bills. Of these twenty-three were of such a character that no action was rec-

ommended, thirty-five were approved for reasons specified, and twenty-eight were disapproved. As in previous years many attempts had been made through proposed legislative enactments to threaten the public health by permitting various cults and "isms" to practise medicine. During the year just past no measures of this nature ever reached the floor of the Legislature; they were all killed in committee. There was passed at the last session of the Legislature a bill technically known as "An Enactment Law," which provided authority to boards of aldermen in the larger cities to issue licenses to massage parlors and the practitioners of massage, but also permitted the issuance of a license to all others who practised cures without resort to drugs, as, for instance, osteopaths, naturopaths, chiropractors, etc.; and the board of aldermen were to delegate to the commissioner of police, the commissioner of licenses, and the commissioner of health the power to formulate the qualifications of those whom the city was to license. This measure was defeated. Heretofore, the profession had at most expended its energy through the activities of its various committees on legislation in opposing proposed bills which threatened public health. During the past year their efforts had taken an additional direction and they had begun to engage in constructive legislation. For some years the Regents had been at work on legislation that would better control the practice of medicine so as to protect the lawful practitioner and to discipline the unlawful one. For the last three years the measures submitted to the Legislature had been unsatisfactory to the profession and had been successfully combated. Last year the bill was finally withdrawn with the understanding that the profession could voice its opinions regarding it and have its own will written into the proposed bill. The chairman of this committee therefore submitted the following: 'That the power to issue and to grant the privilege to practise medicine, their preliminary standards having first been met, resided in the Regents of the State of New York, and under the present law they also had the power to revoke the right to practise. The definition of unprofessional conduct, which the Regents proposed as a cause for revocation of the right should not include questions of ethics. Guilt of a breach of ethics did not constitute a breach of law and the medical profession did not deem it advisable to enact legislation making breaches of ethics a misdemeanor or other degree of crime. Finally the contention was submitted of the right of the medical profession to be judged on medical questions, not by laymen, but by medical men, reserving to the members of the profession without prejudice final resort to courts of law for the review of all proceedings under the proposed act. The machinery to make these contentions effective was suggested in the form of courts of honor composed of medical men to hear, to take testimony, and to make recommendations to the Regents in any given case of unprofessional conduct or other act on the part of licensed doctors of medicine. It was the opinion of the chairman of the Legislative Committee that such a law when introduced should have the support of the medical profession. It would raise the standards of the profession, place the discipline of their brothers in their own hands, and would do much toward regulating the practice of medicine, because the law would embrace the whole profession, whereas, the State Society and its constituent bodies, the county societies, could reach, discipline, and control only their own membership.

In the matter of the Compulsory Health Insurance Bill, which was introduced into the Legislature last year, there was recorded their effective opposition. Since the defeat of this bill through cooperation of the special committee appointed by resolution of this society under the chairmanship of Dr. Fisher, constructive work had been done on this bill. An outline of the postulates written into this bill were as follows: "1. The profession shall be represented on the administration board of the public health insurance department. 2. On all subdivisions of the administration department there shall be medical representation. 3. All legally qualified practitioners shall be eligible to serve on panels, namely, to serve with pay to treat the sick coming under the act. 4. No physician shall have on his list more than 1000 persons or more than 500 families. 5. There shall be a reasonably free choice of physicians by the sick. 6. The Department of Health of the State, the city, and other geographical subdivisions, shall be represented on the administrative boards in an advisory capacity so as to safeguard the public health. 7. Supervision over the sick coming under this act, the detection of malingering, the issuance of certificates entitling the recipient to cash benefits shall be left to salaried physicians employed by the carriers of the insurance. 8. There shall be a complete separation of the two medical departments, the one which treats the sick and the other which looks after the interests of the carriers, the funds, and the association. 9. Salaried physicians shall be protected in their positions by extending the civil service laws to cover their positions. 10. Provision shall be made so that the panel physicians do not bid against one another for these jobs, but rather have the law so drawn that group contracts are favored. 11. All disputes arising under the administration of the Insurance Act, between physician and physician, physician and patient, physician and carrier, as well as in addition all other matters, including fees for service rendered, shall be heard, tried, and decided by bodies of physicians rather than laymen. 12. The various medical committees and boards upon which physicians serve shall be representative and measures on them shall be obtained by vote of the physicians themselves." It was the sense of this committee that the measure as it would be presented to the Legislature this year would amply protect the public health, and that its medical provisions would be found on the whole satisfactory. Therefore the chairman recommended that the County Society take no action either for or against compulsory health insurance as a measure, but he recommended that the proposed draft of the medical sections of this bill as drawn receive the support of the society. In closing, Dr. Kopetzky recommended that, as the present legislative committee represented only a part of those legally qualified to practise medicine, the formation of a Commission on Medical Legislation, to which all organized medical societies could send duly elected or appointed representatives, which should create the machinery to keep track of the proposed legislation, ascertain the will of the profession, and study and report to the medical societies represented, should be established. It should in no sense become a medical lobby.

Report of the Special Committee on Compulsory Health Insurance. — Dr. EDWARD D. FISHER reported that this committee had also drawn up a set of recommendations. These contained in a briefer form practically the same postulates that Dr. Kopetzky had embodied in his report.

The report of the legislative committee was accepted in so far as it had reference to past activities; the portion relating to the compulsory health insurance was not accepted. The report of the special committee on compulsory health insurance was accepted.

Report of the Milk Commission.—Dr. ROWLAND G. FREEMAN presented this report, in which he said that the work of the milk commission had been carried on on the same basis as usual. They certified at the present time more than 17,000 quarts of milk daily. The milk was produced on thirty-three different farms, all of which were visited by an inspector, who had made 242 visits during the year. They were now inspecting for three other milk commissions, the Milk Commission of the Medical Society of Westchester, the Milk Commission of the Medical Society of the Bronx, and the Hudson County Medical Milk Commission. The use of the Widal test to exclude typhoid fever carriers among employees had been continued, 653 employees having been examined. These were practically all the employees on the farms producing certified milk. The commission had undertaken to investigate the relative advantage of goats' milk in comparison with cows' milk. Ten goats were now kept in Central Park, and the milk was sent to two institutions that cared for babies, where a careful comparison of the results obtained was being made.

Motion Photographs as Adjuvants to the Teaching of Surgery.—Dr. JOHN A. WYETH made this presentation. (*See* MEDICAL RECORD, Nov. 18, 1916, page 919.)

The Technique of Painless Radical Cure of Hernia Under Local Anesthesia.—Dr. JOHN A. BODINE gave a motion picture demonstration of the technique of this operation, which he prefaced by commenting on the frequency of hernia and its importance as a factor lowering the capacity of the individual. He stated that in the examination of men for military service it was found that the presence of an inguinal hernia detracted from 15 to 50 per cent. from the normal

capacity of the individual. Furthermore, there was a certain death rate connected with it owing to the possibility of strangulation. Out of every ten men having hernia, it might safely be estimated that there were nine who preferred to wear a truss to one who chose to submit to an operation. Of all operations there was none so well established as that for the radical cure of inguinal hernia. It was never necessary to give a general anesthetic for this operation. The operation could be performed under local anesthesia with as little pain and inconvenience to the patient as that of filling a tooth. The local anesthetic which he used was 0.5 per cent. novocaine. If one used cocaine the operation could be proceeded with almost immediately, but after the injection of novocaine one should wait at least five minutes before making the incision. A feature of special importance in the technique was the finding of the ilioinguinal nerve and blocking it by the injection of the local anesthetic before it divided into its branches. This nerve should be sought in the upper angle of the incision and a deep incision should not be made in the lower portion of the incision until this nerve was blocked. Dr. Bodine said he could not understand why this operation was not more generally taught and practised among surgeons, since it was so uniformly successful and required no special skill; even the house surgeons were permitted to perform it.

Dr. JOHN A. WYETH said that this operation was so safe and so simple that it had been performed over 3,000 times with only one death, and this one not due directly to the operation. It might be considered absolutely free from danger.

Dr. J. HERMAN BRANTH said that he wished to say a few words, as he had been on the sharp end of the knife when Dr. Bodine had been on the other end. He had been operated on for a direct inguinal hernia last spring, from which he had suffered for about two years, and by which he had been almost entirely invalided, though well otherwise. He was past 75 years of age and had had an attack of dilatation of the heart. The operation for hernia as Dr. Bodine performed it was not painful to the patient. After the injection of the novocaine the patient could feel the touch of the instruments, but nothing more save a general hot burning sensation over the whole surface. About eight hours after the operation followed a period of severe pain, which, under ordinary circumstances, could be assuaged by morphine, but as he had an idiosyncrasy against morphine, castor oil, strong alcoholics, and cocaine he had to stand this pain. Except for extreme tenderness of the region he was today well. Hernia should be classed as a major operation. There were no two cases exactly alike, and the surgeon's ingenuity and resourcefulness were taxed in every case. As there was no novocaine in the market at the present time, the speaker said he used a formula, 1/3 cocaine hydrochlorate and 2/3 eucaine B. in a large quantity of water. He took only one or two small crystals like granulated sugar and twice as much eucaine in a wineglass full of water. He had removed a large cancerous tumor from the neck some time ago, one that interfered with deglutition and respiration, and had produced conditions under which the patient's life could not last more than a few days. In this case he used 1/250 gr. of cocaine and 1/125 gr. of eucaine. The operation lasted over an hour. The patient got up from the table and walked to his room, returning home the following day. He lived two months with much comfort and died of general cancerous cachexia and cancerous invasion of the carotid artery.

The Approach and Entrance to the Kidney for the Removal of Calculi.—Dr. CHARLES H. CHETWOOD exhibited motion pictures illustrating this subject. He described the technique in three stages: the first, the approach through the skin; the second, the mobilization of the kidney, and, third, the operative interference proper. For the exposure of the kidney either the transverse or the perpendicular incision, as might appear most convenient, might be used. If on inspection removal of the kidney was indicated, it might be necessary to enlarge either one of these incisions or to combine both of them. The mobilization of the kidney was the most important step; sometimes this was a very simple matter, as when one found a prolapsed kidney, while at other times it was a perplexing and difficult matter, as in cases of tuberculosis of the kidney or numerous calculi. In the case which was chosen for demonstration it was found after mobilization that numerous calculi were present and removal was indicated. As the preliminary tests of the function of the other kidney had been made and its secretory capacity was normal a pyelithotomy and a nephrotomy were performed. The extirpated kidney confirmed the diagnosis of dilated pelvis that had been made by collargol injections, and also the wisdom of removing the kidney since there still remained a number of calculi.

Operation for Repair of Rectocele.—Dr. THOMAS H. MORGAN demonstrated this operation by means of motion pictures. He stated that there was nothing new in the technique of the operation except the disposal of the flap. There was no method by which one could see his faults in operating equal to the moving picture. In reviewing the technique of this operation, Dr. Morgan called special attention to the dissection of the pubo-coccygeal muscles, which he said one should reach by dissecting high up and never in the direction of the pubes; in order to find these muscles he must go backward, outward and downward and should not dissect the deeper part of these muscles from their sheath. In suturing the perineum he worked from the back forward, leaving the last stitch open and catching the vaginal flap in this last suture; he then removed redundant tissue. He found kangaroo tendon, No. 2, most satisfactory for suturing in these operations.

NEUROLOGICAL SOCIETY OF NEW YORK.

Three Hundred and Fiftieth Meeting of the New York Neurological Society, Held in Conjunction with the Neurological Section of the New York Academy of Medicine, Tuesday, November 14, 1916.

PRESIDENTS, DRS. WILLIAM M. LESZYNSKY AND FOSTER KENNEDY.

Idiopathic Epilepsy.—Dr. JOHN T. MACCURDY read this paper, which he said was not an argument in favor of epilepsy being a disease of ultimate psychic origin, but a report of some mental phenomena which he thought to be of diagnostic value. A striking clinical experience led him to formulate the hypothesis that epilepsy was a disease characterized by a functional instability of consciousness and control of muscles wherein both were lost in crises and that the excitement of the aura, when present, might contribute such a crisis. To test this view, the auras of idiopathic epileptics were studied. These studies revealed the following: (1) That no primary motor aura existed in idiopathic epilepsy, all movements being apparent reactions to primary sensations; (2) that every aura was accompanied by a painful effect, usually fear, directed against the convulsion which was felt to be impending; (3) that auras always occurred apart from convulsions as well as preceding them; (4) that the patient always felt that if he could distract his mind the fit would be averted, for which conviction there was good objective evidence; (5) that the symptomatology of auras corresponded closely to that of neuroses and psychoses, occurring independently of epilepsy, so that they might not be epileptic symptoms in essence, but concurrent attacks that were psychologically determined. In general one could say that the attitude of the idiopathic epileptic toward his aura was subjective and rather hypochondriacal. The auras of pure Jacksonian cases, on the other hand, were often primarily motor; the sensory component was not so prominent and the attitude of the patient was objective rather than subjective. The patient, as a rule, felt no fear, and never believed that disregarding his symptoms would ward off the attack. On the contrary, he thought that a concentration of attention on the part affected was more apt to abort the attack. This difference of attitude should be a valuable point in diagnosis when neurological signs were absent, particularly if operation be thought of. Some histories seemed to show that a case might begin as Jacksonian epilepsy and develop the idiopathic disease as the former was being recovered from. Such cases showed a change in auras from the objective to the subjective type. One could probably not hope to cure epilepsy by the removal of the aura, for a patient might substitute another if one disappeared for any reason. Therapy, in so far as it was mental, should be directed toward relieving the stress, either internal or external, which tended toward creating crises.

Dr. L. PIERCE CLARK said that he had looked over his

own cases in the light of Dr. MacCurdy's contention as to the significance of the aura in idiopathic and organic epilepsy, and had found it in the main to be true. Unfortunately, but a third of the cases of epilepsy had any sort of aura upon which one could place a differential dependence. He was rather inclined to consider the aura as really a part of the attack, and not as a separate phenomenon. He thought there was some reason to think the fear element in idiopathic cases was due to the automatic conscious repression of the inherent and underlying demands for the psychic expression of the unconscious, and thus a riddance from the type of stress and irritation present in the individual's life, thereby producing fear as a result of such conflict. It might also be true that the fear element, not being present in the Jacksonian cases, was due to the gradual loss of consciousness in which the individual had an opportunity to adjust himself to all the possibilities of an attack and its accidental consequences. The fear in idiopathic cases might be due to the sudden threatening of the loss of consciousness. It was interesting to note that probably the great value of mental distraction in doing away with the fear, which had been universally practised since ancient times, had some good justification on psychic grounds. He called attention to the fact that many writers, such as Gowers, had indicated that hemiplegic epilepsies had a tendency later on in life to take on the clinical sequence of ordinary idiopathic attacks. It was interesting to note, though, in such cases finally showing idiopathic attacks, that the fear element was not added in their aura. He would not be inclined to agree that the consequential epileptic phenomena, after the focal lesion of the brain had been removed, should be considered as a neurosis, but rather idiopathic epilepsy initiated by a traumatic factor. He thought that Dr. MacCurdy's point of not depending upon certain types of convulsive movements for operations on the cortex was quite sound; it indicated clearly that we should still depend upon paralytic phenomena and alterations in the reflexes as diagnostic criteria for any focal operation on the brain in which epileptic attacks were to be treated surgically.

The Management of the Recent Epidemic of Poliomyelitis in New York City, from the Neurologist's Viewpoint.—Dr. WILLIAM M. LESZYNSKY stated that a meeting of the Council of the New York Neurological Society was held on October 12, 1916, for the purpose of discussing the management of the recent epidemic. A committee, consisting of Drs. F. Tilney, B. Sachs, C. L. Dana, W. Timme, and W. M. Leszynsky, was appointed to survey the field. Clinics were visited in order to ascertain the scope of the work. Conditions were found to vary at the three large orthopedic institutions, but, owing to lack of funds, facilities and equipment were entirely inadequate. Treatment was limited to braces and massage, and no neurological observations were made. Two hundred, three hundred, and two hundred patients were treated respectively in each; in one only was neurological aid sought. At Bellevue Hospital and Cornell Medical School there was cooperation of neurologists and orthopedists. At Mount Sinai Hospital and the Neurological Institute patients were supervised by neurologists; at all other dispensaries patients were treated in the orthopedic departments. In 1907 the epidemic in New York, comprising about 2,500 cases, was not discovered until the large number of paralyses in children attracted attention in the dispensaries. No official measures were instituted, but in October, 1907, the Neurological Society appointed a committee, consisting of neurologists, pediatrists, bacteriologisis, and orthopedists, to study the epidemic of that year. Results of careful analyses of 752 cases were embodied in a volume called "Epidemic Poliomyelitis; Report of the Collective Investigation Committee on the New York Epidemic of 1907." This fully demonstrated the interest of the neurologists in the disease. Since then the Health Department had been active in quarantining and controlling the disease, but the report of the Neurological Society seemed to have been disregarded or forgotten. In the recent epidemic the value of cooperative neurological study had been entirely forgotten or ignored and no official action had been taken by the New York City Health Department to request the cooperation of neurologists, either in committees of the city administration or those for after-care. Of the Committee for After-care, there were fifty-three members, twenty-five of whom were physicians, but only three of these neurologists. Furthermore, the New York City Health Department had provided information to parents only as to where orthopedic treatment might be obtained. Thus the entire medical control was in the hands of orthopedists. These remarks, the doctor stated, were not meant in any spirit of rivalry. It was, however, universally admitted that poliomyelitis was a disease of the central nervous system, and the disease had hitherto been assigned to the province of neurology, so that the state of affairs as above described was the more extraordinary. The scientific interest of neurologists in the disease, however, could not be so easily eliminated. It should be added that the care by orthopedic institutions was probably a matter of expediency rather than medical selection or preference. If the children were being properly cared for their condition could be properly studied through suitable medical cooperation. The importance of preventive measures, immunization, and laboratory research was fully realized. There should, however, be a standardization of treatment to suit individual requirements, and the best interests of the patients would be served by harmonious cooperation of orthopedists, pediatrists, and neurologists. Disabled children should not be deprived of any benefit resulting from associated service.

The Present Methods of Management of Poliomyelitis in New York City.—Dr. FREDERICK TILNEY made this presentation. He said that last spring preparedness was preached, and after some excitement they were satisfied that they were sufficiently prepared. In the summer came the epidemic, the third in nine years, and found them unprepared. Quarantine was a travesty, and hospitals were not ready. The measures for proper clinical management were lacking, and the opportunity to increase knowledge of diagnosis, prognosis, and treatment was not recognized. Owing to lack of intelligent organization, the epidemic would have to go down into history without scientific record. Treatment of the acute stage fluctuated between radical experimentation and conservative expediency. The after-treatment lacked the necessary organization. Patients were recommended to attend certain clinics, and there the matter ended. The victims of the epidemic needed the best help of the medical profession and to give this, the adequacy of the means now in force had to be considered. A study of the ten largest institutions showed that they had had the care of about 3,000 cases, and a clinical plan of treatment should determine which departments should care for the patients and also which departments should work together. Classification for the grouping of cases should be made and patients should be individualized with reference to therapeutic needs and after-care. Careful records would have to be kept of the cases of paralyses and reexaminations made at stated intervals. Although all cases were treated in orthopedic departments, only 30 per cent. were receiving strictly orthopedic treatment. Few patients had neurological care. As the disease was essentially one of the nervous system, the services of the neurologist must have value. Cooperation between the neurologist and the orthopedist had been lacking. As 64 per cent. of children were under five years of age, muscle education in these ages was impossible. After five years it could be successfully done. Only the neurologist could make the distinctions between the groups of cases as regards types of involvement. He should judge the advisability of electrical treatment for particular cases. A particular type of current was indicated—the galvanic sinusoidal, a slow wave current with alternating polarity. In conclusion Dr. Tilney said that what was most needed at present was a comprehensive plan of organization. The suggestions offered by him covered the following points: (1) The neurologist should direct the after-care of patients; (2) cooperation between neurologists and orthopedists was the ideal plan; (3) classifications of cases should be made by neurologists; (4) reexaminations should be made at stated intervals to classify methods of treatment; (5) there should be a distribution of cases according to the institutions most accessible to the patients; (6) every therapeutic means sanctioned by good authority should be employed; (7) institutions should adopt certain regulations as to staff organizations, with special reference to the number of physicians, nurses, and masseuses per number of patients. Equipment of institutions engaged in the after-care should be brought up to a desired standard.

Diagnosis and Treatment of Poliomyelitis.—Dr. B. SACHS presented this paper. He said that he would single out points of special interest which would bear on the proper future diagnosis and treatment of polio-

myelitis. The duty of the neurologist to the public was twofold—first, to assist, if possible, in prevention of another epidemic; second, to lay down sensible rules for the public in the matter of treatment. Little was known about transference of the disease from one person to another. It had appeared in a crowded section of the city, spread rapidly, and then had appeared in other parts of the country, evidently spread by healthy carriers and also by intimate contact with those afflicted with the disease. Contagion was probably most frequent in the prodromal stage of the disease. In families children had evidently caught the disease from one another, but in hospitals this had not occurred. Thus it appeared that intimate contact was necessary for infection. In the uncertainty of the exact method of transference it was necessary to advise strict quarantine and the greatest possible cleanliness in the home. The dirty conditions of the New York streets, with many uncovered garbage cans, invited epidemics, but the better care of children's food in the past summer had lowered the death rate from gastrointestinal disease so that the death rate was not higher than in non-epidemic years. Evidence had long been established that poliomyelitis was an acute infectious disease of microbic origin. Recently Peabody, Draper, and Dochez had laid great stress on the edematous appearance of the brain and cord, and concluded that the damage to the nerve cells was from direct pressure, by hemorrhage, edema, and exudate. The report of the committee of the Neurological Society on the epidemic of 1907 had evidently been forgotten in New York, but neurologists were familiar with this work and had noted greater virulence and higher mortality in the present epidemic. Since 1907 the work of Flexner and others had brought the possibility of treatment by immune serum nearer. The examination of the cerebrospinal fluid also had been found a valuable diagnostic aid. In some cases with intense infection the respiratory and cardiac centers were affected and the disease was rapidly fatal. In other less severe cases the gray matter of the cord only was affected, and in others the infection was so slight as not to produce paralysis. As regards treatment, the neurologist should always be chiefly responsible, now as well as formerly, when the laboratory worker could not be relied upon as infallible. Furibund forms always showed diminution of deep reflexes and muscle hypotonia, and a detailed neurological examination of the entire body was necessary. In the better known forms of the disease there was rapidly developing paralysis, which subsided in intensity, with first slightly increased, and then lost deep reflexes. Electrical reactions here were of great importance. Irritability was excessive in the first two days, followed by some degeneration. The neurologist should make the differential diagnosis between poliomyelitis and transverse myelitis, which was often difficult. In the early stages of the disease care in feeding and bathing of children and the manner of disposal of the limbs called for expert care and handling. Immune serum injection should be resorted to. Artificial respiration was of aid in cases with respiratory involvement. In after-treatment electrical examinations with faradic and galvanic stimulation should be made of all groups of muscles. Galvanic stimulation could be used to exercise muscles that could not be exercised by the will. Patient reeducation of the muscles by the mother or visiting nurse was highly valuable, also massage after warm baths. The crying need in these cases was for good visiting nurses; this was more necessary than spending public money on ambulances to convey children to the clinics. The neurologist should cooperate with the orthopedist as to the necessity of orthopedic appliances. Too early or too persistent use of braces was to be condemned.

Dr. Charles L. Dana said that with regard to the general management of the late epidemic, it was only fair to remember that nobody knew exactly what to do at its inception. No preparation had been made, because no one knew exactly how to prepare. He thought that the authorities did the best they knew how, acting on the best advice they could get. They made some mistakes, and one was undoubtedly that of ignoring tthe work and possible help of neurology. The speaker said that it was not now too late to introduce their services for the therapeutic work, since the victims of this epidemic would require treatment for a long time. He said that the public, and perhaps some of the faculty, did not realize that a considerable percentage of these victims would not need much treatment anyway. They had the infection, but no or very slight paralysis, and promptly got well. Another percentage of cases, viz., those with single and moderate paralysis involving only one segment of one limb, did not require elaborate treatment and largely improved under simple measures. There was another, a small percentage, in which the patients suffered enormously, having quadriplegic and triplegic paralyses often with involvement of the trunk. These required the most careful supervision and humane attendance, but were often hopeless so far as cure was concerned. There was a fourth group of cases, which included 30 to 40 per cent. of the whole, in which the paralyses were of considerable or moderate severity and distribution. These were the cases in which the very best treatment of every possible kind should be employed. It was this phase of the question which was largely being debated to-night. In further discussion the speaker said that there were two phases of the subject to be considered: one, that of the general management and organization of the institutions and individuals concerned in treatment, and the other that of the technical methods of treatment. With regard to the first, he thought that the New York Committee on After-care of Infantile Paralysis Cases was working earnestly and would, he believed, gradually bring matters into an efficient state. The speaker then went over the various measures used in treatment. Everyone, he said, agreed that warm baths, exercises, muscle training, and educational methods in general were definitely helpful. Some doubted the value of electricity; others acclaimed it. The speaker said that he did not give his opinion but simply his experience, which was that it was helpful in properly selected cases, and he considered it not only wrong but rather silly to take the position that it was useless when properly applied. He had never seen any direct benefit from massage, but thought it might be a useful thing indirectly if done carefully. There was no question as to the value of warmth or of the utility of exercising in warm baths. The same was true of the measures which gave support to the paralyzed muscles by approximating the ends and relieving the tension. There was a distinct difference of opinion between some neurologists and some orthopedists as to how much support by braces should be given and as to its extent and duration. Neurologists, among them the speaker, believed in allowing as much as possible normal physiological movements, allowing the child to lie on the bed or the floor and kick about, rather than to lock up the joints in positions of perfect anatomical adjustment. Practically, however, he said that there had never been any difference of opinion, when it came to individual cases, between himself and the orthopedist. Referring to the matter of prognosis, the speaker said that a psysiological fact, perhaps not generally known but of hopeful significance, was that the motor cells of the spinal cord practically increased in number from birth to adult life. Kaiser had shown that in the anterior horn of the cervical spinal cord at the time of birth there were about one hundred thousand cells and at the age of fifteen years about two hundred thousand cells. This did not mean that nerve cells actually divided and multiplied, but that minute nucleated nerve cells developed into full-sized functioning cells. Thus there was always hope in these cases of young children that nature was going to assist enormously the work of the therapeutist. The speaker concluded that, on the whole, it was better for us to take the position that all these therapeutic measures should be allowed under wise supervision. We did not, any of us, know enough to stand up and say, "Massage is of no use; electricity is of no use; vibration is of no use, and braces are of no use." This attitude would be unjust to the child and to our art. The essential thing was a sane judgment of what should be used in every individual case. We could only be absolutely sure that good came from wisely applied treatment and bad came from neglect or stupid and unintelligent treatment, whether this was by boluses or braces. We might be sure also that the general profession which both looked on and took part in this discussion would eventually pass final judgment, and the care of poliomyelitis would be taken to or stay with the pediatrist, the neurologist, or the orthopedist in accordance with the final test of experience. He believed it would come about that the cases would be assorted to each department in accordance with individual indications and the stage of the disease. But now, while we waited, it was only right that we should urge upon those who had any authority in dispensary therapeutics of the crippled children that they give the child *all* the measures known to be prob-

ably helpful when wisely applied, and surely this meant that they should secure the cooperation of good and soundly trained neurologists, for they were persons trained in dealing with paralyses, familiar with the anatomy and physiology of the disease, and able to give help in diagnosis and prognosis as well as therapeutics. He made the qualifications of *good* neurologist, because of the neurologist who dealt with the delicate mechanisms of the soul as well as of the body, it was especially true to paraphrase what Horace said of poets and poetry—"In some specialties mediocrity and tolerable endowments may properly be allowed, but neither gods nor men give any indulgence to middling neurologists."

Dr. M. Allen Starr said he could only add that every suggestion made by Drs. Sachs and Dana met with his approval. They had every right to use every method that they knew of as a therapeutic aid. He agreed with Dr. Sachs in regard to electricity. He had opposed its indiscriminate use for many years, but he thought that the use of electricity for the purpose of exercising muscles which could not be exercised by the will was certainly beneficial. A great many children could not use the muscles voluntarily. For two years after the onset of the disease constant improvement was possible. Exercise could be given by one kind of electrical current only; that was the galvanic. Faradism did nothing but scare the child. The sinusoidal current was the most efficacious. He thought electricity could be given properly with intelligent training by anyone, and six lessons to a careful and intelligent mother in the use of the galvanic battery should enable her to give it properly. This could not always be done with the tenement house population, and with this element it was well to bring the child to the clinic for electricity. As Drs. Sachs and Dana had pointed out, visiting nurses should be employed by philanthropic individuals, and this recommendation should be made to them. There was great benefit in graduated exercise under direction. Some years ago Dr. Fraenkel pointed this out and instructed them in the improvement to be gained in locomotor ataxia by adjusted series of movements. With the patient working by himself there was not much result, but with a trained instructor to carry out the training and help and encourage the patient very remarkable results were obtained. In educational exercises there must be someone to understand the object of the work. Dr. Starr had seen some work of Dr. Lovett's with a Harvard student, and he had succeeded in reeducating the muscles of his arm. This was done with the intelligent cooperation of the patient. As regarded massage, he thought it could be best done under water, and any mother could be instructed in this. He thought the Zander instruments were important. As regards braces, out of 404 cases there were 280 with paralyzed legs, 84 arm cases, and 40 of the face and neck reported in the epidemic of 1907. Orthopedic appliances would, then, benefit the 280 cases, but the remainder they would not affect. Thus a great many cases were not open to orthopedic treatment. The mind of the public had been unnecessarily directed to the question of braces, and it should be borne in mind that the brace which kept the muscle from recovering function was doing harm. Braces should not be kept on all the time.

Dr. E. D. Fisher said that he could hardly agree with the point of view that had been expressed, that there had been any antagonism between neurologists and orthopedists. He had seen many cases of poliomyelitis during the past summer and in the hospitals, and the opportunity was open to others. In regard to the treatment of the cases, it was not necessary for the neurologist to treat the case in the early stage. The neurologist could not take the credit for the discovery of the early stages; that work belonged to the laboratory. As regards the future of these cases, they must agree heartily with all the remarks of Drs. Starr and Dana. The combination of treatment should be by the orthopedists and the neurologists. He did not think that they had to blame themselves in this epidemic. Very careful work had been done and the results would be made clear later.

Dr. Walter Timme read some resolutions drawn up at a special meeting of the New York Neurological Society (see page 950).

Dr. Virgil P. Gibney said he felt that this had been exclusively a neurological banquet, and while listening to the various experiences he was reminded of a story of a young man who committed suicide by hanging himself to the limb of a tree, and the question arose why he did it. It was said because he was criticised. But if he were not criticised it were better that he commit suicide, as he would be a dead one already. The doctor said he agreed with many of the views that had been expressed during the evening. He was formerly a member of the society, and was even at one time put up as a compromise candidate for president. For many years he had employed faradism and galvanism and applied it to the treatment of paralyzed limbs. He got patients in the early stages and took measurements of the limbs, recording the results faithfully, and after thirteen years he came to the conclusions that Dr. Starr had expressed and he felt that galvanism was good as a diagnostic measure in obtaining the reaction of degeneration. He had referred many patients to neurologists and had also carried out the treatment they suggested. He had found the galvanic current was useful in a certain number of cases during the first year or two. He always told patients they could have electricity and massage if they wanted, but he did not assure them that the treatment would yield them the results they expected. He thought that paralyzed paients had a right to all kinds of therapeutics not harmful and holding out relief, however little. Warm baths could be of use. In the treatment of deformity they employed braces and plaster of Paris for a while, and when the deformity recurred, after allowing the limbs to go free, they used the braces again. He felt that though they were orthopedic men they did practise neurology just as faithfully as did the neurologists. In reference to Dr. Starr's remark as to the inapplicability of appliances to the upper extremity, he found that the deltoid had been paralyzed very frequently in this epidemic and they were constructing an appliance to lift the arm up and rest the deltoid muscle. He believed firmly in the theory that had been advanced, not to overtire a weak muscle. He remembered that Dr. Lewis A. Sayre used to say that you must not whip up a tired horse, and one must apply this to the tired muscle. As regards drop foot, they had to correct that deformity, and in spite of all treatment they were still working on the cases that occurred in the 1907 epidemic. They had given the patients electricity and massage; they had stiffened joints; and they had implanted tendons. The present epidemic was the most serious they had had, and the orthopedic men were willing to cooperate heartily with the neurologists.

Dr. R. H. Sayre said that it seemed to be taken for granted that the orthopedist did the patient up in plaster of paris and left to God his improvement. However, the orthopedist made use of all the means used by the neurologist.

Dr. A. H. Cilley asked if the strictures passed upon the Health Department in not using the services of neurologists were really well taken. Was it true that these services had been offered and refused? He knew of two neurologists that had been asked and they both were away.

Dr. William M. Leszynsky said that he had made the above remarks with deliberation and had every reason for his statements.

The Electromagnet in Military Surgery.—Cords states two procedures are in use, viz., extraction of metal splinters at a distance and employment of the magnetic sound with the same aim. They are both of undoubted value, especially in cerebral surgery.—*Zentralblatt für Chirurgie.*

Acute Hallucinatory Confusion, Optic Neuritis, etc., from Paint Fumes.—Besenbouch alludes to the frequency of untoward effects of the volatile principles in paints as experienced by painters. He relates a case in which the nature of the fumes was obscure. Benzol could be excluded, but the manufacturers admitted the use of a distillate of Borneo petroleum known as sanzajol. This statement was confirmed by an analysis. The toxic substance was also identified as putröl, a substitute for turpentine known for its disagreeable odor. The paint, a light green, was used on ships, especially for decorating small spaces, in which ventilation was poor. Numerous cases of poisoning had been reported, and a single case is given in detail. The victim made an eventual recovery. To prevent such accidents painters are warned not to converse, whistle, etc., while painting. The greatest possible ventilation should be secured, a portable ventilator being available. The shift should be only 3 hours long with an hour's intermission, to be spent on deck. The paint, pronounced relatively nontoxic, was not condemned.—*Archiv für Schiffs und Tropen-Hygiene.*

Blood pressure, its clinical applications, by George William Norris, 476.
Breathe and be well, by W. L. Howard, 30.
Burdett's hospitals and charities, 1916, by Sir Henry Burdett, 916.
Bureau of Laboratories, City of New York, collected studies from, Vol. VIII, 1914-15, W. H. Park, Director, 1051.
Cambridge public health series, post-mortem methods, by J. M. Beattie, 388.
Candy medication, by Bernard Fantus, 345.
Catarrhal and suppurative diseases of the accessory sinuses of the nose, by R. H. Skillern, 916.
Cerebellar abscess, by Isidore Friesner and Alfred Braun, 650.
Cerebrospinal fever, by Thomas J. Horder, 30.
Character and temperament, by Joseph Jastrow, 30.
Charaka Club, proceedings of, Vol. IV, 521.
Chemistry of metabolism, problems of physiological and pathological, by Dr. Otto von Fürth, trans. by A. J. Smith, 1051.
Chemistry, physiological, by Philip B. Hawk, 871.
Chemistry, physiological, by Albert P. Matthews, 962.
Christianity and sex problems, by Hugh Northcote, 1004.
Cleft palate and hair lip, by Sir W. Arbuthnot Lane, 434.
Clinics of John B. Murphy, Vol. V, No. 1, 434; Vol. V, No. 2, 388; Vol. V, No. 3, 784.
Colloid chemistry, a handbook of, by Dr. Wolfgang Ostwald; trans. by Dr. Martin H. Fischer, 121.
Dack family, by Mrs. A. W. Finlayson, 1004.
Diagnose und Therapie der Gonorrhoe beim Manne, von Dr. S. Jessner, 434.
Diagnosis and treatment, new concepts in; physico-clinical medicine, by Albert Abrams, 607.
Diagnosis and treatment of surgical diseases of spinal cord and membranes, by Charles A. Elsberg, 962.
Diagnostic methods, chemical, bacteriological and microscopical, by R. W. Webster, 388.
Diagnostico de las enfermedades del corazon, por Antonio Mut, 79.
Dictionary, practical medical, by Thomas L. Stedman, 1092.
Diet for children, by Louise E. Hogan, 827.
Digestive tract, diseases of, and their treatment, by A. E. Austin, 1004.
Dream problem, by A. E. Maeder, trans. by F. M. Hallock and S. E. Jelliffe, 738.
Endocrine organs, by Sir Edward A. Schafer, 476.
Ethics for nurses, studies in, by Charlotte A. Aikens, 563.
Eye, diseases of, by George E. de Schweinitz, 476.
Fièvre typhoïde et les fièvres paratyphoïdes, par H. Vincent, 1092.
Fire prevention and fire protection for hospitals, by Otto R. Eichel, 1051.
Food supply, changes in the, and their relation to nutrition, by Lafayette B. Mendel, 30.
Fractures and dislocations, textbook of, by Kellogg Speed, 521.
Fractures, modern methods of treating, by E. W. Hey Groves, 738.
Fractures, treatise on, by J. B. Roberts and J. A. Kelly, 607.
Gynecology, by W. P. Graves, 738.
Gynecology and pelvic surgery for students and practitioners, manual of, by Roland E. Skeel, 563.
Hay-fever, its prevention and cure, by W. C. Hollopeter, 300.
Heart beat, clinical disorders of the, by Thomas Lewis, 916.
Heart disease, diagnosis and treatment of, by E. M. Brockbank, 696.
Hysteria and accident compensation, by Francis X. Dercum, 300.
Infantile paralysis, treatment of, by R. W. Lovett, 387.
Infections of the hand, by Allen B. Hanavel, 916.
Instinct and intelligence, by N. C. Macnamara, 256.
International Clinics, edited by H. R. M. Landis, Vol. I, 1916, 256; Vol. II, 1916, 563.
International Medical Annual, 1916, 256.
Intestinal putrefactions; clinical studies of enterocolitis, by Charles F. Reckham, 476.
Italian for use in clinic, by Rev. Francis Bimanski, 650.
Johns Hopkins Hospital Report, Vol. XVII, 476.
Joy, influence of, by G. V. N. Dearborn, 827.
Kinetic drive, its phenomena and control, by George W. Crile, 563.
Localization by *x*-rays and stereoscopy, by Sir J. M. Davidson, 1092.
Makers of modern medicine, by James J. Walsh, 696.
Manual of practical nursery, by Helen L. Bridge, 434.
Massage, handbook of, for beginners, by L. L. Despard, 300.
Massage, practical and corrective exercises, by Hartvig Nissen, 1004.
Mayo clinic, Rochester, Minn., collected papers of, Vol. VII, 1915, edited by Mrs. M. H. Mellish, 871.
Medical clinics of Chicago, 1916, Vol. I, No. 5, 563; Vol. I, No. 6, 345; Vol. II, No. 1, 962.
Medical and surgical reports of the Episcopal Hospital, Philadelphia, vol. iii, edited by A. P. C. Ashhurst, 1138.
Medical practice, a treatise on, based on principles and therapeutic applications of the physical modes and methods of treatment, by Otto Juettner, 121.
Medical Record visiting list and physicians' diary for 1917, 1004.
Medicine, a treatise on the principles and practice of, by A. R. Edwards, 256.
Médecine opératoire, précis de, par A. Broca, 300.
Meningitis, el problema de la, por el Dr. César Juarros, 121.
Mentally deficient children, by G. E. Shuttleworth and W. A. Potts, 650.

Modern medicine and some modern remedies, by T. B. Scott, 784.
Monographs of Rockefeller Institute for Medical Research, No. 6, 696.
Mother, expectant, by Samuel W. Bandler, 1004.
Muscle training in treatment of infantile paralysis, by W. G. Wright, 738.
National formulary, fourth edition, 650.
Nervous children, by Beverley R. Tucker, 607.
Nervous disorders of men, by Bernard Hollander, 1051.
Nervous disorders of women, by Bernard Hollander, 1051.
Nervous diseases, textbook of, by Robert Bing; trans. by C. L. Allen, 256.
Nervous system, involuntary, by W. H. Gaskell, 521.
Nurse instruction for civil service examinations, 79.
Obstetrics, by Edwin B. Cragin, assisted by George H. Ryder, 79.
Obstetrics, normal and operative, by George P. Shears, 827.
Occupation and vocational hygiene, diseases of, edited by G. M. Kober and W. C. Hanson, 1092.
Operative midwifery, by J. M. Munro Kerr, 827.
Operative surgery, manual of, by J. F. Binnie, 387.
Ophthalmologie du médicin practicien, *521.
Otology for students and practitioners, manual of, by C. E. Perkins, 1138.
Painless childbirth, eutocia, and nitrous oxid-oxygen analgesia, by C. H. Davis, 256.
Pathology of tumors, by E. H. Kettle, 696.
Pathology, text-book of, by W. G. MacCallum, 1138.
Pediatria, Tratado de, Tomo I, por el Dr. Andrés Martinez Vargas, 962.
Perimetry, the principles and practice of, by Luther C. Peter, 434.
Pharmacy, year-book of, by J. O. Braithwaite, Thos. Stephenson, and R. R. Bennett, 300.
Physical diagnosis, principles and practice of, by J. C. Da Costa, Jr., 121.
Physician's visiting list, for 1917, 1004.
Physiology, human, by Prof. Luigi Luciani; trans. by Frances A. Welby, Vol. III, 79.
Plague, its cause and the manner of its extension; its menace; its control and suppression; its diagnosis and treatment, by T. W. Jackson, 476.
Polish for use in clinic, by Rev. Francis Bimanski, 650.
Practical medicine series, Vol. I, General Medicine, by Frank Billings, 650.
Practitioner's visiting list for 1917, 1004.
Profilaxis del Tifus exantematic, por el Dr. D. Manuel Martin Salazar, 916.
Progressive Medicine, edited by Hobart A. Hare, 521, 650.
Pye's surgical handicraft, edited and largely rewritten by W. H. Clayton-Greene, 1051.
Refraction of the human eye and methods of estimating the reaction, by James Thorington, 563.
Roentgenographic diagnosis of dental infection in systemic diseases, by Sinclair Tousey, 916.
Sex complex; a study of the relationships of internal secretions to female characteristics in health and disease, by W. B. Bell, 387.
Sex problems of man in health and disease, by Moses Scholtz, 871.
Sexual function in male and female, practical treatise in disorders of, by Max Hühner, 1138.
Skin cancer, by H. H. Hazen, 650.
Skin, diseases of the, by Richard L. Sutton, 916.
Spine, lateral curvature of the, and round shoulders, by Robert W. Lovett, 434.
Studies in surgical pathological physiology from the Laboratory of Surgical Research, Vol. I, 1915, 388.
Surgery in war, by Alfred Hull, 387.
Surgical anatomy, manual of, by Lewis Beesly, 871.
Surgical anesthesia, manual of, by H. B. Gardner, 388.
Surgical nursing and technique, by C. P. Childe, 738.
Surgical technique, aseptic, with special reference to gynecological operations, by Hunter Robb, 784.
Therapeutic by-ways, by E. P. Anshutz, 345.
Those about Trench, by E. H. Lewis, 607.
Tonsil and its uses, vocal, mechanic, and physiologic, by Richard B Faulkner, 345.
Tonsils and adenoids: treatment and cure, by Richard B. Faulkner, 345.
Torula infection in man, by J. L. Stoddard and E. C. Cutler, 696.
Tuberculosis, a preventable and curable disease, by S. Adolphus Knopf, 563.
Tuberculosis, pulmonary, rules for recovery from, by Lawrason Brown, 871.
Ultraviolet light by means of Alpine sun lamp, by Hugo Bach, 784.
University of Iowa monographs: Studies in medicine, Vol. 1, No. 1, edited by Prof. H. Albert, 1092.
Urine, examination of, and other clinical side-room methods, by A. F. Hewat, 962.
Venereal diseases, a manual for students and practitioners, by James R. Hayden, 434.
Venesection, by W. F. Sutton, 962.
Vital function testing methods and their interpretation, manual of, by Wilfred M. Barton, 345.
Books, medical, as evidence, 988.
Bothriocephalus latus infestation, 646.
Boudreau, E. N., the syphilis problem among confined criminals, 981.
Brachial plexus, surgery of, 35.
Brain, anatomy of, necessity of revising nomenclature of, 296; injury to right side of, followed by wasting of muscles on left side, 42.
Brain-tumor or hysteria, 624.
Bram, I., dreams and dreamers, 799.
Breast, cancer of, acute, 298; cancer of, inoperable, practical method of treatment for, 265; cancer of, preoperative roentgenological examination in, 426; cancer of, successful irradiation of, 1089; glands, secretion of, 1052; tumors of, 1140.
Breathing, deep, 1159.
Breathlessness in soldiers suffering from irritable heart, 913.

Diversional therapy in mental disease, 1028.
Diverticula, vesical, diagnosis and treatment of, 1094.
Diverticulitis of descending and pelvic colon, 833.
Doctors, preparedness, and Red Cross, 466.
Doctors' sons in Lincoln administration, role of, 762.
Dog, nephropathy, spontaneous chronic of, 156.
Dorrance, G. W., an intermaxillary splint, 674.
Draper, J. W., and Lynch, J. M., a consideration of the intestinal toxemias from the standpoint of physiological surgery, 969.
Dreams and Dreamers, 799.
Drennan, J. G., is an angina rather than tonsilitis the precursor of acute rhelmatism? 1032.
Dressing, antiseptic, harmless, 264.
Dropsy, cardiac, renal, and hepatic, treatment of, by Karell cure, 127.
Drueck, C. J., proctitis, 369.
Drug action, study of, 427; addicts and their treatment, 238; dangerous, records of prescriptions for, 724; habit, 185; habit-forming, use of, by soldiers, 683; habit problem, 831; intoxications, morbidity of, 462.
Ducts and glands, vulvovaginal, pathology of, 832.
Ductless glands, disease of, and internal secretions in relation to obesity, 1091; recent studies on, 998; relation of, to optic nerve disturbances, 1036.
Duodenal tube as factor in diagnosis and treatment of gall-bladder disease, 27.
Duodenum, increased dilatability of, significance of, 673; ulcer of, 876; ulcer of, diagnosis of, 997; ulcer of, etiology of, experimental studies of, 389; ulcer of, perforating, 38; ulcer of, treatment of, with scarlet red, 152; ulcer of, recurrent symptoms after operation for, 389.
Dysentery amebic, 1049; amebic, carriers of, 430; amebic, neuritis following emetine treatment of, 601; and dysenteriform diarrhea, 736; bacillary, epidemiology of, 1006; convalescent from, considered from preventive standpoint, 474; leucocyte counts in, 723; observations on, 958.
Dsypnea, cardiac, 33; in heart disease, relation of vital capacity of lung to, 302.
Dystonia musculorum deformans, 601.

E

Ear, discharging, 588; relation of vertigo and seasickness to, 206; suppuration of, hexamine in, 826.
Eclampsia, a preventable disease, 414; and albuminuria, relation of secretion of mammary glands to, 1052; and fractured basis cranii, 1080; eye lesions in, 1169; puerperal lumbar puncture in, 516; treatment of, 662.
Ectopic pregnancy, diagnosis and treatment, 1053.
Eczema, food reactions, anaphylactic, and, 741; treatment, war, for, 880.
Edema, hard, due to trauma and phlebitis, 694.
Efficiency, effects of, fatigue on, 1077.
Einhorn, M., the care of digestion, 893.
Elastometer, 422.
Electric current, curing scars by, 1125; high frequency, contra-indications to use of, 1008; high-frequency, in treatment of uterine fibroids and prostatic enlargements, 1141.

Electrocardiogram, changes in form of, relation of, to functional derangements of heart muscle, 33.
Electrolysis in treatment of gonorrhea, 1036.
Electrotherapeutic applications, contact in, 1008.
Electrotherapeutics, facts and fallacies concerning, 699.
Elliott, G. R., the present status of chronic multiple arthritis, with special consideration of infection as an etiological factor, 529, 666.
Embolism, cerebral, consequent on gunshot injury to carotid arteries, 779; fat, in bone surgery, 472.
Emetine, use of, 601.
Emotions, explanation of some disorders supposed to have origin in, 303.
Empyema of thorax, treatment, operation of, 89; treatment of, by bismuth paste, 117.
Encephalitis following salvarsan injection, 937.
Encephalopathica paludica, 560.
Endarteritis, pulmonary, infective, 645.
Endocarditis, colloidal silver in, 1169; experimental, 302, 1086; septic, injection of ensol, recovery, 781.
Endocrine glands, rôle of, in mental disease, 1056.
Endothelioma, diffuse, enveloping spinal cord, 260.
Enema, ammonia as, 264.
Energy index of circulatory system, 475; metabolism of cretin, 480.
Enteric fever, crossed hip reflex in, 734; fever, diagnosis of, by agglutinin reaction, 647.
Enteric-like fever in Sudan, 384.
Enterococcus in trench fever and allied conditions, 867.
Enterocolitis, protozoic, in Middle West, 1052.
Enzyme action and insects, luminous, 440.
Epidemics, control of, 427.
Epidemiology and preparedness, 277.
Epilepsy, 602, 956; bacillus isolated from, 779; bacillus of, Reed's, 602; blood and its vessels in, 566, 955; blood cultures in, 733; blood in, 20; classification of, 399; constipation and intestinal infection in, 779; criminal, 697; etiology of, 1165; first case in which abdominal surgery was suggested for relief of, 294; frequency of in offspring of epileptics, 864; idiopathic, 1174; Jacksonian, cautery treatment of, 646; pathogenesis and treatment of, 602; toxic manipulations of, and their treatment, 602; treatment of, 252.
Epileptic myoclonus, 950.
Epstein, S., treatment of flat-foot in old patients, 720.
Ergophobia, plea for less, 617, 653.
Ergot, indications for use of, 17.
Erysipelas treated with diphtheria serum, 374.
Erythema multiforme leading to death by uremia, 685.
Eskimo village, tuberculosis in, 663.
Esophagus, stricture of, 65.
"Esquillectomie," subperiosteal, primary, in treatment of fractures, 735.
Ether analgesia, 343; pneumonia, relation of, to pelvic and abdominal surgery, 872.
Ensol, intravenous injection of, in septic endocarditis, 781.
Evidence, expert, 593, 813, 947.
Examiner, medical, full duty of, 562; medical, relation of, to medical director, 563.
Excreta, disposal of, in rural schools, 580.
Exercise for prevention of subinvolution and retroversion, 662; problem of, in treatment of tuberculosis, pulmonary, 617, 653.
Exophthalmos, traumatic pulsating, 207.
Expert opinion as to cause of injury, 1123; testimony as to malpractice in adjustment of splints, 813; testimony based on evidence, 593.
Exudate from trauma, removal of, 1008.
Eye and orbit, injuries of, 208; blood pressure in diseases of, 17; drops, solvent for preservation of, 1102; effects of heat on, 341; injuries related to workmen's compensation, 765; lesions of, due to tear-producing gas, 694; lesions of, in nephritis and eclampsia, 1169; paralysis, posttyphoid, 1137.
Eyeball, tension of, relation of, to choked disk, 732.

F

Fainting attacks in children, 290.
Fallopian tube, left, found in left femoral hernia, 958.
Fancy-work for surgeons, 111.
Fat, as hemoplastic in renal and plastic surgery, 1141; embolism in bone surgery, 472.
Fatigue and its effects on efficiency, 1077.
Fear, rôle played by, in diseases of stomach and intestine, 1072.
Febricula, subfebrile temperature and, 1159.
Feces and urine, peril from, at front, 961; bacteriology of, in diarrhea of infants, 1087; human, Spirochæta eurygyrata in, 119; incontinence of, 700.
Fee, size of, and value of examination, 562.
Feeblemindedness, tuberculosis in relation to, 556.
Fees, medical, schedule of, 108; of young practitioners, 947.
Feet, cold, of legislators, 110; weak, prevention and treatment of, during pregnancy and puerperium, 1074.
"Female" remedies, action of, on excised uterus of guinea-pig, 383.
Femur, fracture of neck of, treatment of, 690.
Ferran on bacteriology of tuberculosis, 773.
Ferrivine in syphilis, effect of, 165.
Fertility, excessive, 386.
Festus, lumbar puncture of, during podalic version, 1127; in utero, attitude of, 83.
Fever, cerebrospinal, meningococcus in, 913; cerebrospinal, origin and prevention of, 1087; enteric, crossed hip reflex in, 734; enteric, diagnosis of, by agglutinin reaction, 647; enteric-like, in Sudan, 384; five-day, etiology of, 914; part of syndrome of toxemia, 471; Salonica, 508; syphilitic, 569; trench, 431, 912, 1088; trench, enterococcus in, 867; typhoid (see Typhoid Fever); typhus (see Typhus Fever); undulant, pathological anatomy of, 638; Volhynia, 376; Volhynia, cause and transmission of, 1135.
Fibrillation, auricular, 848; treatment of, 724.
Fibroids, uterine, 1008; uterine, degenerating, 965; uterine, treatment of, by high-frequency electricity, 1141; uterine, removal of, with recovery, 430.
Fibromyoma uteri and cardiovascular disease, 787; 100 consecutive cases of, submitted to operation, 87; operative treatment of, 87; Finger, septic, 518; disarticulations of, reflex manifestations following, 870.
First aid, symposium on, 873.
Fischbein, E. C., a classification of the epilepsies, 399.
Fischer, L., a note on poliomyelitis, with its preparalytic symptom, 194; notes on the diagnosis of abdominal distention in children, 932.
Fish, J. B., climate; its use and abuse in the treatment of tuberculosis, 591.
Fistula, fecal, closure, by extraperitoneal method, 878; in ano, 1090.
Five-day fever, etiology of, 914.
Flat-foot, treatment of, in old patients, 720.
Focal infection in relation to certain dermatoses, 342.
Food reactions, anaphylactic, in skin diseases, 295, 741.
Fordyce, J. A., syphilis of the nervous system, 575.
Forearm prosthesis, 344.
Formaldehyde, action, physiological and toxic of, 471.
Forman, J., and Scott, E., primary carcinoma of the lungs, 452.
Foot, gangrene of, 35; soldier's, and treatment of common deformities of foot, 29.
Ford, J. S., employment of persons in the arrested stage of tuberculosis, 1154.
Foreign bodies, localized, anatomical position of, 28.
Fourth disease in Italy, 904.
Fractures, compound, treatment of, 875; deformed union and non-union of, 874; gunshot, treatment of, 343; in children, 52; nail extension in, 778; of long bones, treatment of, 1142; plates and bone grafts in, 595; reduction of, early, 690; spontaneous, Roentgen studies of, 1143; treatment of, by wide primary subperiosteal "esquillectomie," 735.
Frambœsia, late sequelæ of, 912.
France, bone surgery in, 964.
Friedman, H. M., mental hygiene, 884.
Frog skin, grafting with, 1088.
Frontal lobes, expanding lesions of, diagnostic value of retrobulbar neuritis in, 911; lobes, lesions of, 764.
Frost, L. C., bacterial etiology of poison-oak dermatitis (rhus poisoning), 1121; hexamethylene tetramine as fuel, 995.
Function, disorders of, practical hints on, 959.
Furuncles in soldiers, treatment of, 915.
Furunculosis, treatment of, 792.
Future, speculations for the, 1007.

G

Gall-bladder disease, diagnosis, chemical, of, 830; disease of, duodenal tube as factor in diagnosis and treatment of, 27.
Galvanism, cerebrospinal, treatment of shell shock, 1001.
Galyl, experiences of, at Royal Naval Hospital, 297.
Gamma rays of radium, action of, on cancers of pelvis, 100.
Gangrene, diabetic, 700; gas, at casualty clearing stations, 734; of foot, 35; peripheral, inoperable, 1103, 1139.
Garbat, A. L., sensitized typhoid bacteria (typhoid sero-bacterins), 1145.
Gargle for adults, 616.
Gas asphyxiation, iodine and, 736; gangrene at casualty clearing stations, 734.
Gasoline, phlegmons, produced by injections of, 694; troubles of English physicians, 857.
Gastroenterology and surgery, 455.
Gastroenterostomy, x-ray in, 1089.
Gastrohydrorrhea in cirrhosis of liver, 302.
Gastrointestinal tract in diabetes, 603; tract, operations on, after-care of patients in, 700.
Gastroptosis treated by gastropexy, 559.
Geneva, cerebrospinal meningitis in, 1038.
Genital organs, females, internal, syphilis of, 568; prolapse, ill-treatment of, 78.
Genitourinary tract, chronic infections of, relation of, to obscure internal disorders, 1094.
German army, disease in, 199.
"Germano-medical sacerdotalism," 440.
Giardia (Lamblia) intestinalis, pathogenicity of, to men and animals, 431.
Gilbert, J. A., dogmatic physiology, 311.
Gillian operation, modified, 831.
Glands, bronchial, tuberculosis of, 822; bronchial, tuberculosis of, relation of, to diagnosis of pulmonary tuberculosis, 324; ductless, diseases of, in relation to obesity, 1091; ductless, recent studies in, 998; ductless, relationship of, to optic nerve disturbances, 1036; ductless, transplantation of, 253; endocrine, in mental disease, 1056; mammary, secretion of, 1052; mesenteric, tuberculosis of, 872.
Glaucoma, corneoscleral trephine operation for, infection following, 723.
Gleason, W. S., the crucial age of man, 881.
Globus pallidus, atrophy of, 214.
Glucose formation from protein in diabetes, 346.
Gluteal fold in sciatic neuritis, 558.
Glycuronuria and its variations, 432.
Goiter, genital, 789; cystic, removal of third lobe of, 822; exophthalmic, 163, 790; exophthalmic, treatment of with radium, 334; ligation of superior pole of thymus in operation for, 875; medical treatment of, 822; ossification, disturbances of, in, 46; pathological changes in sympathetic system in, 263; pathology, experimental of, 565; treatment of, by x-ray, 821.
Gold, colloidal, in typhoid fever, 869.
Gonococcus, genealogy of, same as that of meningococcus? 1053; requirements of, for natural and artificial growth, 63.
Gonorrhea, a curable scourge, 1132; and complications, 382; cutireaction in, 982; in women, 426; sepsis after, 988; treatment of, by electrolysis, 1036.
Goodwin, H. F., and Keogh, C. H., esophageal stricture, 65.
Gout, relation of, to nephritis, 76.
Granuloma pyogenicum, 16; ulcerating, treatment of, by antimony, 734.
Graves' disease (see Goiter, exophthalmic).
Gray, E. A., thrombophlebitis in the tuberculous, with autopsy, 636.
Greeley, H., cultivation of the organisms of vaccinia, variola, and varicella, 265.
Greenberg, G., cystoscopy as a diagnostic aid in spinal cord diseases, 634.
Greene, J. S., agitophasia associated with agitographia, 754.
Grip, epidemic of, 911.
Grossman, J., a plea for the prevention and the treatment of weak feet occurring during pregnancy and the

puerperium, 1074; fractures in children, 52.
Grossman, M., a study of the newer physical signs in the diagnosis of early pulmonary tuberculosis, 855.
Growth in early childhood, troubles of, 869.
Gulliver, F. D., eye injuries as related to workmen's compensation, 765.
Gunshot fractures, treatment of, 343; wounds, infected, salt-pack treatment of, 604; wounds of abdomen in pregnant women, 786; wounds, treatment of, by packing salt sacs, 28.
Gynecology and obstetrics, constitutional factor in, 610; operations in, standardization of definite procedures during, 832.
Gynocardate of soda, in leprosy, 959.

H

Haas, S. V., adrenalin in poliomyelitis, 425.
Haberman, J. V., brain-tumor or hysteria, 624.
Habit, drug, 185; forming drugs, use of, by soldiers, 683.
Hagemann, J. A., rhinal premonstration of tuberculosis, 1157.
Hair-matrix carcinoma, 98.
Hammett, F. S., medical education in chemistry, 503.
Hands and feet, ringworm of, 515.
Harrison anti-narcotic law, 593; construction of, 506.
Hartz, H. J., complete transposition of viscera, with report of two cases, 1027.
Hassin, G. B., histopathological changes in five cases of myelitis, 619.
Hay-fever, cause, treatment, and prevention of, 95; direct and indirect, 603; ragweed pollen in nasal secretion in, 672; therapeutics of, 731.
Head colds, results and treatment, 567; deformities of, mentioned in the Talmud, 18; injuries in war, 385.
Headache of hypertension, daily morning, 639.
Health boards, powers of, 682; education of general public, 956; insurance (see insurance, health); preparedness for, 1131.
Heart and active service, 647; dilatation of, following cold bath, 299; disease, clinical experiences in, 921; disease in soldiers on active service, 383; disease, respiratory symptoms in, 520; efficiency of, 913; failing, 828; failure of right side of, as result of pulmonary disease, 165; irritable, breathlessness in soldiers suffering from, 913; irritable, of soldiers, 771, 781; muscle, functional derangements of, relation of, to changes in form of electrocardiogram, 33.
Heat, compresses, easily procured, 662; effects of, on eye, 341; in treatment of cancer of uterus, 609; in treatment of some forms of cavity carcinoma, 872.
Hecht-Weinberg reaction in syphilis, 742.
Heise, F. H., physics of percussion and auscultation of the chest, 191.
Heliophobia, 1114.
Heliotherapy in tuberculosis, abdominal, 654.
Hematuria and pyuria, 1156; symptomless, surgical problem of, 39.
Hemiplegia of long standing, treatment, orthopedic, of, 118.
Hemolysis, Kelling test for, in cancer, 898.
Hemopathies, 560.
Hemophilia, calcium metabolism in, 478.
Hemoptysis as symptom, 294.
Hemorrhage, cerebral, prodromal symptoms of, 991; intracranial, of newborn, treatment of, 115; subdural, after trauma, 691; uterine, *x*-ray treatment of, 611.
Hemorrhoids, injection treatment of, 384, 662; internal, surgical treatment of, under local anesthesia, 1141.
Hemostatic, thromboplastin solution as, 1132.
Heredity, menace of mental deficiency in, 471.
Hernia caused by electric shock, 682; cerebri, treatment of, 385; cure, painless, radical, for, under local anesthesia, 1173; diaphragmatic, strangulated, 518; femoral, left, left Fallopian tube found in, 958; in light of accident, 1091; inguinal, attached to cord, etc., 833; inguinal complications and sequelæ of operation for, 383; inguinal, operation for, 39; umbilical, and lipectomy, 86.
Herpes corneæ "febrilis," 340; of cornea in influenza, 368; zoster, development of, in cases of chorea treated with autogenous vaccine, 1086.
Herz, L. F., personal experiences in contract practice, 849.
Heterophoria in children, 208.
Hexamethylenamine, excretion of, by damaged kidneys, 821.
Hexamethylene tetramine as fuel, 995.
Hexamine, value of, in aural suppuration and in meningitis, 826.
Hinsdale, G., hydrology in military practice, 751.
Hip, Charcot's disease of, bilateral, 1046; fractures and other injuries of, 39; fractures of, 1094; fractures, treatment of, 690.
History, personal, 433.
Hodgkin's disease, leucemia, lymphosarcoma and, 262.
Hog-cholera virus, immunizing effect of, on swine, 303.
Hoover, F. P., the importance of blood pressure to the eye specialist, 17.
Hormone equation of psychoses, 843.
Horsemint, thymol from, 439.
Hospital, charitable, liability of, 66; control of infectious diseases of infancy and childhood, 613; economics of, surgeons' responsibility of, 872; efficiency, danger to, from diphtheria carriers, 481; interne, plea for, 726; management and mismanagement, 873; organization in rural Pennsylvania, 874; treatment of chorea, simple, 645.
House-fly, poisoned bait for, 528.
Hulst, H., some aspects of special interest bearing on the Roentgenological diagnosis of tuberculosis of the lungs, 712.
Humerus, fractures of, 426.
Hungary, military quarantine stations of, 852.
Hunger pain, significance of, 699.
Hydrocephalus, cure or arrest of, 1158.
Hydrology in military practice, 651, 751.
Hydrophobia in foxes of Alaska, 826.
Hydrotherapy in treatment of convalescents, 1056.
Hygiene, industrial, report of committee on, 943; mental, 470, 645, 884; mental, movement, 471.
Hyperemesis gravidarum, treatment of, 1035.
Hypersensitization, states of, protein extracts in, 381.
Hypertension, arterial, 757; headache, daily morning, of, 639; treatment of, 1008.
Hypnotic suggestion, military cases treated by, 958.
Hypochrondria, 195.
Hysterectomy for fibroids, 200 consecutive, with recovery, 430; obstetrical abdominal, 778; vaginal, 163.
Hysteria, clinical delimitation of, 546; or brain-tumor, 624.
Hysteromyomectomy by morcellation, 610.

I

Icterus, chronic, splenectomy in, 36; familial, in new-born, 479; from picric acid poisoning, 869; hemolytic, congenital and acquired, observations on, 1, 40; infections, with febrile recrudescence, 649; 289 cases of, observed in ambulance service, 782.
Ichthyol, Swiss, 1170.
Ileus, post-operative paralytic, absence of muscular tone in etiology of, 833.
Immune reactions, relation of lipoids to, 654; specific character of, 656.
Immunity—allergic skin reactions as index of, 657; results—from use of diphtheria toxin-antitoxin mixtures and the use of the Schick reaction, 741.
Immunization, universal, 372.
Indigestion, intestinal, of children, treatment of, 830.
Individualism and decadence, 346.
Infancy, accidents and diseases of early weeks of, 349; care and feeding during first month of, 350.
Infant feeding potato flour in, 1088; intussusception, acute, in, 731; malnutrition, 847; meningitis in, 480; mortality as index to social welfare, 357; new-born, care of, symposium on, 347; premature, hospital care of, 438; protein sensitization in, 477; scurvy in, and pasteurized milk, 352; vaginitis in, 477.
Infection, focal, as related to systemic disease, 603; focal, clinical phases of, 1054; location of focal points of, 565.
Influenza, aural complications of, 1165; in infant, with unusual complications, 437; nose and throat sequelæ of, 1165.
Injuries, burial, in trenches, 960; cause of, expert opinion as to, 1123; common to policemen and firemen, and first-aid treatment, 873.
Insane, indigent, care of, 697.
Insanity, alcoholic, as defense to homicide, 788; alcoholic, in Kansas, 636.
Insecticides, use of, against lice, 825.
Insects, luminous, and enzyme action, 440.
Insurance, accident, industrial, surgical aspects of, 39; application, false statements in, 299; health, 683; health, discussion on, 905; health, from viewpoint of physician, 382; health, in relation to public health, 692; life, and albuminuria, 1091; life, and thinness, 521; life, as specialty, 562; life, concealment of disease in, 1003; life, consideration of rectal and colonic diseases in, 1091; life, in tropics, 562; life, medical selection for, 1003; medicine, future of, 433; medicine, probable future evolution of, 286.
Internal secretion and relation to nervous disorders, 700.
Intestine and stomach, diseases of, rôle played by fear in, 1072; diseases of, consideration of, in life insurance, 1091; cancer of, radical operations for cure of, 82; chronic conditions in, and ileocecal valve, 821; congenital inflammation, deformation, and defunctionalization of, 80; disorders of, arising from protozoal infection, 118; infection of, in epilepsy, 779; large (see Colon); obstruction of, 82; obstruction of acute, 473; obstruction of, cause of death in, 582; paralysis of, after resection for gunshot injuries, 255; secretions of, clinical study of, 1084; stasis of, chronic, 872, 920; stasis of, chronic, autointoxication from, 901; stasis of, fallacy of, 1068; stasis of, treatment of, by physical measures, 1008; tumors of, malignant transformation of, 537; venous stasis in, 1005.
Intoxicants, illegal prescriptions for, 197.
Intoxications, drug, morbidity of, 462.
Intramine in syphilis, effect of, 165.
Intravenous therapy, 746.
Intussusception, acute, in infants, 731.
Inversion, visceral, 157.
Iodide medication, spinal fluid during, 912.
Iodine and gas asphyxiation, 736.
Ionization, bipolar, in treatment of inoperable carcinoma, 585, 1008.
Iritis and general practitioner, 732.
Irrigator, rose, 1087.
Italy, alcoholism in, 1050.
Ivy poisoning, autotherapy in, 910.

J

Jacksonian convulsion, features of, 212.
Jacobi, A., Latin and ancient Greek for modern doctors, 927.
Jaundice, chronic obstructive, operative treatment of, 816; dissociate, 263; from trinitrotoluol poisoning, 1048; hemolytic, splenectomy in, 36; infective, 734.
Jaw, fractured, treatment of, 596.
Jelliffe, S. E., the physician and psychotherapy, 852.
Johnson, F. M., report of an old case of parenchymatous nephritis, 1075.
Johnson, J. C., gastro-enterology and surgery, 455.
Johnston, H., tetanus antitoxin in poliomyelitis, 292.
Joints, fractures of, nails and screws in, 778; infections, secondary, of, in acute medical ailments, 604.
Jones, W. R., Wassermann reaction in two hundred and fifty-one tuberculous dispensary cases, 418.
Judson, Dr. Adoniram Brown, the late, 554.

K

Kahn, A., an apparatus for the direct and continuous transfusion of blood, 675.
Kahn, M. H., report of the committee on industrial hygiene of the Retail Dry Goods Association, 943.
Kapp, M. W., painless and shockless childbirth; twilight sleep, 241.
Kalaazar in Europeans, treatment of, by tartar emetic, 1047.
Karell cure, contraindications to, 119; in treatment of cardiac, renal, and hepatic dropsies, 127.
Kean, J. R., doctors, preparedness, and the Red Cross, 466.

Maher, S. J., Connecticut, a student of tuberculosis, 229.
Malaria and quinine, 385; control of, by treatment of carriers, 263; in Rome, history of study of, 649; in Salonica, 519; paralysis, general, due to, 519; recrudescence of, in ancient foci in France, 915.
Malignant disease about mouth, treatment of, by combined methods, 999; transformation of benign intestinal growths, 537.
Mallory, W. J., coins and medals in medicine, 495.
Malnutrition, infant, 847.
Malpractice, 154; cases, expert evidence in, 18, 66; insufficient evidence of, 419, 770; in treating fractured arm, insufficient evidence of, 66.
Mammary glands, secretion of, 1052.
Man, crucial age of, 881, 917.
Maniac, shall we punish? 772.
Marat, 704.
Marple, Dr. Wilbur R., the late, 466.
Martyr, medical, to infantile paralysis, 870.
Massage, pelvic, 691.
Massey, G. B., treatment of inoperable carcinoma by bipolar ionization, 585.
Mastoid disease, Streptococcus mucosus Capsulatus as cause of, 864.
Mastoiditis, anomalous cases of, 811; diagnosis of, by x-ray, 344.
May, A. H., a consideration of the opsonic technique as a possibility of evidence of leucocytic inhibition, 196.
Mead, K. C., is infant mortality an index to social welfare? Scandinavia's reply, 357.
Measles and scarlet fever occurring simultaneously, 480; observations on, 480; pertussis, and pneumonia, 480.
Meat, tainted, medical evidence as to effect of eating, 1123.
Media, artificial, effect of addition of fresh human blood serum to, 558.
Mediastinum, middle, extraction of bullet from, 473.
Medical books as evidence, 988; director and local examiner, co-operation of, 120; education in chemistry, 503; evidence as to damages, 461; examiner, obligation of, 299; expert, use of books to contradict, 947; mind, 718; preparedness, 111; medical profession and campaign against venereal disease, 1167; services, value of, 419; teacher, reflections of, 76; women in history and present-day practice, 341; work and war, 19.
Medical Corps of the U. S. A., as a career, 1106.
Medical Reserve Corps, U. S. A., 549, 1041; value of, 725.
Medication, sublingual, 1037.
Medicine as practised by Chinese, 364; coins and medals in, 495; in New York City in the 60's, 938; in University of Warsaw in past, 960; insurance, future of, 433; insurance, probable future evolution of, 286; movements in, 74; practice of, what constitutes, 18; practice of, Wisconsin law, 813; practice of, without license, prosecution for, 18; practising without license, 813; primitive, 768; privately-feed, inadequacy of, 457.
Medico-educational problems in treatment of atypical children, 1005.
Medium, nutrient, for bacteriological purposes, 254.
Meltzer, S. J., protection against infection in poliomyelitis, 292.
Meningitis, cerebrospinal, epidemic, etiology of, 517; cerebrospinal, in Geneva, 1038; cerebrospinal, treatment of, by congestion, 23; hexamine in, 826; in infants, 480; meningococcus, 612; serum, anti-standardization of, 743; tuberculous, simulating prodromic period of multiple sclerosis, 1050; tuberculous, tuberculin in, 904.
Meningococcus, carriers, disinfection of, 1134; carriers, disinfection of, nasopharyme of, 255; genealogy of, same as that of gonococcus? 1053; in cerebrospinal fever, epidemic, 913; inhibitory action of saliva on growth of, 166.
Mental capacity, privileged communications as to, 1076; deficiency, menace of, 471; disease and mental defect, 216; disease, Abderhalden reaction in, 260; disease, diversional therapy in, 1028; disease, rôle of endocrine glands in, 1056; hygiene, 884; hygiene, major divisions of, 645; hygiene movement, meaning of, 471; pitfalls of adolescence, 996; preparedness, 470.
Menus, educational, 509.
Meralgia paræsthetica, 1001.
Mercuric chloride poisoning, antidote in, 857; succinimide in poliomyelitis, 249.
Mercury, anaphylaxis to, 804; bichloride of, and mercurialized serum, Comparative Toxicity of, 566; effect of, in mouth, 889; intraspinal injections of, reactions following, 76; perchloride of, poisoning by absorption from vagina, 825; poisoning, calcium sulphide an antidote for, 29; treatment, prolonged, in general paralysis, 200.
Mesentery, glands of, tuberculosis of, 872.
Metabolism, basal, in disease, studies of, 25; calcium, in case of hemophilia, 478; diseases of, chronic, prevention of, 616; diseases of, in relation to obesity, 562; energy, of cretin, 480; in diabetes, 1044; infant, studies of, method of preparing synthetic milk for, 439; oxaluria not a disease of, 1049.

Metacarpal bone, first, fracture and dislocation of, 539.
Metastases which follow treatment of tumors with x-rays and radium, 386.
Metchnikoff, recollections of, 344.
Meyer, A., complement-fixation in pulmonary tuberculosis, some clinical observations, 232.
Mexico, antityphus sanitation in, 335.
Michie, H. C., tuberculosis survey of an Alaska Eskimo village, using children under the age of 15 years as an index, 663.
Midwifery, meddlesome, in renaissance, 86.
Military education, universal, medical aspect of, 902; practice, hydrology in, 651.
Milk and communicable diseases, 760; citrated, for infants, 20; condensed, history of, with note on its therapeutical use, 284; control, municipal, modern methods of, 392; cow's, idiosyncrasy to, 645; grading, 589; oxygenated, 565, 1085; pasteurized, and infantile scurvy, 352; supply of London, 1080; supply of Pennsylvania, what can be done to improve? 698; synthetic, preparation of, for studies of infant metabolism, 439.
Mind, hygiene of, 470.
Minor, C. L., problem of rest or exercise in the treatment of pulmonary tuberculosis; a plea for less ergophobia, 617.
Misbranding, medical evidence of, 856.
Miscarriage, relation of syphilis to, 569.
Montgomery, D. W., treatment of mercurial stomatitis, 889.
Moore, S. E., dangers and complications of tonsillectomy, 972.
Moral turpitude, offenses involving, 1076.
Morbidity—and mortality of childhood, 173; and mortality, surgical, operative judgment as factor in, 788; of drug intoxications, 462.
Morgan, W. G., gastric aspirator, 947.
Morowitz, B. F., military quarantine stations of Hungary, 852.
Morphine, two little known facts about, 420.
Morris, R. T., pronunciation of poliomyelitis, 820.
Mortality and morbidity of childhood, 173; and morbidity, surgical, operative judgment as factor in, 788; infant as index to social welfare, 357; statistics for 1915, 1144.
Moses, H. M., present treatment of diabetes mellitus, 1069.
Mother, effect of nutrition of, on child, 297; syphilis in, 351.
Mount, L. B., lupus erythematosus and tuberculosis, a survey of the literature, 983.
Mouth, infections, chronic, of, 603; inflammation, mercurial, of, 889; malignant disease about, treatment of, by combined methods, 999.
Moving pictures in teaching technique of surgery, 919.
Murmur, introcranial, of long duration, 777; cardiac, modifications of, under influence of ocular compression, 961.
Murphy, Dr. John B., appreciation of, 337, 833.
Murphy button in strange situation, 335.
Muscle, changes in, after nerve section, 254; substitution operation for congenital palpebral ptosis, 125; tone, absence of, factor in etiology of postoperative paralytic ileus, 833.
Muscles, interossei, action of, 518; wasting of, on left side, following injury to right side of brain, 42.
Myasthenia gravis pseudoparalytica, 1170.
Myelitis, histopathological changes in, 619.
Myelo-erythrocytoma, mediastinicum, 1155.
Myers, S. W., treatment of pollomyelitis, 114.
Myocardium, efficiency of, 913.
Myomectomy and hysteromyomectomy by morcellation, 610.

N

Nail and screws through joint surfaces in autografts and in fractures into joints, 39, 778; extension in fractures of lower extremity, 39, 778.
Narcotics, administration of, to relieve pain and cure drug habit, 461; prescriptions of unusual amounts of, 506; users of, as witnesses, 813.
Nasopharnx, disinfection of, in meningococcus carriers, 255.
Nausea and vomiting after nitrous oxide-oxygen anesthesia, 1030; and vomiting of pregnancy, control of, by injection of Corpus luteune extract, 1167.
Navy, health of the, 1126.
Negligence, liability of private hospitals for, 637.
Negro psychology, 332; syphilis in, 34.
Nephrectomy for tuberculosis of kidney, 1142.
Nephritides, classification, prognosis, and treatment of, 175.
Nephritis, acute azotemic in troops, 1136; acute, systolic pressure in, 209; calcium deficiency in, 906; chronic, action of diuretics in, 302; chronic, curability of, 829; chronic, treatment of, 880; eye lesions in, 1169; in aged, 75; parenchymatous, old case of, 1075; relation of gout to, 76; value of laboratory tests in diagnosis and treatment of, 31.
Nephropathy, spontaneous, chronic of dog, 156.
Nerve anastomosis, intradural, in poliomyelitic paralysis, 116; and mental shock, care of cases of, coming from overseas, 28; cells, effect of activity on histological structure of, 253; disorders, internal secretions and, 700; optic, disturbances of, relation of ductless glands to, 1036; section, changes in muscle after, 254.
Nervous system as influenced by high altitudes, 382; diseases of, bacteria in, localization of, 31; injuries of, types of, seen at base hospital, 258; relation of, to therapy in tuberculosis, pulmonary, 564; syphilis of, 206, 575; syphilis of, treatment of, 257, 948; war and, 211.
Neuralgia, facial, cure of, by removal of appendix, 873; trifacial, treatment for, 486; trifacial, treatment of, by diathermia, 1152.
Neuritis and myositis, recurring, localization of streptococcus in animals from case of, 742; peripheral, following emetine treatment of dysentery, amebic, 601; retrobulbar, diagnostic value of in expanding lesions of frontal lobes, 911; sciatic, gluteal fold in, 558.
Neurosis, torsion, 879.
Neuropsychic affections in war, 1085.
Neuro-surgical service, selected problems from, 258.
Newborn, conditions in, 349; hemorrhage, intracranial of, treatment of, 115.
New Jersey, Medical Society of the State of, history of, 124.
New York State, typhoid fever in, control of, 651.

Obstetrician and pediatrist, correlation of, 348.
Obstetrics, conservation in, 115; posture in, 84; relation of syphilis to, 567; surgery of, 85.
Occupational diseases, among iron and steel workers, 384; diseases, problem of, 829.
Oculocardiac reflex, ocular compressor for, 695.
Oil, mineral, in treatment of infected wounds, 548; olive, homogenized, 438.
Old, art of growing, 1054.
Olive oil, homogenized, 438.
Omentum, free transplantation of, 35.
Operations, necessary refusal of, by soldiers, 695.
Ophthalmology, desiccation method in, 117.
Opinion evidence, 770.
Opium alkaloids, action of, on vomiting center, 303; possession of, 533; regulation of sale of, 593.
Oppenheim's disease, 601.
Opsonic technique as evidence of leucocytic inhibition, 196.
Optic nerve, disturbances of, relation of ductless glands to, 1036.
Orange peel as chologogue and peristaltic stimulant, 264.
Ossification, disturbances of, in cretinism, endemic, and goiter, 46.
Osteoarthritis, treatment, operative, of, 208.
Osteochondritis deformans coxæ juvenalis, evolution of, 472.
Osteomalacia, 828.
Osteomyelitis in children, 789.
Osteospondylitis, localized, 428.
Otitis, acute, fatality following, 548; media, chronic suppurative, 472; media, cleansing in, 616; media, irrigation in, 1102.
Outpatient work, efficiency of, 164.
Ovary, cysts of, contents of, 116.
Overcrowding in institutions for infants and children, 612.
Oxaluria not a disease of metabolism, 1049.
Oxford standard agglutinable cultures, 780.
Oxycephaly in two brothers, 480.
Oxygen gas, injection, intravenous, of, as therapeutic measure, 558; nascent, in treatment of infected wounds, 989; supply as factor in disease, 731.
Oysters, purification, artificial, of, 375.
Ozone, surgical uses of, 958.

P

Pachon's method, application of, to study of cardiopulmonary circulation, 343.
Palsies, birth, 126.
Paludism and quinine, 385; primary, in Salonica, 519.
Pancreas and metabolism in diabetes, 1044; changes in, in latent syphilis, 263; function of, in cirrhosis of liver, 803.
Pan-sinusitis, complicated with acute suppurative appendicitis and mastoiditis, 637.
Pappataci, 685.
Paralysis agitans, pathological findings of, 42; agitans syndrome, special form of, 214; agitans, treatment for, 1166; agitans, treatment of, by continuous bath, 367; agitans, treatment of, with parathyroid gland, 105; following inoculation against rabies, 879; general, anterior spinal, in soldier, due to malaria, 519; general, mercury treatment in, 200; in spinal region, upper, following anterior poliomyelitis, 39; infantile (see Poliomyelitis), 246; obstetrical, 257; ocular, posttyphoid, 1137; spastic, familial, 214.
Paranoia, induced, 807.
Parathyroid glands, 67; in treatment of paralysis agitans, 105.
Paratyphoid fever and bacilluria, 1089; fever, convalescent from, considered from preventive standpoint, 474; fever, revaccination against, 464.
Paresis, general, treatment of, with arsenobenzol, 556; treatment of, by intraventricular injections of diarsenolized serum, 163.
Parker, Peter, founder of modern medical missions, 341.
Parturition, chloroform in, 85; obstructed, retraction of uterine muscle

associated with, 913; painless, 612; painless and shockless, 241; posture in, 85; statistics of deaths due to, 119.
Pasteur Institute in Tunis, antirabic service of, for 1915, 750.
Pasteur treatment of rabies in Lyon's district, success of, 70.
Patella, fractures of, treatment of, 690.
Pathologist, mistakes revealed by the, 245.
Pedersen, J., syphilis of the bladder, 235.
Pediatrist and obstetrician, correlation of, 348.
Pellagra, 181, 750; and sensitization to maize and sugar-cane products, 595; etiology of, 262; its etiology and treatment, 416; scrotal sign in, 816; scrotum in, 816.
Pelvis, cancers of, action of gamma rays of radium on, 100; contracted, treatment of, 963; diseases of, diagnosis of, 787; infection of, in women, 83; lavage, 884; lesions, inflammatory, of, treatment of, by surgical measures, 83.
Pemphigus neonatorum, epidemics of, in Chicago, 1000.
Peptone, substitute for, 254.
Percival, J. B., primitive medicines; a short sketch on emetics and purgatives, 768.
Percussion and auscultation of chest, physics of, 191; deep, value of, in diagnosis of subacute intraabdominal disease, 373.
Perforation, acute, surgical management of, 1054.
Pericarditis, occurrence and diagnosis of, 864.
Peritonitis, acute general hemorrhagic, 298.
Perkins, C. W., fracture and dislocation of the proximal end of the first metacarpal bone and fracture of the trapezium, 539.
Personality, behavior, and conduct of convicts in Siberian prisons, 1057.
Perthes's disease, causes and treatment of, 418.
Pertussis, measles, and pneumonia, 480; treatment of, 782.
Petery, A. K., induced paranoiac conditions, 807.
Pharmacy in Russia, 948.
Pharyngitis, chronic granular, treatment of, 792.
Philanthropic possibility, 156.
Philbrick, I. C., inadequacy of privately-feed medicine, 457.
Phlegmons produced by injection of gasoline, 694.
Phthisis, see Tuberculosis, pulmonary.
Physical reserve force, development of, 288.
Physiology and psychology and their euphoristic harmony, 462.
Physiology, dogmatic, 311.
Physician and prevention of industrial accidents, 25; and psychotherapy, 362.
Physics of percussion and auscultation of chest, 191.
Picric acid in war surgery, 647; poisoning, icterus from, 869.
Pitfield, R. L., typhoid vaccine in poliomyelitis, 203.
Pituitary extract in post-abortion curettage, 991; pharyngeal, clinical possibilities of, 441.
Pityriasis lichenoides, chronica, 207.
Plague, bubonic, arising in England, 648; student and victim of, 968.
Plantar hyperhidrosis, treatment for, 486.
Plates and bone grafts in fractures, 595.
Pleurisy, apex, signs of, 605.
Pneumococci, types of, in infants and children, 828; types of, specificity of, 743.
Pneumonia and typhoid fever, 1088; ether, relation of, to pelvic and abdominal surgery, 872.
Pneumonia, lobar, acute, treatment, specific of, 828; lobar, coagulation time in, 301, 1046; lobar, epidemiology of, 742; pertussis, and measles, 480; treatment for, 486; treatment, non-specific, of, 828; treatment of, by bacterins, sensitized, 746.
Pneumothorax, artificial, results of, 865; spontaneous, without symptoms, 654; treatment in pulmonary tuberculosis, 342.
Poison, protein, facts concerning, 655; sale of, French decree against, 1090.
Poison-ivy, autotherapy in, 910; dermatitis, bacterial etiology of, 1121; treatment for, 662.
Poisoning, atropine, impromptu diagnosis of, 11; benzol, transfusion of blood in, 33; carbon monoxide, 420; case, evidence in, 856; chlorine gas, treatment of, by venesection, 385; mercurial, calcium sulphide an antidote for, 29; mercuric chloride, antidotes in, 857; mercury perchloride, by absorption from vagina, 825; picric acid, icterus from, 869; protein, animal, clinical manifestations of, 407; ivy, autotherapy in, 910; ivy, dermatitis, bacterial etiology of, 1121; ivy, treatment for, 662; trimitrotoluol, jaundice from, 1048.
Poliomyelitis, acute anterior, 67, 793, 863; abortive and nonparalytic cases, 168; adrenalin chloride intraspinal injection of, in, 202; adrenalin in, 425; after-care of, 989, 1045, 1066; and rat, 641; and Vincent's method of prophylaxis, 246; autotherapy in, 427; causation of, theory as to, 936; cerebrospinal fluid in, bacteriology of, 957; clinical types of, 167; control of next epidemic of, 328; diagnosis and treatment of, 142, 1175; epidemic of, 169, 170, 330, 777; epidemic, afterthoughts on, 691; epidemic, bacteriological observations on, 692; epidemic, etiology of, 771, 823; epidemic, management of, from neurologist's viewpoint, 934; epidemic, possibly milk-borne, 922; epidemic, recent, management of, from neurologist's standpoint, 1176; management of, present methods, 1175; epidemic, symptomatology and diagnosis of, 250; immune human serum in treatment of, 823; in adult, fatal case of, 373; in Brooklyn, 73; in Switzerland, 507; infectivity of, 245; laboratory aids in diagnosis of, 169; management of, with view of minimizinz ultimate disability, 705, 739; medical martyr to, 870; mercuric succinimide in, 249; municipal control of, 473; nerve anastamosis, intradural in paralysis following, 116; panic, 464; paralysis in upper spinal region following, 39; paralysis of, treatment of, 646; preparalytic symptom of, 195; prevention of, 337, 426; preventive and cure for, 338; prognosis in, 296; protection against infection in, 292; quinine in, 377; reflections on, 545; report of 77 cases treated with intraspinal injections of adrenalin chloride, 540; report on, 860, 1062; serum treatment of, 429; suggestion in, 160; symposium on, 167; tetanus antitoxin in, 292; tonsillectomy in, 1139; transmission of, 167; treatment of, 114, 157, 203, 341, 379, 1008, 1009; treatment of, by transfusion of citrated normal blood of adults, 587; treatment of, prolonged, 430; treatment of, some aspects of, 1064; typhoid vaccine in, 203; with observations on thirty cases, 472; pronounciation of, 820.
Polycythemia, liver in, 303.
Porter, W. H., infant malnutrition, 847.
Posture in obstetrics, 84.
Potassium iodid, effect of, on luetin reaction, 516.
Potato flour as addition to infant feeding, 1088.
Practice, contract, personal experiences in, 849.
Practitioners, drugless, 243.
Pregnancy, care of woman during, 298; complications of, 340; ectopic, diagnosis and treatment, 1053; extrauterine, 777, 1112; following bilateral salpingectomy, 206; nausea of, control of, by injections of corpus luteune extract, 1166; toxemia of, 1078; toxemia, nephritic of, 340; weak feet, occurring during treatment of, 1074.
Prenatal care, need and value of, 348.
Preparedness, epidemiology and, 277; mental, 470.
Presidents, long lives of the, 657.
Prisons, Siberian, convicts in, 1057.
Proctitis, 369.
Professional services rendered to another, liability for, 511.
Prophylaxis, hepatic, 773.
Prolapse, genital, ill-treatment of, 78.
Prolapsus ani in adults, 295.
Prostate gland, cancer of, radium in treatment of, 957; human, in middle age, 3; hypertrophy of, and senile involution, 1079; hypertrophy of, treatment of, by high-frequency electricity, 1141.
Prostatectomy, 556.
Prostatics, drainage of, as preliminary to operation, 909.
Prosthesis, forearm, 344.
Protein extracts in states of hypersensitization, 381; glucose formation from, in diabetes, 346; poison, facts concerning, 655; poisoning, animal, cilinical manifestations of, 407; sensitization in infancy, early symptoms suggestive of, 477.
Protoza, diseases due to, treatment of, by tartar emetic, 959; infection of intestine by, 118.
Pseudo-lævulosuria, diagnosis of, 166.
Psoriasis following inflammation of tonsils, 106; pathogenesis of, 340.
Psychiatry, treatment of soldiers by, 109.
Psychiatric needs of a large community, 42.
Psychic affections in war, 1085; disturbances, functional, in light of war, 374.
Psychoanalysis, 859.
Psychology, negro, 332; of diseases of respiratory tract, 645; physiology and, 462.
Psychoses, functional, problem of, 263; hormone equation of, 843.
Psychotherapy, physician and, 362.
Ptomaine poisoning, expert opinion as to, 988.
Ptosis, palpebral, congenital, muscle substitution operation for, 125.
Public health, health insurance in relation to, 692.
Puerperal infection, urine in, prognostic significance of, 176.
Pulmonary artery, sclerosis, isolated, of, 210.
Pulse form, significance of, 33.
Purgatives in diseases of liver, 1002.
Purism in medical writings, plea for, 69.
Pus, laudable, 815; laudable, in wounds, septic, 604; Samuel Cooper's teaching on, 862.
Putnam, J. M., medical mind, 718.
Pyelitis, chronic colon bacillus, treatment of, by pelvic lavage, 76; mode of infection in, in infancy, 435.
Pyloroplasty for pyloric stenosis, congenital, 1141.
Pylorus, cancer of, radical cure of, 561; leiomyoma of, 822; stenosis of, pyloroplasty for, 1141.
Pyorrhea alveolaris, 514; and Vincent's disease, 684; systemic disturbances from, 475.
"Pyrexia" or "trench fever," 1088.
Pyrexias, trench, prevention and treatment of, 693.
Pyuria and hematuria, 1156.

Q

Quarantine stations of Hungary, military, 852.
Quartz lamp, Cooper Hewitt in treatment of alopecia, 1008; light in cutaneous diseases, 557.
Questions, hypothetical, 461.
Quinine, paludism and, 385.

R

Rabies, human, treatment of, 287; paralysis following inoculation against, 879; Pasteur treatment for, success of, in Lyons district, 70; service of Pasteur Institute in Tunis for 1915, 750.
Rachitis, calcium content of blood in, 478.
Radiology, insufficient protection in, 788.
Radiotherapy in arthritis, chronic, 427; in gynecology, value and limitation of, 877.
Radium, a palliative, 831; action of gamma rays of, on inoperable cancers of pelvis, 100, and x-ray treatment of cancer of cervix, 1143; efficiency in non-malignant surgical conditions, 47; in carcinoma, gastric, 26; in laryngology, 50; in treatment of cancer of uterus and vagina, 611; in treatment of carcinoma of prostate and bladder, 957; in treatment of goiter, exophthalmic, 334; metastases following treatment of tumors by, 386; therapy, some clinical aspects of, 411.
Radius, head of, subluxation of, 117.
Ragweed pollen in nasal secretion of hay-fever cases, 672.
Railroad hospital association, liability of, 197; phase of first aid, 873.
Rat and infantile paralysis, 644.
Ravn, E. O., and Bedford, E. W., diagnosis of so-called sciatica, 1033.
Rectocele, repair of, operation for, 1175.
Rectovesical transillumination, cystoscopic, 778.
Rectum, gunshot wounds of, 859; lesions of, influence of, on abdominal conditions, 873; operations on, under local anesthesia, 691.
Red Cross preparedness and, 466.
Reed's bacillus of epilepsy, 602.
Re-education of crippled soldiers, 990.
References, verify your, 732.
Reflex disturbances and cerebral insufficiency, 783; hip, crossed, in enteric fever, 734; manifestations following disarticulations of fingers, 870.
Reitzfeld, I., congenital club-foot; clinical study of a series of 21 cases with remarks on treatment, 897.
Remedies, new, scarce, old substitutes for, 210.

Respiratory exchange, with description of respiratory apparatus for clinical use, 24, tract, diseases of, psychology of, 645; tract, effects of exposure to cold upon experimental infection in, 301; tract, prophylactic and therapeutic inoculation in affections of, 744.
Rest or exercise, problem of, in treatment of tuberculosis, pulmonary, 617, 653.
Resuscitation apparatus, 116.
Retrospections, medical and otherwise, 1109.
Retroversion uterus, radical cure of, 1131.
Rhachialbuminimetry, 991.
Rheumatism, acute, angina rather than tonsilitis precursor of, 1032.
Rhinoplasty, 1139.
Rhus poisoning, 662, 910, 1121.
Rice diet, 331.
Ringworm of hands and feet, 515.

Scheppegrell, W., cause, treatment and prevention of hay-fever, 95; ragweed pollen in the nasal secretion of hay-fever cases, 672.
Schick reaction in infants, 481; practical value of, 761.
Schmitz, H., action of gamma rays of radium on deep-seated and inoperable cancers of the pelvis, 100.
School-children, rural, care of, 903.
Schools, rural, disposal of excreta in, 580.
Sciatica, sign of, new, 1038; simulation of, 773; so-called, diagnosis of, 1033.
Sclerosis, amyotrophic lateral, 214; disseminated, 481; isolated, of pulmonary artery, 210; multiple, meningitis, tuberculous, simulating, 1050; of spinal cord, subacute combined, 215.
Scott, E. and Forman, J., primary carcinoma of the lungs, 452.
Scurvy, cure for, 616; infantile, and pasteurized milk, 352; infantile, clinical and experimental study of, 523; infantile, diet and growth in, 435.
Seaman, L. L., surgeons wanted for the European armies, 730.
Seasickness, 595; relation of, to ear, 206.
Secretions, gastric, fractional determination of, 866; internal, relation of, to obesity, 1091; of digestive tract, clinical study of, 1084.
Semen, examination of, 965.
Senile involution, hypertrophy of prostate and, 1079.
Sensations, differentiation and organization of, 211.
Sensory disturbances of cerebral origin, 211.
Sepsis after gonorrhea, 988; focal, 26; lenta, 1049; puerperal, and colloidal silver, 606; puerperal, treatment of, 877.
Septicemia, diagnosis and treatment of, 744.
Serbia, experiences in, during war, 918.
Sero-bacterins, typhoid, 1145.
Serum, antimeningitis, standardization of, 743; as substitute for broth for bacteriological purposes, 959; disease, renal function in, 263; mercurialized, 566; mercurialized, and bichloride of mercury, comparative toxicity of, 566; reactions following treatment with sensitized and non-sensitized bacteria, 744; therapy in poliomyelitis, 429; therapy in trichinosis, 429.
Sex characteristics, virilism and inversion of, 432; determination of, 42, 1056.
Sexton, L., observations of tetanus with report of a successfully treated case, 945; treatment of wounds, 680.
Sheehan, J. E., case of pan-sinusitis, complicated with acute suppurative appendicitis and acute mastolditis, 637.
Sheffield, H. B., epidemic poliomyelitis; preliminary report on 33 cases, 330.
Shell shock, cerebrospinal commotion from, 1137; etiology of, 165; study of, 693; treatment of, 343, 1001.
Shock, glandular and humeral, repercussion in, 1137; shell, cerebrospinal commotion from, 1137; etiology of, 165; study of, 693; treatment of, 343; treatment of, by cerebrospinal galvanism, 1001.
Shoes, physiological and therapeutic, 340.
Shortening technique, new, 253.
Silver, colloidal, and puerperal sepsis, 606; colloidal, in endocarditis, 1169.
Simulation, 606.
Sinuses, accessory, nonoperative treatment of, 469; chronic suppurative, treatment of, by bismuth paste, 117.
Skeleton splinting, simple system of, 166.
Skin diseases, anaphylactic food reactions in, 295; diseases, autoserum injections in, value of, 75; diseases, focal infection in, 342; diseases, occupations as contributing factors to, 205; diseases, treatment of, with quartz light, 557; frog, grafting with, 1088; reaction of, to stroking, 381; reactions, allergic, as index of immunity, 657; tuberculosis of, ultraviolet rays in, 1169.
Skull operations, primary, on, 605.
Sleep, detoxicating action of, 463.
Smith, J. G., fatal case of poliomyelitis in an adult, 373.
Smith, J. W., Jr., case of auricular fibrillation, 848.

Syncope after administration of diarsenol, 163.
Syndrome, a new, 984.
Synesthesialgia, 727.
Synnott, M. J., fallacy of intestinal stasis, 1068.
Syphilis, and tuberculosis, pulmonary, contact points between, 514; arterial hypertension due to, results of treatment in, 516; as factor in vague stomach disorders, 34; astasia-abasia in, 879; congenital, present conception of, and its modern diagnosis, 14; cynic's view of, 904; effect of, on teeth, 445; experimental, 569; ferrivine and intramine in, effect of, 165; fever of, 569; heredity, in second generation, 870; hereditary, in third generation, 869; immunity of Arabs to, 831; in mother, 351; in negro, 34; latent, pancreatic changes in, 263; luargol or "102," new remedy for, 781; luetin in diagnosis of, 685; menace of, 162; occurrence of, in University of Michigan obstetrical and gynecological clinic, 568; of bladder, 235; of genital organs, internal female, 568; of lung, 25, 654; of lung, or tuberculosis? 1135; of nervous system, 206, 575; of nervous system, central, intraspinal treatment of, 868; of nervous system, treatment of, 257, 948; of uterus, 569; problem among confined criminals, 981; relation of, to miscarriage and fetal abnormalities, 569; relation of, to obstetrics, 567; relation of, to social problems, 568; test for, 557; treatment, intensive, of, 516; treatment of, at Providence City Hospital, 241; treatment of, by salvarsan, 701; treatment of, by salvarsan, controlled by Wassermann test, 701; Wassermann reaction in, 744; Wassermann and Hecht-Weinberg reactions in, 742.
Syringocncephalmyelia, 258.
Syringomyelia and arthropathy of shoulder-joint, 879; case of, 42.
Systoles, ventricular, premature, and their clinical significance, 33.

T

Tabes dorsalis, acroataxia and proximoataxia in, 42; associated with severe anemia, 42; cardiac crises in, 722; resemblance of, to disease of pituitary gland, 41.
Talmud, deformities of head mentioned in, 18.
Tartar emetic, in treatment of kala-azar, 1047; in treatment of protozoan diseases, 959.
Teacher, medical, reflections of, 76.
Teeth, disease of, in nursing women, 1047; heredosyphilitic stigmata of, 445; infections of, diagnosis of, by Roentgen rays, 1008; Roentgenograms of, significance of apical shadow in, 198.
Telangiectasia, hemorrhagic, hereditary, 651.
Temperature, absence of rise of, following administration of diagnostic doses of tuberculin, 1001; axillary, 1171; subfebrile, and febricula, 1159.
Tendon sheaths, rubber tissue, 200.
Testicle, intraabdominal, sarcoma of, 38; undescended, in children, 909.
Testimony, physician's, competency of, 637.
Tetanus, antitoxin in poliomyelitis, 292; cure of, by serum, 869; delayed appearance of, 29; from ocular wounds, 1083; late, prolonged, contractures of, 915; recovery from, 557; report of successfully treated cases, 945; toxin, distribution of, 155; trench foot, 27.
Tetany, calcium content of blood in, 478.
Thecitis, occupational, 732.
Therapeutics, physical, in medical college curriculum of to-day, 557; teaching of, as branch of applied physiology, 251.
Therapy, meaning of, 564.
Thermometer, clinical, as carrier of infection, 865; medical, control of, 735.
Thinness and life insurance, 520.
Thiosinamine, indication for use of, 376.
Thompson, W. G., inoperable peripheral gangrene, 1103.
Thorax, disease of, and surgical therapy, 32; empyema of, treatment, operative, of, 89.
Thrombophlebitis in tuberculous, 636.
Thromboplastin solution as hemostatic, 1132.
Thymic disturbance in adult, 736.
Thymol from horsemint, 439.
Thymus gland, hypertrophy of, roentgentherapy in, 731; ligation of superior pole of, in operation for goiter, 875.
Thyroid, active constituent of, 263; active constituent of; its chemical nature and function, 821; cases, metabolic studies of, 821; disease, ambulatory types of, 895; function of, 375; gland, surgery of, 821; resection of, 790.
Tic mechanism, simple, 164; spasmodic, produced by cerebello-pontine tumors, 212.
Tissues, human, and bacteria, comparative resistance of, to certain germicidal substances, 866.
Tobacco and acne necrotica, 915; habits of school children, 422.
Toluol, 428.
Tongue, medication under, 1037.
Tonsillectomy, dangers and complications of, 972; in poliomyelitis, 1139; under novocaine, 1116.
Tonsillitis or angina, precursor of acute rheumatism, 1032; treatment of, 1056.
Tonsils, Connellan-King diplococcus infection of, 207; faucial, in singers, 1165.
Tourniquet, rigid or elastic, 160; two views of, 19.
Toxemia, chronic intestinal, and appendicitis, chronic, association and differentiation of, 567; fever part of syndrome of, 471; intestinal, from standpoint of physiological surgery, 969; nephritic, of pregnancy, 340; of pregnancy, 1078; preeclamptic, 357; urinary, 295.
Toxin, intestinal, and circulation, 254; tetanus, distribution of, 155.
Tracheobronchitis due to nitric acid fumes, 910.
Tracheotomy in adults, 386.
Tract, pyramidal, function of, 258.
Transfusion, blood, apparatus for direct and continuous, 675; blood, group tests in, 208; blood, in anemia, pernicious, 37; re-, in hemorrhage, abdominal, 1136.
Transplantation of bone, 255; of bone, principles to be observed in, 498.
Trapezium, fracture of, 539.
Trauma, disabilities following, 259; exudate from, removal of, 1008.
Traumatisms of war, decalcification consecutive to, 735.
Trench fever, 431, 912, 1088; fever, papataci, and dengue, 685; fever, relation of enterococcus to, 867; foot tetanus, 27; pyrexias, their prevention and treatment, 693; warfare, effect of, on renal function, 693.
Trephine operation, corneoscleral, for glaucoma, infection following, 723.
Trichinosis, 558, 733; researches in, 987; study of epidemic of, 429.
Trinitro-toluene, effects of on women workers, 517; poisoning, jaundice from, 1048.
Trismus during serum sickness, 518.
Trophism, theory of, Waller's law and, 1089.
Trypsin-broth in blood cultures, advantages of, 430.
Tube, fallopian, left, found in left femoral hernia, 958.
Tubercle of choroid, diagnostic value of, 693.
Tuberculin, absence of rise of temperature following administration of diagnostic doses of, 1001; dispensary, 1118; in diagnosis of tuberculosis, 867; in treatment of lymphnoditis, tuberculous, 745; in treatment of meningeal tuberculosis, 904; in treatment of tuberculosis, pulmonary, 745; use of, in general practice, 297.
Tuberculins and vaccines, 298.
Tuberculosis, abdominal, heliotherapy in, 654; acquirement of active immunity by treatment with von Ruck's vaccine against, 135; and cancer, 804; and lupus erythematosus, 983; anti-, movement in Massachusetts, 1165; arrested stage, employment of persons in, 1154; at Vanderbilt Clinic, 702; bacteriology of, 772; Bonime's modification of Koch's treatment of, 320; chemotherapy of, 288; clinical, what constitutes, in adults? 514; complement fixation in, 1000; crusade against, woman's duty in, 61; diagnosis of, by tuberculin, 867; diagnosis of, early, 822; extrapulmonary, infrequency of, under tropical sunlight, 1136; fallacies about, 1085; hospital a county purpose, 770; hospitals for, in Massachusetts, problems of, 776; in children, diagnosis, clinical and radiological, of, 824; in relation to feeblemindedness, 556; in rural communities, 776; league of Massachusetts, 776; lipase in urine in, 262; meningeal, tuberculin in, 904; of bronchial glands, 822; of bronchial glands, relation of, to diagnosis of tuberculosis of lungs, 324; of kidney, nephrectomy for, 1142; of mesenteric glands, 872; of skin, ultraviolet rays in treatment of, 1169; of spine, treatment of, 1139; points of attack of, 422; pulmonary, among soldiers, 478; pulmonary, anatomic form and posture important factors in the treatment of, 251; pulmonary, advantages of special training in, 652; pulmonary, and appendicitis, 652, 654; pulmonary, and chronic affections of nasal fossæ, differential diagnosis between, 431; pulmonary, and common sense, 294; pulmonary, and dental caries, 606; pulmonary, and syphilis, contact points between, 514; pulmonary, complement-fixation in, 232; pulmonary, Connecticut, a student of, 229; pulmonary, diagnosis of, 815; pulmonary, diagnosis of, by Roentgen rays, 712; pulmonary, diagnosis of, relation of tuberculosis of bronchial glands to, 324; pulmonary, diagnosis of, without stethoscope, 652; pulmonary, early, newer physical signs in diagnosis of, 855; pulmonary, early, percussion in, 251; pulmonary, or syphilis of lung? 1135; pulmonary, pneumothorax treatment of, 342; pulmonary, study of, in development of clinical medicine, 653; pulmonary, therapy in, relation between nervous system and, 564; pulmonary, treatment of, by tuberculin, 745; pulmonary, treatment of, problem of

rest or exercise in, 617, 653; pulmonary, thrombophlebitis in, 636; pulmonary, treatment of, use and abuse of climate in, 591; pulmonary, treatment of, with vaccines, bacterial, 824; pulmonary, *x*-rays in diagnosis of, 830; renal, diagnosis of, 903; rhinal premonstration of, 1157; survey of Alaska Eskimo village, 663; treatment, home, of, 244; von Pirquet reaction in, 826; Wassermann reaction in, 418.
Tullidge, E. K., frozen limbs and their treatment in the present war, 11.
Tumor, abdominal, transient, in child, 437; carotid, 814; cerebellopontine, tic, spasmodic, produced by, 212; malignant, of liver, diagnosis of, 1050; metastases following treatment of, with *x*-rays and radium, 386; of breast, 1140; of cord, cervical, 259; of intestine, malignant transformation of, 537.
Twilight sleep, 156, 241.
Typhoid and paratyphoid infections, distribution of, among enteric fevers at Mudros, 648; bacteria, sensitized, 1145; dysentery group, agglutination reaction of bacilli of, with normal sera, 209; fever, 471; fever, agglutination reactions in, 780; fever and pneumonia, 1088; fever and typhophors, 829; fever, colloidal gold in, 869; fever, diagnosis of, bacteriological, 1088; fever, injury as cause of, 813; fever in New York State, control of, 651; fever, multiple, 858; fever, revaccination against, 464; fever, simulation of, by leucemia, 560; fever, studies in, 743; fever, treatment of, by intravenous injections of sensitized typhoid vaccine sediment, 262; para, and baciullria, 1089; serobacterins, 1145; vaccination for policy-holders, 299; vaccine in poliomyelitis, 203.
Typhus, anti-sanitation in Mexico, 335; fever, 960; 1037; fever, treatment of, with colloidal metal, 694.

U

Ulcer, duodenal (see Duodenum, ulcer of); gastric (see Stomach, ulcer of).
Ulna, dislocation, habitual, of, 878.
Ultraviolet rays in tuberculosis of skin and mucosæ, 1169.
Umbilicus, methods of treating, 349.
Urea, toxic effect of, on normal individuals, 302.
Uremia, consideration of types of, 31; erythema multiforme, leading to death by, 685.
Ureter, evolution of, after nephrectomy, 1169; stricture of, 116.
Ureteritis, acute, due to streptobacillus urethræ of Pfeiffer, 1136; notes on, 439.
Urethra, injuries of, in war, 559.
Uric acid reaction in saliva, 960.
Urine, bacteriology of, of children, 480; blood and pus in, 1156; incontinence of, in women, 570; in puerperal infection, prognostic significance of, 176; in tuberculosis, lipase in, 262.
Urochromogen and diazo reactions, 1102.
Urticaria, giant, chronic, cure by anti-anaphylaxis, 1171.
Uterus, and vagina, operations on, without anesthetic, 1119; cancer, inoperable, of, cystoscopy and radiation in, 210; cancer of, and treatment, 608; cancer of, operation, extended, for, 608; cancer of, treatment of, by heat, 609; cancer of, treatment of, by radium, 611; cancer of, treatment of, by surgery, 87, 832; cervix, cancer of, treatment of, by radium and *x*-rays, 1143; cervix, carcinoma of operation for, 825; excised, of guinea-pig, action of various "female" remedies on, 383; fetus in, attitude of, 83; fibroid, degenerating, of, 965; fibroids of, 1008; fibroids of, removal of, with recovery, 430; fibroids of, treatment of, by high-frequency elasticity, 1141; fibromyoma of, and cardiovascular disease, 787; fibromyomata of, operative treatment of, 87; hemorrhage from, *x*-ray treatment of, 611; muscle of, retraction of, associated with obstructed labor, 913; precancerous changes in, 611; prolapse of, in nulliparous women, 831; retropositions of, congenital and acquired, 966; retroversion, radical cure of, 1131; rupture of, 785; rupture of, in Cesareanized women, 785; rupture of, with prolapse of intestines, 788; syphilis of, 569; version of, report of 500 cases, 786.

V

Vaccination, aseptic way of performing, 1048; of guinea-pigs with *B. perfringens*, 733.
Vaccine, autogenous, chorea treated with, development of herpes zoster, 1086; Krauss, in treatment of whooping cough, 950; therapy in wounds, gunshot, septic, 1133; treatment, leucocytosis as diagnostic sign in, 657; typhoid, sediment, treatment of typhoid fever by intravenous injections of, 262; von Ruck's acquirement of active immunity by treatment with, against tuberculosis, 135.
Vaccines and tuberculins, 298; bacterial, in treatment of tuberculosis, pulmonary, 824; in acute infections, 282.
Vaccinia, variola, and varicella, cultivation of organisms of, 265.
Vagina, cancer of, treatment of, by radium, 611.
Vaginitis of infants, vaccination, provocative and prophylactic, in, 477; report on, 477.
Valve, ileocecal, and chronic intestinal invalid, 821.
Van Baggen, N. J. P., speech, its culture and refinement; what is done for it in Holland, 502.
Vasomotor disturbances of upper air passages, diagnosis and management of, 380.
Vein, portal, wound of, 912.
Venereal disease in Austrian army, 290; disease, medical profession and campaign against, 1167.
Venous stasis, intestinal, diffusion of bacteria and other colloids, 1005.
Verbrycke, J. R., Jr., case of gastric ulcer, 812.
Vermin, body, methods of destroying, 77.
Version of uterus, with report of 500 cases, 786.
Vertebræ, cancer of, 736.
Vertigo and seasickness, relation of, to ear, 206.
Vesical diverticula, diagnosis and treatment of, 1094.
Vincent's disease and pyorrhea alveolaris, 684; method of prophylaxis and infantile paralysis, 246.
Virilism and inversion of sexual characters, 432.
Virus, hog cholera, immunizing effect of, on swine, 303.
Viscera, inversion of, 1571; transposition of, complete, 1027.
Vitamines, a factor in nutrition, 522.
Vitiligo, albinism, leucoderma, 986.
Voice and articulation, American, 381.
Volhynia fever, 376; fever, cause and transmission of, 1135.
Vomiting, acetone therapy of, 914; after nitrous oxide-oxygen anesthesia, 1030; periodical, with acetonemia versus appendicitis, 694; post-chloroformic treatment of, 783; toxic, early morning, in children, 478.
Von Ezdorf, Dr. Rudolph H., the late, 511.
Von Pirquet reaction in schools of Lausanne, 826.
Von Ruck's vaccine against tuberculosis, 135.
Voorhees, I. W., fatality following acute otitis, 548.
Vulvovaginal ducts and glands, pathology of, 832; problem, 477.

W

Wade, H. A., operations on the uterus and the vagina, without an anesthetic, 1119.
Waller's law and theory of trophism, 1089.
War and nervous system, 211; functional psychic disturbances in light of, 374; medical work and, 19; psychic and neuropsychic affections in, 1085; zone, European, recent medical observations in, 318.
Ware, M. W. and Lilienthal, H., recent progress in operative treatment of empyema of thorax, 89.
Warner, F., hair-matrix carcinoma, 98.
Warning, 639.
Warsaw University of, medicine in, in past, 960.
Wasp, sting of, death following, 344.
Wassermann reaction, 107; reaction and Hecht-Weinberg reaction in syphilis, 742; reaction and placental histology in diagnosis of syphilis, 569; reaction, clinical significance of, 701, 744; reaction in 251 tuberculous dispensary cases, 418; reaction, specificity of, 568.
Waste, domestic, collection and disposal of, 858.
Wayland, R. T. and Wayland, C. A., case of laceration of liver, 371.
Weak feet, prevention and treatment of, during pregnancy and puerperium, 1074.
Weil's disease, in army in Flanders, 781; disease, diagnosis of, 1135.
Werdnig-Hoffman, progressive spinal muscular atrophy, 214.
Whitman, R., remarks on anterior poliomyelitis, with reference to principles of treatment and their practical application, 1062.
Whooping cough, treatment of, by Krauss vaccine, 950.
Widal reaction, anomaly in, 517.
Wile, I. S., economic value of speech correction, 583.
Williams, B. G. R., four years' study of the Kelling hemolytic test, 898.
Williams, E. M., lesions of the frontal lobes, 764.
Williams, J. R., clinical methods of measuring acidosis, 223.
Williams, L. R., milk and communicable diseases, 760.
Williamson, L. P., the medical corps of the army as a career, 1106.
Window tent, story of a, 953.
Winston, J. W., eclampsia, a preventable disease, 414; suggestion in prevention of infantile paralysis, 337.
Wittenberg, J., and Schapira, S. W., hematuria and pyuria, 1156.
Wittson, A. J., Saratoga Springs for cardiovascular diseases, 204.
Wolf, H. F., diathermia in the treatment of tri-facial neuralgia, 1152.
Woman, duty of, in antituberculosis crusade, 61.
Women, gonorrhea in, 426; nursing, dental disease in, 1047; medical, in history and present-day practice, 341; pelvic infection in, 83; workers, effects of trinitro-toluene on, 517.
Woodward, Dr. Julius Hayden, the late, 72.
Workmen's compensation law, 698; eye injuries as related to, 765.
Wound dressing, sodium hypochlorite as, 880.
Wounds, bacteriotherapy of, lactic, 1050; cloth embedded in, 1168; disinfection of, Carrel method of, 791; gunshot, infected, salt pack treatment of, 604; gunshot, of rectum, 859; gunshot, septic, vaccine therapy in, 1133; gunshot, treatment of, by packing with salt sacs, 28; healing of, influence of antiseptics on, 77; infected, oxygen in treatment of, 989; infected, treatment of, 1652; infected, treatment of, by physiological methods, 77; infected, treatment of, by hypertonic solutions and mineral oil, 548; infected, treatment of cloth by antiseptic substances in relation to, 825; ocular, tetanus from, 1083; of abdomen, 1000, 1090; of chest, perforating and penetrating, 119; penetrating, of abdomen, 1000; projectile, pleuro-pulmonary, 386; septic, natural history of, 342, 824, 1133; septic, treatment of, plea for ignoring "laudable pus" in, 604; septic, treatment of, with special reference to salicylic acid, 78; stab, of chest, 36; suppurating, treatment of, 517; treatment of, 680; war, infection of, by anaerobes, 1170.
Wright, B. L., mercuric succinimide in poliomyelitis, 249.
Wright, H. W., some aspects of the treatment of infantile paralysis, 1064.
Writer, too-ready, and high cost of paper, 289.
Wynkoop, D. W., theory as to causation of poliomyelitis, 936; reflections on poliomyelitis, 545.

X

X-rays, examination by, in cancer of breast, 426; examination by, in cancer of stomach, value of early, 1025; examination of gastro-enterostomized subject, 1089; in cancer of breast, 1089; in diagnosis, 506; in diagnosis of cancer of stomach, 263; in diagnosis of dental infections in systemic diseases, 1008; in diagnosis of mastoiditis, 344; in diagnosis of tuberculosis, pulmonary, 712, 830; in treatment of hemorrhage, uterine, 611; in treatment of sarcoma of kidney, 437; in treatment of thymus gland, hypertrophy of, 731; in treatment of venereal bubo, 264; metastases following treatment of tumors by, 386; photographs as evidence, 901; photographs, identification of, 1076; picture evidence, 813; pictures, dental, significance of apical shadow in, 198; studies in bone pathology, 1143; therapy, scope and technique of, 1015.

Y

Yankee trick in England, 551.
Yarbrough, J. F., pellagra; its etiology and treatment, 416.
Yeomans, F. C., malignant transformation of benign intestinal growths, 537.

Z

Zigler, M., anaphylaxis to mercury, with report of a case, 805.
